correctly restricted to the practice of this art in the field. In the East falconry has been traced back to a period anterior to the Christian era, and was practised there and also in Europe long before its introduction into Britain. It was known to our Saxon ancestors, and is mentioned in the *Colloquy* of Archbishop Ælfric, written in the 10th century. In the celebrated Bayeux tapestry Harold is represented with a hawk upon his glove; and the Norman nobles, who were as much addicted to hawking as to hunting, gave a great impetus to the sport in England by the importation of falcons (especially jerrfalcones) from abroad, and by the large sums they expended upon this diversion. Henry II. used to send every year for young falcons from the cliffs of Pembrokeshire. Richard I. while in the Holy Land amused himself with hawking at Jaffa, in the plain of Sharon, with hawks which he had brought with him from England. King John used to send to Ireland for his hawks—amongst other places to Carrickfergus, County Antrim, and was especially fond of a flight at the crane with jerrfalcones which he received from the king of Norway. He used to hawk in Dorsetshire and Somersetshire, as appears by entries in the court rolls of payments for the expenses of the journeys. When Edward III. invaded France, he had with him, according to Froissart, thirty falconers, and every day either hunted or hawked as his fancy inclined him. The Paston Letters, written in the reign of Edward IV., give an insight into the ways and doings of English falconers in the middle ages, as do also the various 'Household Books' which have come down to us. Henry VII. used to import his goshawks from France, and Henry VIII.'s love of the sport nearly cost him his life, if we may believe the anecdote told of him in Hall's *Chronicle*. During the reign of Elizabeth hawking was much in vogue in England, and Nichols in his *Progresses* has given some interesting details of the queen's participation in this pastime. James I. was a most enthusiastic sportsman, and gave a great impulse to hunting and hawking in England by inviting those of the French nobility who were the greatest adepts in these field-sports to come over to this country, and compete in friendly rivalry with his own subjects. He was especially fond of kite-hawking with jerrfalcones, and carried this branch of the sport to great perfection on the wide heaths of Royston, Newmarket, and Thetford.

It may be well to correct here an erroneous statement which has been many times repeated in print to the effect that Sir Thomas Monson in the reign of James I. gave £1000 for a *cast*—i.e. for two hawks, the truth being (as stated by Sir Antony Weldon in his *Court and Character of King James*, 1650) that he spent £1000 before he succeeded in obtaining a cast which he considered perfect for kite-hawking.

These were the palmy days of falconry, when the sovereigns on both sides of the Channel (James I. and Louis XIII.) were enthusiastic falconers, giving every encouragement to the sport, when the species of hawk carried was indicative of the rank of the owner, and when the best books were written by English and French masters of the craft.

The disastrous state of the country during the period of the civil wars naturally put an end for the time being to the general indulgence in field-sports; and it may be said that at the Restoration hawking had ceased to be popular, although from that time until the present it has never ceased to be practised by a few admirers of the old sport in various parts of the country. The last member of the royal family, it is believed, who sent for or received hawks from abroad was Frederick, Prince of Wales, son of George II., who occupied the 'palace of Durdans' at Epsom, now a seat of the Earl of Rosebery's, and used to hawk over the downs, where in 1825 there was a spot still known as 'the Hawker.' Fashion, no doubt, had a good deal to do with the decline of hawking, for so soon as the reigning sovereign ceased to take an interest in the sport the courtiers and their friends followed suit. Between the years 1751 and 1791 the third Lord Orford did much to encourage the practice of falconry in England; and during the first quarter of the 19th century Colonel Wilson (afterwards Lord Berners) in Norfolk, and Colonel Thornton, of Thornville Royal in Yorkshire, not only practised game-hawking with great success (as did also Sir John Sebright, who wrote a practical treatise on the subject in 1826), but excelled in those higher branches of the sport, kite-hawking and heron-hawking, which have long since become impracticable by reason of the extinction of the former quarry and the impossibility of securing the requisite conditions for a flight at the latter.

In 1840 the formation of the Loo Hawking Club, whose headquarters were at the summer palace of the king of Holland, kept the sport alive for many years, and several English falconers who kept hawks of their own annually repaired to Loo for the enjoyment of heron-hawking, which was there carried out to perfection by the Dutch falconers Van der Heuvel, the brothers Bots, and the veteran Adrien Mollen. The last owner of heron-hawks in England was Mr Edward Clough Newcome, of Hockwold in Norfolk, a most accomplished falconer, who died in 1871. About this time was formed the Old Hawking Club, and there are now a great many owners of hawks who carry on the old sport with more or less success in different parts of the United Kingdom, look-hawking in the spring and game-hawking in the autumn, the interval being devoted to lark-hawking with merlins and flights with the goshawk at rabbits and hares. It may therefore be said that, although from various causes hawking in England has declined since the days of the Stuarts, it has never actually died out.

The birds employed by falconers belong to two classes—the long-winged, dark-eyed falcons, and the short-winged, yellow-eyed hawks. To the former class belongs the Jerrfalcon, Peregrine, Lanner, Saker, Barbary Falcon, the Indian Shabhin,

the Hobby, and the Merlin; to the latter the Goshawk and Sparrow-hawk. The former take their prey by rising above it in the air, and *stooping* at it from a considerable height, and striking it to the ground; the latter pursue in a straight line, and, overtaking the quarry by superior speed, clutch it, and come down with it. The larger falcons are flown at winged game of all kinds—crows, magpies, rooks, herons, and wild-fowl; the smaller falcons, such as the merlin and hobby, are used for taking larks; while of the short-winged hawks the sparrow-hawk is flown at blackbirds and thrushes, partridges early in the season, and quails, the goshawk taking pheasants, partridges, and wild-fowl, rabbits and hares. With all birds of prey the females are invariably larger and more powerful than the males, and the sexes are consequently selected according to the quarry they have to pursue. Jerfalcons are now rarely employed, partly owing to the difficulty of procuring them, partly because the peregrine falcon is preferred, and experience has shown that except in a woody or inclosed country, where the goshawk and sparrow-hawk are preferable, the peregrine is the most useful of all the birds of prey.

Hawks are either taken young from the nest before they can fly, when they are termed *eyesses*, or are caught later, during the period of their migration, by means of a decoy-pigeon and a bow-net, when they are called *passage-hawks*. The mode of treatment is a little different, inasmuch as the latter have already learned to catch and kill prey for themselves, and only require to be tamed; the former have everything to learn. A passage-hawk on being caught is hooded, and has jesses, or soft leather straps, fastened on her legs. She is then set down on a block of turf to prevent damage to feathers, and fed once a day, at first through the opening of the hood, afterwards with the hood removed. The bird is always fed upon the gloved hand, and gradually learns to step on to it from the perch, increasing the distance daily until she is obliged to fly to reach the fist. The training then commences. The hawk is *called off*, as it is termed, *to the lure*, which means that after tying a long line to the ends of the jesses she is held hooded on the hand of an assistant, until the falconer at the distance of five-and-twenty yards swings the lure to which the bird has been accustomed to come to be fed. The hood being then removed, the hawk flies to the lure, and is exercised in this way for some time daily, until she is sufficiently tractable to be trusted without a line, care being taken not to feed her until she has flown, and always to reward her for coming to the lure with a morsel of the meat with which it is garnished. She is then

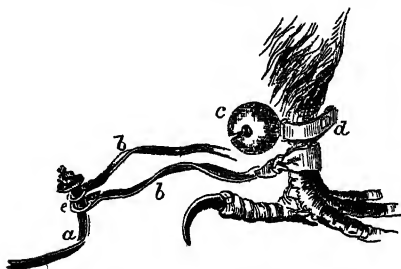

Fig. 1.—Leg and foot of Hawk, showing the method of attaching the jesses and bell:

a, end of the leash; b, jesses; c, the bell; d, bewit; e, varvels.

entered at the quarry at which she is intended to be flown (partridge, rook, or whatever it may be) by first giving her a live bird at the end of a long line, and allowing her to go off the fist and kill it;

eventually the line is dispensed with, and she is flown at wild quarry.

Such, briefly, is the mode of training a passage-hawk. An eyess is somewhat differently treated. A straw-covered platform is put up in some shed or outhouse, and on this the nestlings (which should not be taken too young, or they will turn out *screamers*) are placed, the platform being about as high up as one can reach to feed the birds. They are fed three times a day on fresh lean beef, while growing, to keep up their strength, or *hunger-traces* will appear, like cuts across the webs of the feathers, and the latter breaking will render the birds useless. When they are strong enough and able to fly, jesses are put on the legs, and a spherical brass bell (of Dutch or Indian make) on one leg, fastened just above the *jess* with a little narrow strip of leather termed a *bewit* (see fig. 1). At feeding time, now once a day, they are called to the lure, and, being allowed their liberty for some weeks (in which state they are said to be *flying at hack*), they daily gain strength and wing-power, until the time comes for taking them up and commencing their training, which after this stage does not differ much from the method above described for passage-hawks. When flying at hack, a hawk sometimes becomes wild, wanders away to a distance, and kills game for herself. When this is perceived, a bow-net or other device for snaring is set for her, to which she is decoyed and recaptured. The first operation in training is *hooding*, which, if successfully performed, overcomes much difficulty. It requires some patience and dexterity, and should be practised at first in a darkened room, in which the hawk will be much quieter than in broad daylight. The hood is simply a cap of leather (see fig. 2) made to fit the head in such a

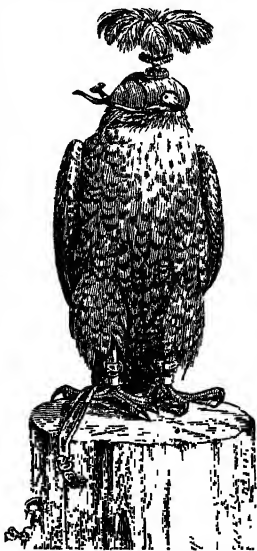

Fig. 2.—Hooded Peregrine on the block:

One end of the leash is attached to the jesses, the other to a ring driven into the side or top of the block; and thus the hawk is prevented from escaping.

manner as to obscure the light, a single aperture only being left, through which the beak protrudes, and a slit behind, which is opened and closed, when the hood is put on and off, by means of *braces*, one pair of which opens, the other pair closes the slit; the eye-pieces, which to prevent injury to the eyes are carefully *blocked out*, are covered for ornament with red or green cloth. By temporarily blindfolding the hawk, the hood causes her to sit perfectly quiet, and prevents her from *bating*, or fluttering, at the risk of breaking feathers, as she would do if frightened by passers-by until gradually accustomed to them.

Allusion has already been made to the jesses, or soft straps of leather (dog-skin is best), which are fastened to the legs of the hawk, by which to hold her on the glove and tie her to the perch or block. These jesses are about 6 inches long, and are never removed when the hawk is flown. In former times *varvels*, or flat rings of silver with the owner's name engraved thereon, were permanently attached to the ends of the jesses, and through

these one end of the leash was passed, the other end being prevented from going through by a leather button. At the present day, however, most falconers prefer using a figure-8 swivel, which is always detached before the hawk is flown.

The *lure*, already referred to, is a device for luring the hawk back to her owner after an unsuccessful flight, and on this account the hawk is early made acquainted with it by being fed upon it daily while being trained. There are various patterns; one of the simplest and most easily made consists of a couple of pigeons' wings tied together on a flat circular leaden weight covered with leather, upon which a piece of raw meat is tied on both sides. The *tabur-stick* and *drawer*, which were formerly used as lures, have long been discarded.

The beaks and claws of wild caught hawks are generally so long and sharp as to require paring or *coping*, as it is termed; but this operation requires to be very carefully performed (the hawk being hooded and held by an assistant), and not more than the tenth of an inch removed, or the efficiency of the beak and claws will be impaired. Indeed some falconers will never cope a hawk, except when the beak is overgrown; and with goshawks especially, which have to hold such powerful prey as hares and rabbits, strong and sharp talons are indispensable.

Eastern falconers carry their hawks upon the right hand; but European falconers always carry them on the left, leaving the right hand free for detaching leash and swivel, and removing and replacing the hood.

The following are some of the technical terms used in falconry. The wings of a hawk are termed the *sails*; the tail, the *train*; the legs, *arms*; the toes, *petty singles*; the claws, *pounces*; the crop, *gorge*; the stomach, *panel*; the pellets of feathers and undigested food which are thrown up after feeding are termed *castings*. A young hawk from the nest is an *eyess*; one that can perch but not fly, a *brancher*; an eyess reared at liberty, a *hack-hawk*; one taken later on migration, a *passage-hawk*; a young hawk in the first year's plumage is called a *red-hawk*, or a *soar*- or *sore-hawk*, from the Fr. *sorel*, 'a reddish-brown colour.' A wild caught adult hawk is a *haggard*. After the first moult a hawk is said to be *intermeued*; when completely moulted, *full sunmed*; when purged of all superfluous fat and in good condition, *enseamed*. A broken feather is repaired by a process termed *imping*; cutting or paring the beak and claws is termed *coping*. The prey when living is called the *quarry* (from the Fr. *curée*); when dead, the *pelt*. A hawk is flown either *out of the hood*—i.e. off the fist—as in rook-hawking, or is *put up*, or *cast off*, as in game-hawking before the game is sprung. In the latter case, when a hawk soars in circles at a height above the falconer's head, she is said to *wait on*. She *stoops* when descending with closed wings from a height at the quarry, *binds* when she seizes it in the air and comes down with it, *carries* when she flies off with it, *rakes off* when she flies straight away without soaring, and *checks* when she changes the bird in pursuit. At home she sits either indoors upon the *perch* or out of doors upon the *block*, and is carried to the field hooded upon the *cadge*, a padded wooden frame of square or oval shape, which is borne by an assistant with the aid of shoulder-straps. In this way six or eight hawks may be carried without difficulty, since, being hooded, they sit perfectly quiet.

The principal works on falconry in English are the treatise on hawking in *The Boke of St Albans* (1486) of Dame Juliana Berners (q.v.), from which very little practical instruction is to be gained; Gervase Mark-

ham, *Gentleman's Academie* (1595), a later version of the last named; Turberville, *Book of Falconrie* (1575-1611); Latham, *Falcon's Lure and Cure* (1615-18 and 1633); Bert, *Approved Treatise of Hawks* (1619); Nicholas Cox, *The Gentleman's Recreation* (1674, and numerous later editions); John Ray, *Summary of Falconry* (1678); Campbell, *Treatise of Modern Falconry* (1773); Sir John Sebright, *Observations on Hawking* (1826); Belanay, *Treatise upon Falconry* (1841); Salvin and Brodrick, *Falconry in the British Isles* (1855 and 1873); Freeman and Salvin, *Falconry* (1859); Freeman, *Practical Falconry* (1869); Harting, *Essays on Sport* (1883), *Hints on the Management of Hawks* (1884), *A Perfect Booke for keepinge of Spar Hawkes* (1886), and *Bibliotheca Accipitraria* (1892); Cox and Lascelles, *Coursing and Falconry* (1892); and Michell, *Art and Practice of Hawking* (1900).

Faldstool, a small desk in churches in England at which the litany should be sung or said. The name is also given to a folding-stool used by Roman Catholic bishops and other prelates.

Falemé, one of the most important tributaries of the Senegal, rises in Futa-Jallon, and after flowing in a northerly direction joins the main stream above Bakel. About 120 miles above its mouth the Falemé is interrupted by rapids and waterfalls. Up to that point it is navigable for small steamers during two months of the year.

Falerii, a city of ancient Etruria, and the capital of the Falisci, was situated west of the Tiber, and north of Mount Soracte. After its capture and destruction by the Romans (241 B.C.), the inhabitants settled on a new site a few miles off. See ETRURIA.

Falernian Wine, so called from *Falernus Ager*, the district in which it was grown—and which lay in the northern portion of Campania, between the Massican Hills and the northern bank of the Volturnus—was one of the favourite wines of the Romans. It is described by Horace as, in his time, surpassing all other wines then in repute. In the time of Pliny Falernian wine had declined in quality. Red Falerno and white is still largely made and exported.

Faliero, MARINO, Venetian general and doge, was born about the year 1274. At the siege of Zara, in 1346, he defeated an army of 80,000 Hungarians, and afterwards, whilst in command of the fleet, captured Capo d'Istria. Subsequently he became ambassador of the republic to Rome and Genoa. He was elected Doge of Venice in 1354. In the following year, dissatisfied, it is said, with the punishment inflicted by a patrician tribunal upon a young noble, Michele Steno, who had publicly insulted the youthful wife of the aged doge, Faliero conspired with the plebeians to assassinate the oligarchy and make himself supreme ruler of Venice. The conspiracy was, however, revealed on the eve of its execution, and Faliero was arrested and beheaded on the 17th of April 1355.

For the true story, see F. Marion Crawford's *Venetian History* (1906) and the *Edinburgh Review* for July 1906, rather than Byron's and Swinburne's tragedies.

Falk, ADALBERT, Prussian statesman and leader in the *Kulturkampf* with the Roman Church, was born at Metschkau, in Silesia, 10th August 1827. Educated for the law, he held various judicial and administrative posts in his native province, until he was appointed Minister of Public Worship and Education in 1872. In this capacity he was mainly instrumental in carrying the so-called May laws (because passed in May 1873, 1874, and 1875), aimed against the excessive influence of the Church of Rome, by limiting the influence of the clergy in the schools, by reorganising the seminaries for the training of teachers, and by defining in a stricter and more comprehensive manner the relations generally of the clergy to the state. When, how-

ever, Bismarck came to bid for the support of the clerical party, in order to carry out his later internal policy, Falk resigned in 1879. Thereafter he lived in retirement, and died 7th July 1900.

Falke, GUSTAV, German poet and novelist, born at Lubeck 11th January 1853, taught music at Hamburg, where he had for friends Liliencron and Delmel, and died 8th February 1916. Falke was late in developing, and holds an intermediate position between the older poets and his younger contemporaries. He was much influenced by Liliencron, who suggested the title of his first book, *Mynheer der Tod* (1891). Many books of lyrics and children's tales followed, characterised by simplicity, feeling for nature, melody of verse and artistic spontaneity of form. Some prefer his novels of Hamburg life to Frenssen's. See his autobiographical *Die Stadt mit den Goldenen Türmen* (1912).

Falkenhayn, ERICH VON, German statesman and general, was born 11th September 1861 near Thorn. He spent some time in China before and after the expedition of 1900. In 1913-15 he was Prussian war minister, and from December 1914 to August 1916, as chief of the general staff, directed the push against Warsaw. His success in the east did not save him from the consequences of failures in the west, and Hindenburg took his place. In 1916-17 he commanded in the invasion of Rumania. He wrote *Die oberste Heeresleitung* (1920) and other books of literary quality, and died 9th April 1922.

Falkirk, a town of Stirlingshire, finely situated on a rising ground in the midst of a populous mineral and manufacturing district, and overlooking an expansive 'carse', is 3 miles SW. of its seaport, Grangemouth, 20 NE. of Glasgow, and 21 WNW. of Edinburgh. Including now the suburbs of Grahamston, Bainsford, Laurieston, and Camelon, it was constituted a parliamentary burgh in 1832, and since 1918 has combined with Stirling and Grangemouth to return one member. Its parish church—the *Eglais Bhreac*, *Varia Capella*, or *Faw* ('speckled') *Kirk* of chartularies and local tradition—was rebuilt in 1810. There are also the county buildings (1868), burgh buildings (1876), town-hall (the former corn exchange, 1859), an equestrian statue of Wellington (1854), a science and art school (1878), the Dollar Free Library (1888), and a hospital. The famous cattle 'tysts' or fairs, where stock was annually sold to the value of £1,000,000, have been largely superseded by the weekly auctions. The iron manufacture is carried on busily at Carron (q.v.). Pop. (1921) 33,308. At Falkirk on 22d July 1298 Edward I. inflicted a disastrous defeat on Wallace, and on 17th January 1746 Prince Charles Edward defeated Hawley. Antonine's Wall (see ANTONINUS PIUS) is the chief antiquity.

Falkland, a royal burgh (since 1458) of Fife, at the north-eastern base of the steep East Lomond Hill (1471 feet), 22 miles north of Edinburgh. Nothing remains of the old castle of the Earls of Fife, in which David, Duke of Rothesay, is believed to have been starved to death by the Regent Albany (1402); but there are extensive and stately remains of the later royal palace (circa 1450-1542), with singularly fine Renaissance details. It was the death-place of James V., and has memories of almost all the other Stewart sovereigns. With the estate and a modern mansion (1844), it was purchased in 1888 by the Marquis of Bute, who thoroughly restored it. Pop. 800.

Falkland, LUCIUS CARY, VISCOUNT, was born most probably at Burford, Oxfordshire, in 1610, son of Sir Henry Cary, himself of literary tastes and a friend of Ben Jonson. His father, created Viscount Falkland in the Scottish peerage in 1620, was the well-meaning but unfortunate lord-deputy of Ireland

from 1622 to 1629; his mother was learned in languages and in the Fathers, was an early friend of Chillingworth, and, while still a girl, became a convert to the Catholic faith, though she did not avow it for twenty years. Lucius went to Ireland with his parents, and had his education at Trinity College, Dublin, succeeded to his maternal grandfather's property at nineteen, according to Clarendon, and soon after married, to his lasting happiness, Letice, daughter of Sir Richard Morrison. But the marriage irritated his father, who had been ambitious of a more splendid match, and moreover seems to have been displeased at the descent of his father-in-law's property to his son. With that instinctive unselfishness, linked with impulsive temper, so characteristic of his nature, Lucius at once offered, but to no purpose, to give up all claim upon the estate; he next crossed to Holland to volunteer into the service of the young republic, but soon returned to devote himself to his studies, especially of Greek. His father's death in 1633 gave him the title, and for a time he lived with his mother and listened dutifully to all her anxious arguments for his conversion. But his rational temper could not find rest in her summary solution of his questionings, and ere long, guided by the resistless intellect of Chillingworth, he reached conclusions as alien, in their large tolerance, to Puritanism as to Papistry. He soon settled down in his house at Tew, in Oxfordshire, to a severe course of study, and to that *convivium philosophicum* or *convivium theologicum* which the loving pen of Clarendon thirty years after described with so peculiar a charm. Hither came constantly the brightest intellects of the university, but sixteen miles distant, as well as the poets and wits from London. In the group of closest intimacy Clarendon enumerates Sheldon, Morley, Hammond, Earle, and Chillingworth, and to these we may add John Hales and the historian himself—great writer and constant friend. There is hardly another picture in our literary history so attractive as that of this 'university in a purer air' under the oaks and limes of Tew, and of the Tusculan disputations there of Falkland, Hales, and Chillingworth, three friends united by so warm a friendship, yet unlike in everything save supremacy of intellect, littleness of stature, and largeness of charity. To this period belong Falkland's pleasing but not striking poems, which were edited by A. B. Grosart in 1871. His *Discourses of Infallibility*, and the longer *Reply to the Answer thereto*, are a truer index to what lay closest to his heart.

For some years high thinking entirely occupied Falkland's mind, but in 1639 we find him offering his sword for service against the Scots, and actually accompanying Essex's expedition as a volunteer. After his return he sat in the Short Parliament for Newport in the Isle of Wight, and was again returned to the Long Parliament for the same place. Here he distinguished himself by his ardour and eloquence in behalf of constitutional liberty, which he felt to be endangered by the high-handed absolutism of Laud and Strafford. Although his innate love of fairness and justice impelled him at first to demand delay in the impeachment of the latter until the charges made could be fully inquired into, he both spoke and voted with the majority on the third reading of the bill of attainder. He took the same part in the question of ship-money, and vigorously attacked the real illegalities of Finch, the Lord-keeper; but, though he assailed the bishops' claims to divine right, he refused to support the abolition of Episcopacy, while willing enough at first to exclude the bishops from the House of Lords. But the popular party moved too fast for his wise and temperate patriotism, and, in his alarm at the threatening

domination of a no less intolerant Presbyterianism he found himself compelled to resist the second Bishops Exclusion Bill.

At the commencement of 1642, after much persuasion, he accepted the secretaryship of state, although he evidently mistrusted the character of the king, and had no share in the counsels of the queen and the inner party that really ruled his actions. It was characteristic of the man that he refused to make use of spies or to open letters; and, as was to be expected, we find him active in the last ineffectual efforts to bridge the ever-widening breach betwixt the Court and the Commons. When the inevitable war broke out he gave his sword loyally to the king, but his heart sank within him to see his much-loved country bleeding in civil strife. There is no more touching figure in our history than this large-hearted patriot in his last few months of life, so real yet romantic is the pathos that enshrines him. Already the shadow of death hung over him, and Clarendon tells us, in the most famous passage of the *History*, how, his cheerfulness and vivacity gone, and even his customary carefulness in his dress abandoned, 'sitting amongst his friends, often, after a deep silence and frequent sighs, he would, with a shrill and sad accent, ingeminate the words "Peace, peace," and would passionately profess that the very agony of the war, and the view of the calamities and desolation the kingdom did and must endure, took his sleep from him, and would shortly break his heart.' On the morning of the battle of Newbury, 20th September 1643, he knew that the hour for which he longed had come. He was cheerful beyond his wont, and put on clean linen as if for a banquet. Placing himself in the front rank of Sir John Byron's regiment, he rode forward to meet his death at a gap in the hedge where the enemy's bullets flew thickest. 'Thus fell that incomparable young man, in the four and thirtieth year of his age, having so much despatched the business of life that the oldest rarely attain to that immense knowledge, and the youngest enter not into the world with more innocence: and whosoever leads such a life need not care upon how short warning it be taken from him.'

See Clarendon, both in the *History* and the *Life*; also S. R. Gardiner's *History*. There is no better account of Falkland than that in chap. 3 (vol. i.) of Tulloch's *Rational Theology in England in the Seventeenth Century* (1872). See also the characteristically urbane yet irritating essay by Matthew Arnold (*Nineteenth Century*, March 1877), with the sufficient reply by Goldwin Smith (*Contemporary Review*, April 1877); and that by Lord Camarvon in the *Fortnightly Review* for November 1882. The *Life* and *Times* by J. A. R. Marriott (1907) defends Falkland from the charge of weakness admitted by Gardiner as by Macaulay.

Falkland Islands, a British colony in the South Atlantic, lying between 51° and 53° S. lat. and 57° and 62° W. long., some 250 miles E. of Patagonia, with which they are geologically connected by a submarine plateau. The group consists of East Falkland and West Falkland, with about 100 small islands. Dependencies are South Georgia (q.v.), and, since 1909, the South Shetlands, the South Orkneys, the South Sandwich group, and Graham's Land. Area, East Falkland, 3000 sq. m.; West Falkland, 2300 sq. m.; and of the 100 small islands, 1200 sq. m. Some of the islets are occupied only by myriads of penguins. Pop. (1871) 811; (1911) 3275; (1921) 2094. The shores are deeply indented with bays and inlets, containing many good harbours; the surface is for the most part undulating (Mount Adam, the highest point, 2315 feet), with numerous small streams and lakes; there are no trees, brown cannel-coal is found, and peat is plentiful. The climate is healthy, resembling that of the Orkneys, characterised by severe

gales and abundance of moisture. The mean temperature is about 42°; the annual rainfall varies from 25 to 27 inches; while the average number of days in the year on which rain falls is about 200. Tussock grass and balsam bog are the principal vegetable products. The chief industries are sheep-breeding and whaling. Wool, frozen meat, live sheep, tallow, skins, and hides are exported to Britain. The capital is Stanley (pop. 1000) on East Falkland. The group appeared (as Ascension Islands) in Spanish charts of 1527-29. Davis was driven amongst them in 1590. Sir Richard Hawkins (Sir John's son) coasted them in 1594, and called them Hawkins' Maiden-land. A Dutch navigator was here in 1598. Captain Strong named them in 1690 after Lord Falkland, then treasurer of the navy. They were occupied by France in 1764, but ceded to Spain in 1767. In 1765 Commodore Byron had taken possession of part of the islands, and this nearly led to war between Spain and Britain. But in 1771 Spain yielded the islands to Britain. In 1826 a German household established itself in East Falkland, but was driven out by a U.S. corvette in 1831 for showing hostility to American sealers. But the group was definitively occupied by Britain in 1833, and has since remained a British possession. It is a crown colony, administered by a governor, with an executive and a legislative council. In 1908 the Dependencies of the Falkland Islands were set up, and in 1917 their boundaries were defined. Between 20° and 50° W. long. they include everything south of 50° S. lat., and between 50° and 80° W. long. everything south of 58° S. lat.—that is, the South Orkneys, South Shetlands, South Georgia, the Sandwich group, as well as a sector of the Antarctic continent, of which Graham Land is part. South Georgia is a very important whaling centre; the South Shetlands and South Orkneys are also notable whaling stations. See Lucas's *Historical Geography of the British Colonies* (vol. ii. 1890); *The Story of the Falkland Islands* (1909), by Sir W. L. Allardye, K.C.M.G. (then governor); Skottsberg's *Wilder of Patagonia* (1911); the *Oxford Survey of the British Empire* (vol. iv. 1914); and Boyson, *The Falkland Islands* (1924). For the naval battle (8th December 1914) see WAR (GREAT).

Fall, the name applied in theology to the change of state with respect to sin which befell Adam and Eve in Eden. Various versions of the story, and the allegorical and other spiritualised explanations that have been offered by theologians, are already discussed under ADAM; here it only remains to point out the special use made of it in the orthodox Augustinian and Calvinistic scheme of theology. The Fall was due to an external temptation offered by the devil, and the inheritance of sin and a corrupted nature descended through the first sinners to all their natural descendants, to whom the guilt of the first sin was imputed in what is called *original sin*. This was possible, because Adam, as the covenant head or federal representative of the whole human race, necessarily involved all mankind—his descendants—in the consequences of his breach of the *covenant* which God made with him at his creation. Christ is 'the second man' and 'the new Adam' (Rom. v. and 1 Cor. xv.), and in the new covenant made with God the believer, through Christ's merits imputed to himself, is freed from the consequences of the Fall in so far as the after-life is concerned. See ADAM, EVIL, and SIN.

Falla, MANUEL DE, Spanish composer and pianist, born 23d November 1877 at Cadiz, studied there and at Madrid, lived for a time in Paris, afterwards in Spain. Leader of the modern Spanish school, he excels especially in orchestral music and in such operas as *Le Vida Breve*, *El Amor Brujo*,

The Three-cornered Hat, The Puppet-show of Mr Peter (1921).

Fallacy, the incorrect performance of the process of reasoning so as to lead to error. The science of Logic reduces sound reasoning to certain rules, and when any of these rules is violated a logical fallacy is the result. The time-honoured division was into two classes, according as the error lay in the *form* of the reasoning or in the *matter*: the formal were entitled *in dictione*, or those appearing in the expression; the material were entitled *extra dictionem*, implying that the fault could not be detected from the language, but must be sought in a consideration of the meaning or subject-matter. Mill proposed to classify all fallacies under (1) Fallacies of Simple Inspection, or Fallacies *a priori*, which includes the whole of what may be termed Natural Prejudices; (2) Fallacies of Observation; (3) Fallacies of Generalisation, including Induction; (4) Fallacies of Ratiocination or Syllogism; and (5) Fallacies of Confusion, comprehending the *petitio principii*, the *ignoratio elenchi*, and ambiguous language generally. Other classifications have been more or less elaborately carried out. But, owing to the enormous variety and intricacy of inaccurate and confused modes of thought, it is difficult to draw up a scheme at once complete and rigorously scientific. See the articles LOGIC, INDUCTION, SYLLOGISM; for Bacon's *idōla*, prejudices influencing the judgment, see BACON; and for the subject of fallacies generally, see the text-books of logic, as those of Whately, Mill, Jevons, and Fowler.

Fallersleben. See HOFFMANN, AUGUST.

Fallières, ARMAND, French President (1906-13), was born at Agen in 1841, and became an advocate, deputy, premier (1883), and president of the senate, 1899-1906.

Falling Bodies. See GRAVITATION, KINEMATICS, ATTWOOD'S MACHINE.

Falling Sickness. See EPILEPSY.

Fallmerayer, JACOB PHILIPP, a German traveller and historian, was born 10th December 1790, at Tschötsch, near Brixen, in the Tyrol. At the university of Landshut he studied law, history, and philology, and in 1826 was appointed to its chair of History and Philology. In 1831-34 he accompanied the Russian general, Count Ostermann-Tolstoi, in a journey through Egypt, Palestine, Syria, Cyprus, Rhodes, Greece, Turkey, and Italy, and twice afterwards (in 1840 and 1847) he revisited the East. The events of 1848 recalled him to Bavaria, and for a short time he sat as a deputy in the Frankfurt parliament. Fallmerayer spoke a great number of European and oriental tongues. He died at Munich on 26th April 1861. His principal works are *Geschichte des Kaiserthums Trapezunt* (1827), *Geschichte der Halbinsel Morea im Mittelalter* (2 vols. 1830-36), and *Fragmente aus dem Orient* (2 vols. 1845). His views on the Slavonic origin of the modern Greeks excited the liveliest controversy at the time of their publication (1835). His complete works, with a Life, were edited by Thomas (3 vols. Leip. 1861).

Fallopius, GABRIEL, Italian anatomist, born at or near Modena in 1523. He was professor of Anatomy in 1543 at Pisa, and in 1551 at Padua, where he died, 9th October 1562. He devoted special attention to the anatomy of bones, and wrote careful descriptions of the ethmoid and sphenoid bones, and of the internal ear. The canal which transmits the facial nerve after it leaves the nerve of hearing is still known as the aqueduct of Fallopius. In myology he corrected various errors

into which Vesalius had fallen. He also studied the organs of generation in both sexes; and the Fallopian tube which connects each ovary with the uterus (see OVARIOTOMY, WOMB) is named after him. He was superintendent of the Botanical Garden at Padua, and had a reputation as a botanist. A complete edition of his works in four folio volumes was published in 1600.

Falloux, FREDERIC ALFRED PIERRE, COMTE DE, a French author and statesman, was born at Angers, 7th May 1811. He first drew attention to himself by two works penetrated by an ardent love of the old Bourbon order of things—*L'Histoire de Louis XVI.* (1840) and *L'Histoire de Saint Pie V.* (1844). In 1846 he was chosen deputy for the department Maine-et-Loire. In religion he advocated the ideas of Montalembert, in politics those of Berryer, and united with his Legitimist sentiments a love of liberty and education strangely incongruous with the historic character of his party. After the revolution of February 1848 he exhibited much energy as a member of the Constituent Assembly, was one of those who organised the resistance to the insurrection of the 15th May, and, as reporter on the national workshops, pronounced for their immediate dissolution. He was also one of the most ardent promoters of the expedition to Rome. On the election of Louis Napoleon to the presidency, Falloux was appointed Minister of Public Instruction, an office which he held for only ten months. After the *coup d'état* he retired from public life to a country-seat near Angers, where he occupied himself with agricultural pursuits, and where he died, 6th January 1886. He was a member of the French Academy. His writings include *Souvenirs de Charité* (1857), *Méditations et Prières* (1863), and *Le Convention du 15 Septembre* (1864).

Fallow (from the same root as Ger. *fahl* or *faß*, expressing a pale dun, tawny colour). This word sometimes signifies waste, untilled land; but usually it is applied to land that is ploughed and otherwise cultivated for a season without being cropped. The most of the wheat raised by the Romans was sown after the land was fallowed; indeed, the usual rotation was fallow and wheat alternately. It was only fertile soils that could long support such an exhausting system; hence resulted the decreasing produce which the later Roman agricultural authors so often speak of and lament.

The fallowing of land was introduced into all the countries which fell under the dominion of the Romans. Britain during their sway soon exported large quantities of wheat, and for centuries after the Romans left no other mode of cultivating the land was followed. It may here be observed that, wherever the system of fallowing without giving manure to the crops is practised, it necessarily supposes that the soil is at least moderately fertile. This system is most successful on argillaceous soils, which are retentive of organic manure, and which cannot be cleaned by any other method. The destruction of weeds, such as couch-grass (*Triticum repens*) with its long jointed root-stocks, is the first great object of fallowing. The exposure of the soil-substance to the weathering action of the air and the rest given to the land are minor objects. The loss from washing out of valuable soluble substances, more especially nitrogen, by rain, is a serious disadvantage of fallowing; and this, along with the possibility of the land becoming more and more foul with weeds during a wet summer, makes the benefits of the practice extremely doubtful, unless under exceptional circumstances.

It was long before fallowing was introduced to any extent in Scotland; but about the beginning of the 19th century it was largely practised.

Owing, however, to the draining of the soil and the extension of the green-cropping system, it is now confined to the most retentive clay-soils, where it affords the only means of thoroughly cleaning the land. Sometimes as many as three or four ploughings are given in summer before the seed is sown in autumn. In old cultivated countries land is commonly so much reduced in its organic matter that fallows require to be dressed with farm-yard or other organic manure, in order to yield satisfactory crops. Since the general introduction of green crops the term fallow has departed in some measure from its original meaning. These crops are sown on what was formerly the fallow break, and are now often styled fallow-crops. The land, no doubt, receives in some measure a fallowing; it is freed from weeds, and allowed to rest from the growth of grain crops. Bastard-fallowing is a term which is used in Britain when hay-stubble is ploughed up in the end of summer, freed from weeds, and sown with wheat in autumn.

Where arable cultivation is carried on in semi-arid regions (dry farming), the land is commonly fallowed in alternate years. The object in this case is to enable the land to accumulate moisture, surface tillage being carried out repeatedly in order to prevent evaporation. Under this system, and with other devices for the conservation of moisture, good crops can be grown every second year where the annual rainfall is as low as 12 or 14 inches.

Fallow-chat. See WHEATEAR.

Fallow-deer (*Cervus dama*), a native of the Mediterranean districts of Europe and Asia, whence it has spread or been introduced into other countries, such as Britain, where it leads a vigorous semi-

Fallow Deer (*Cervus dama*).

domesticated life in many parks. Some authorities refer its introduction into Britain to the Romans; others point to fossilised remains and regard it as indigenous. It may have been exterminated and subsequently reinstated more than once. It is a very graceful animal, standing about 3 feet high at the shoulders, coming in stature between the Roe-deer (q.v.) and the Red Deer (q.v.). The usual summer colour is reddish-brown with white spots, while in winter the spots are fewer and the general shade grayer. A quite unspotted type also occurs, and white or other sports or varieties are common. The tail is black above, white below. The antlers, confined as usual to the bucks, or males, are cylindrical at the base, give off two tines at some distance apart, and then form a shovel-like or palmate expansion. The young male of the first year has no antlers, and the increasing annual development is marked for six years. Fawn, pricket, sorrel, soare, buck of the first head, and

buck complete are the names used to distinguish the various grades. The eyes and ears are large, and under the former there lie conspicuous sub-orbital cavities, which are wholly glandular, and not 'breathing places,' as Gilbert White and others have supposed. The breeding season is in October, and the doe bears in June. There is generally a single fawn, though occasionally two. The fallow-deer seem naturally timid and gentle, and become readily accustomed to man. The flesh is much esteemed. See DEER; Lydekker, *British Mammals*; Sir Harry Johnston, *British Mammals*, Millais, *British Deer*.

Fall River, a busy manufacturing city and port of entry of Bristol county, Massachusetts, at the mouth of the Taunton River, 51 miles S. of Boston by rail. The town, founded in 1803, and incorporated in 1854, is well built, the handsome city hall, Durfee High School, Bradford Durfee Textile School, and many other buildings being largely constructed of a fine granite quarried in the vicinity. It has a splendid harbour, and is connected with New York daily by steamboat. Fall River is the largest cotton manufacturing city in the United States, and has also large print works and bleacheries. Other manufactures are thread, yarn, hats, &c. The city has an excellent water-supply. Pop. (1870) 26,766; (1890) 74,398; (1911) 119,295; (1920) 120,485.

Falls. See WATERFALLS.

Falmouth, a municipal (formerly parliamentary) borough and seaport of Cornwall, on the southern side of the estuary of the Fal, 18 miles NNE. of the Lizard, and 66 by rail WSW. of Plymouth. It chiefly consists of a narrow street, a mile long, with suburban terraces and villas on the heights behind; and it has a marine drive, several pleasure-grounds, a library, a polytechnic society (1833), and a town-hall (1866). The harbour, one of the best in England, is 5 miles long by 1 to 2 miles wide, and 12 to 18 fathoms deep. The entrance is defended on the west by Pendennis Castle (c. 1538-44), which crowns a rock 198 feet high, and which in 1646 surrendered to Fairfax after a five months' siege; on the east, by St Mawes Castle (1543). Pop. of the municipal borough (1851) 4953; (1891) 4273; (1921, as extended in 1892) 13,318. The parliamentary borough, including Penryn, was merged in the county in 1918. From 1688 to 1850 Falmouth was one of the principal packet-stations for foreign mails. There is much ship-repairing and building, and a considerable pilchard-fishery off the neighbouring coasts. Here orange and lemon trees yield plenty of fruit on open garden-walls. Falmouth has arisen since 1613, Sir Walter Raleigh having drawn notice to its capabilities. Charles II. incorporated it in 1661; and at one time it was a stronghold of Quakerism.

False Acacia. See ROBINIA.

False Bay. See CAPE OF GOOD HOPE.

False Decretals. See CANON LAW.

False Pretences. See FRAUD. For False Money, see COINING; for False Swearing, see PERJURY; and for False Weights, see WEIGHTS.

False Point, a cape and harbour of Orissa, 43 miles E. of Cuttack by canal. The harbour, which has a lighthouse, is safe and roomy, and is considered the best between Calcutta and Bombay; it is the entrepôt for the trade of Orissa, and a regular port of call for steamers.

Falsetto, a term in singing for the highest register of a man's voice, which joins the natural or chest-voice, and which, by practice, may be so blended with the chest-voice as to make no perceptible break. See VOICE.

Falstaff. See OLDCASTLE, and FASTOLF.

Falster, a Danish island in the Baltic, south of Zealand, which measures 26 miles by 16 at its widest part, and has an area of 183 sq. miles. It is flat, remarkably fruitful, and well cultivated. Its inhabitants employ themselves chiefly in agriculture and cattle-breeding.

Falun, or **FÄHLUN** (called also *Gamla Kopparberget*—i.e. 'the old copper-mine'), a town of Sweden, 50 miles W. of Gävle. It has for more than six centuries been famous for its copper-mines, though the quantity of ore now obtained is much smaller than formerly. The excavations extend for miles underground. Destroyed by fire in 1761, Falun was rebuilt on a regular plan; but its wooden houses have a sombre appearance, being blackened by the fumes of the numerous smelting-furnaces. Pop. 13,000.

Faluns, a term given by the agriculturists of Touraine to shelly sand and marl, which they use as manure, and applied by geologists to the deposits from which they are obtained.

Fama (Gr. *Phēmē*), the goddess of rumour, a personification which appears in the works of the earliest poets. Sophocles makes her the child of Hope; Virgil, the youngest daughter of Terra, and sister of Enceladus and Cæus.

Fama Clamosa, in the ecclesiastical law of Scotland, is a widespread and prevailing report imputing immoral conduct to a minister, probationer, or elder of the church. When such report exists, a presbytery may commence process against a minister without the instance of any particular accuser, but as acting for the vindication of their own order, and in behalf of the morals of the community. If satisfied that the *fama* is not groundless, the presbytery serves the offender with a libel when no private party comes forward to execute it.

Famagosta, or **FAMAGUSTA**, a seaport on the east coast of Cyprus, on the supposed site of ancient Arsinoë. It was a place of importance during the Crusades; and under the Venetians from 1487 to 1571 it became a rich and flourishing seaport, with 30,000 inhabitants. On falling into the hands of the Turks after a long siege (1571), it began to decay; an earthquake in 1735 completed its ruin. The church of St Nicholas is a fine specimen of mediæval architecture; in it Richard I. of England crowned Guy de Lusignan king of Cyprus in 1191. Famagosta, which has only some 6000 inhabitants, possesses a natural harbour, 1½ mile long by ½ mile wide, improved in the 20th century. The chief exports are corn and its famous pomegranates.

Familiar (Lat., 'servant'), a supernatural being in attendance upon a magician, wizard, or other professor of the black art. The belief in spirits as especial patrons or guardians of individuals is very ancient, and is still widely spread among more than savage races. The guardian angel is indeed an integral part of his faith to many a Christian, as much as the *torngak* to the Eskimo, or the *genius natalis* to the ancient Roman. The genial and sportive guardian spirit of the household is also a venerable belief, and we find in Leviticus (xix. 31) a warning against familiar demons who give occult knowledge. During the middle ages the belief in 'enchanted rings' containing familiar spirits was widely diffused throughout Europe, the magicians of Salamanca and Toledo being especially famous for their skill in thus subjugating and imprisoning demons. The notion of familiar spirits is one perfectly natural to the Persians and Hindus, and Aladdin's 'slave of the lamp' is an example in point. A favourite form assumed by the familiar spirit in western Europe was that of a black dog. Such was the case with the famous Cornelius

Agrippa, who was always accompanied by a devil in the shape of a black dog. When he saw that his death was at hand, according to Paulus Jovius, he took from the dog's neck a collar inscribed with magic symbols, and let him go with the words: *Abi, perditâ Bestia quæ me totum perdidisti*. Butler, in his *Hudibras*, gives the dog the respectable office of tutor to the sage, and Wierus, the pupil of Agrippa, assures us that the animal was no cacodæmon but a natural pet. At least there is no doubt about the black dog in Goethe's *Faust* and his association with Mephistopheles, and there is good tradition that Simon Magus also had a familiar in the same form. See **DEMONOLOGY** and **WITCH-CRAFT**.

Familiars. See **INQUISITION**.

Familistère. See **GUISE**.

Family (from Lat. *familia*, formerly identified with Oscan *famel*, slave, now connected with Sans. *dha*, to settle), in the restricted sense, the group formed by a man, his wife, and his children, but also in Roman law, and in the practice of primitive peoples, including household slaves. In a more extended sense, family is or was used to mean those descended from a common ancestor, the kindred (cf. Roman *jus civile*) or all those connected by blood on the male or female side (*jus gentium*), or even the *gens*, the agnatic descent of which was a matter of belief only.

By *natural family* is meant the group of descendants of an ancestor still alive; when the eldest ascendant is supreme in this household, we get the *patriarchal family*. The *joint* or *extended family*, also called *house community*, is an association of many living in a common dwelling and governed by a common chief, often the oldest male; from the joint family may be developed the *village community*. The joint family is the important social unit in Indian law; it is also found in West Africa, though the comparative absence of property and the undeveloped condition of law make it less important.

The patriarchal family played an important part in the discussion, based on very limited knowledge of the relevant facts, which raged round the theories of Maine, Morgan, McLennan, and others in the latter half of the 19th century. Maine (*Dissertations on Early Law and Custom*, 1883, p. 199) held that all early societies that had any permanence or solidity were or claimed to be descended from a common ancestor. This theory will hardly hold good of primitive peoples known to us at the present day, even if we note that Maine has dropped from his definition the element of the supremacy of the oldest male, which is an essential feature of the patriarchal family. It is clear that the pretence of common descent may well be an *ex post facto* explanation of the unity of the society, which was in fact due to quite other causes.

Generally speaking, the first historians of human society regarded the facts at their disposal from a crude evolutionary standpoint, which attempted to conceive of all human societies as so many stages on a single line of progression. Morgan, for example, postulated, first, a stage of promiscuity; second, the intermarriage of brothers and sisters (consanguine family); third, polygamy (Punaluan family), in which either the males or the females were blood or tribal brothers and sisters. Out of this developed temporary marriage (the pairing family), the patriarchal family (conceived by him as polygynous), and monogamy. He held that from the Punaluan family developed the Turanian system of kinship, under the influence of promiscuity regulated by totemic exogamy. Our present European system arose in place of, though not out of, the Turanian.

It has now been shown (*Tylor Essays*, 1907, p. 309) that the Hawaiian system (Punaluan family), which Morgan put at the base of his whole system, inasmuch as the consanguine family was a purely hypothetical stage, is not only a relatively late stage, but was in vogue mainly if not entirely among the chiefs. Our available knowledge provides not one shred of testimony—either from social facts or from the philological evidence of the classificatory system of kinship—that promiscuity was the earliest stage or at any time a ruling principle of human society. Customs of avoidance between brother and sister, on which Morgan laid much stress as evidence of a stage of promiscuity, are probably late developments.

It is a little difficult for the present generation to understand the causes which led to the vehement controversy between Morgan and McLennan, who differed mainly in their interpretation of classificatory terms of relationship, and in the details only of their scheme of evolution of society. Both postulated primitive promiscuity, from which, according to McLennan, owing to infanticide causing scarcity of women, was evolved first Nair and then Tibetan polyandry, involving kinship (i.e. the reckoning of descent) through women. This led, through marriage by capture, to exogamy and the loss of homogeneity in groups. Neither infanticide, polyandry, nor capture had the importance which McLennan attached to them, and his explanation of the origin of exogamy is quite unconvincing. He supposed that women, being scarce, were valuable (obviously as wives), and would not be allowed to leave their own group (though the ordinary custom of exchange of sisters satisfies the conditions). Many men were, however, compelled to look for wives outside their own group, and eventually their own women ceased to be regarded as possible wives, and were in the end forbidden as spouses to men of their own group.

It is certain that the exogamous social group has developed in many parts of the world from the family, and that the rule of exogamy is an extension of the rule against incest between kin, the origin of which is uncertain.

The tendency of modern research is to work out the history of society for each cultural area. Dr Rivers showed for Melanesia (*History of Melanesian Society*, 1914) that terms of relationship will give us a clue to social institutions, especially forms of marriage, which have left no other trace.

Unless the Melanesian facts are deceptive, it is certain that the history of society has been a far more complicated process than the earlier theorists recognised. Dr Rivers supposed that the family (in the restricted sense) was the starting-point of the evolution of society in Melanesia. With the development of the dual system (see TOTEMISM) the classificatory system came into use. At a later period, owing possibly to the intrusion of a new race which brought few women with it, sexual communism took the place of individual marriage, but this communism was a state of regulated promiscuity, inasmuch as society was divided into two groups, and men of one group had relations only with women of the other group.

Sexual jealousy began to play an important part later, especially in the case of the old men, who attained a position of dominance; and old men monopolised the young women of the community, taking them as individual wives. Such communistic relations as continued were limited to those between men and women of the same generation. Old men were in the habit of handing over one or more wives to their sister's sons or to their son's sons (in this connection it should be noted that a marriage between a man and his daughter's daughter or his brother's daughter's daughter was

known; the grandfather's wife was not, therefore, necessarily old), in order to satisfy their desire for individual wives. As, under a dual organisation, the father's sister is also the mother's brother's wife, we find also a custom of marrying the father's sister. At a later period the mother's brother handed over his daughter instead of his wife to his sister's son, and thus gave rise to the very important form of union to which the name 'cross-cousin' marriage is given. Normally, the cousins who marry are the children of own, not tribal, brother and sister. At this time originated also marriage by capture. A man appears to have given his daughter not only to his sister's son, but also to his younger brother; hence a widow may not marry the elder brother of her husband. More especially in the Banks Islands there is a widespread custom of adoption of children. Dr Rivers gave reasons for supposing that this is due to the state of sexual communism, which gave rise to a community of children. It seems probable that the customs of adoption are due in large measure to an increasing recognition of the bond between father and child.

The data for studying the history of social evolution in other parts of the world are at present lacking. The Melanesian results are largely based on the study of kinship and systems of relationship, the close dependence of which on forms of marriage has been amply demonstrated. Generally speaking, the history of marriage in Melanesia has been from a (hypothetical) stage where it was regulated by kinship to a stage in which phratry or clan exogamy laid down the prohibited degrees. The pendulum is now swinging back, or has already swung back, to regulation of marriage by kinship. It is not improbable that this general sketch will be found to be true of other large areas.

It has been shown elsewhere (see TOTEMISM) that the rule of descent, by which is meant solely the regulation of the membership of the social unit (i.e. moiety, clan, or caste) may be either matrilineal (following the female line), or patrilineal; we have now less reason to believe that the former rule is earlier (cf. Graebner, *Methode der Ethnologie*, 1911, p. 90; Rivers, *Melanesian Society*, ii. 568). The rule of descent may depend on the kind of marriage.

Among aberrant forms of the family must be mentioned the *pirrauru* custom of the Australian Dieri, who also recognised, like the Melanesians, the marriage with the brother's granddaughter. The facts are not absolutely established, but it appears that a woman, after contracting an individual marriage, was united in a secondary union (cicisbeism) with one, usually several, men. In like manner a man was united in *pirrauru* with several women. But, as in Tibetan polyandry, all children were reckoned the offspring of the primary husband. The institution is probably due to the scarcity of women caused by the dominance of the old men. It has often been quoted as an example of 'group marriage,' but this term cannot correctly be applied to it.

In recent years American observers have maintained the priority in time of the so-called 'loose' organisation. This is not exactly a form of descent, for in it kinship is recognised through both parents, an impossibility when the meaning of 'descent' is the 'rule by which membership of a social group is determined.'

It must not be supposed that matrilineal descent, which regulates marriage, implies the supremacy of women, for among primitive peoples the authority of the husband over the wife is independent of descent (Malinowski, *Family*, 77). Nor yet does it exclude the recognition of the kinship of father

(or mother) and child (Thomas, *Kinship and Marriage*, p. 23). Inheritance of property and succession to chieftainship are equally independent of the mode of descent (Rivers, *Melanesian Society*, ii. 319), though it is certain that in some matrilineal societies, at any rate, the sister's son is a man's natural heir.

Some authors (*Jour. R. Anthropol. Inst.*, xviii. 245-89) have laid much stress on the importance of matrilocal (formerly called *beena*) marriage, in which a man goes to live with his wife's family. Closely related to this is bilocal marriage, in which the husband takes his wife to his own kin after remaining a longer or shorter time with her family; the classical instance is the case of Jacob, who served seven years for his wives. Patrilocal marriage (termed *ba'al* marriage by Robertson Smith) appears to be the normal type.

On the whole, customs of residence are less important in their influence on the family than the method by which the wife is obtained. Where she becomes one of her husband's family, usually by purchase, the children naturally belong to the husband, independently of the rule of residence; where she remains a member of her own kin, the children are members of her kin, whether she resides with her husband or not. In parts of West Africa two forms of marriage exist side by side; the purchased ('bond') wife's children alone can succeed to property, and the 'free' wife's children remove at the husband's death to their mother's town. If a free wife or her children die, the husband may not bury them, but must hand them over to the mother's family for interment. It is, however, possible for the father's family to purchase such children, who can then succeed their father as chief, or inherit his property.

Generally speaking, even among peoples who do not recognise the free wife as a normal type, a woman's children belong to her family until the bride-price is paid, or their claims are satisfied in some other way; and a wife repudiated without cause can also, in some parts of West Africa, claim her children, and take them with her to her family.

Conversely, after payment of bride-price, the paternity of a woman's children is often a matter of indifference. The husband may claim children born before wedlock (provided he is the first to pay bride-price), or after his wife has quitted him (provided his purchase-money is not refunded). Children begotten by a brother after the first husband's death are frequently accounted those of the original husband (Levirate), and, exceptionally, the children begotten by a stranger belong to the same category.

In some parts of West Africa the wife is free, with her husband's consent, to cohabit with any one, and in other parts she quits her husband after a few months of wedlock, and practises free love till she is pregnant.

This free recognition of children, regardless of paternity, makes it clear that purchase, i.e. *potestas*, is the important element. The position of a household slave, who occupies a place hardly, if at all, differing from that of a child, bears out this view.

Fosterage may set up a relationship closely akin to that of the actual children of a man, and adoption is also of much importance; it is either penal, to replace a murdered member of the family; or voluntary, by purchase or simple declaration.

Ancestor worship is a further important element; it maintains the unity of the joint family, and gives cohesion to groups varying in composition from the individual family, recruited as has just been shown, to the exogamic social unit, where the ancestor may replace the totem as the sign of common origin, real or assumed. It sometimes happens that worship of ancestors in the female

line is also kept up; and in this case there is *prima facie* reason to suppose that kinship was originally reckoned through females.

In other respects, also, a child stands in close relation to its mother's family, not only as regards marriage prohibition, but also in respect of property; in West Africa, if there is a lack of land in the father's family, the normal resource is to apply to the mother's relatives for an allotment.

The law of inheritance has a deep influence on the form of the family. Family property may remain undivided (joint family) after the death of the male head in whose hands it is concentrated; or it may be equally divided among the sons (gavel-kind), sometimes with a larger share to the eldest, or to both eldest and youngest; or it may pass to the eldest son, or the eldest sons of each of the wives (in polygyny), or to the youngest son (Borough English). The importance of these modes of distribution lies especially in the fact that the heir to property may also be heir to children, and therefore not only receives the bride-price of unmarried daughters, but is the head of all males of the family.

It seems clear that there has been a tendency to pass from a condition in which matrilineal descent and inheritance are recognised to one of which patrilineal descent is the rule. The simple reason is that there is a closer bond between a father and his own children than with his sister's, and the change was simplified by the fact that wife-purchase put the wife, and therefore by analogy the children, in a man's power. Rights of succession (to chieftainship, &c.) usually pass in the male line, and the rise of chieftainship must have been another powerful lever in forwarding the change to agnation (patrilineal descent or kinship). It must not, however, be supposed that inheritance and succession are necessarily in the male line. In the case of the Iroquois tribe, titles, rights, and property were transmitted in the female line, though a man's own brothers as well as his sisters' children were possible heirs. Woman owned the lodge and all within it, the clan burying-ground and all other lands, and her own children; she had the right to select from her sons the candidates for clan and tribal chieftainship, and to initiate proceedings for their deposition; she alone could adopt aliens into her group, and a man could adopt an alien as a kinsman only with the tacit or expressed consent of the matron of his clan; a mother could forbid her sons to go on the warpath; a woman received prisoners of war as spoils, with liberty to kill them or replace slain kinsmen by them; she might demand from her husband's clansmen a captive or a scalp to replace a loss in her family. The representatives of women formed the clan, tribal, and other councils; there were chieftainesses who levied contributions for ceremonials and assemblies, and they guarded the treasure of the tribe, consisting of wampum, feather-work, &c.; a woman might even be made regent when the ordinary male chieftom was vacant. The penalties for killing a woman were double those for killing a man. To this state of things the name matriarchy can properly be applied.

The term matriarchy has often been applied to the institution of matrilineal descent, and it has been maintained on insufficient grounds that this alone tends to elevate the social status of women. Generally speaking, woman among primitive peoples enjoys a larger measure of independence and authority in agricultural communities, in which she is, at least to some extent, the provider. But even in Australia the old women occupied an important position in certain tribes.

See KIN, MARRIAGE; also ANCESTORS (WORSHIP OF), TOTEMISM.

Family, in biological classification, means an alliance of nearly related genera. Individual, species, genus, family, order, class, and phylum are the common categories of classification in ascending order, with intermediate ranks, such as sub-genus, sub-order, sub-family, section, and sub-phylum. Thus, the dolphin family—*Delphinidae*—includes the genera *Delphinus* or *Dolphin*, *Monodon* or *Narwhal*, *Delphinapterus* or *Beluga*, *Phocaena* or *Porpoise*, *Orca* or *Grampus*, &c., and is itself included in the order *Cetacea*, in the class *Mammalia*, in the phylum *Vertebrata*. See **GENUS**, **SPECIES**, **TAXONOMY**, **ZOOLOGY**.

Family Compact, the name given to certain political leagues entered into by the Bourbon kings of Europe. Of these, two deserve mention. The first, an agreement concluded between the kings of France and Spain in 1733, was aimed on the one hand against the ascendancy of Austria in Italy and on the other against the mercantile supremacy of Britain on the sea. Out of this arose a war between Britain and Spain in 1739. The second compact, signed in 1761, had for its object the union, in a close offensive and defensive alliance, of the Bourbon sovereigns of France, Spain, and the two Italian kingdoms Naples and Sicily, and Parma and Piacenza; and next year Britain declared war.

Family of Love, or **FAMILISTS**, or **DAVIDISTS**, a sect which appeared in Holland in the middle of the 16th century. It was founded by David Joris or George (1501-56), an Anabaptist of Delft, who left the Anabaptists about 1538, and founded the new communion, while apparently conforming to the Reformed Church (see **ANABAPTISTS**). In the reign of Edward VI., according to Fuller, Henry Nicholas, a disciple of Joris, came over to England, and commenced the perversion of silly people in a secret way. By 1572 they had apparently increased in numbers considerably, for in that year one John Rogers published a work against the *Horrible Secte of Grosse and Wicked Heretiques naming themselves the Family of Love*. In 1580 Queen Elizabeth issued a proclamation for the hunting out and punishing of this 'damnable sect.' The Family of Love, 'or Lust rather,' as old Fuller has it, tried in vain to insinuate themselves into the good graces of King James, and the society gradually disappeared in the 17th century. They disregarded dogma and church ceremonies, and insisted that religion consisted simply in love, which makes us one with God—a doctrine that led to extreme Antinomianism (q.v.).

Famines, or times during which there is a scarcity, more or less severe, more or less local, of food-supplies, are due to a variety of causes. They have been perhaps oftenest caused by drought or deficiency of rainfall, especially in tropical regions; by excess of rainfall, giving origin to floods and inundations, more particularly in northern climes; by excessive frosts and other irregular incidences of climatic conditions; by the ravages of insects (flies, locusts, ants, grasshoppers, &c.) and vermin (rats, mice, &c.); by the devastations of war; and by the wholesale destruction of forests, especially on hillsides, giving rise to drought—a cause which has operated more particularly in northern China. Apart from these causes, the occurrence of famine in a particular locality depends upon the ratio between the population and the food-supply for the time being of that district, or, more correctly, between the amount and extent of the failure in the supplies and the density of the local population. Amongst the factors which exert an injurious effect upon the food-supply must be mentioned not only backward and inadequate methods of agriculture, but sometimes also the

system of agriculture in vogue; deficient means of communication and transport; misappropriation of the soil—i.e. using it for growing crops which add nothing to the food-supply when the land that is devoted to the production of the necessities of life is inadequate for the normal wants of the population; legislative interference, either preventing the free exploitation and development of the complete resources of the soil, or throwing obstacles in the way of the natural distribution of food-supplies; the ill-regulated distribution of food-supplies apart from governmental interference; sudden immigrations of large bodies of people into districts of confined area; the social customs and agricultural habits of a people making them principally dependent upon one kind of food, as the Irish upon the potato; the religious belief of a people restricting them to certain prescribed kinds of food; lack of foresight and energy in the administrative authorities, provincial, national, or general, as the case may be, together with the limited extent and inaccessibility of the resources they have at their command; insufficient resources and powers of organisation of private merchants; undue facilities for commercial speculation in grain and other necessities of subsistence; and the misapplication of grain, &c.—i.e. the using of it in undue quantity for brewing or distilling, and the like. Attempts have also been made to trace some law of relation between the occurrence of famines, more particularly in India, and the sun-spot cycle, the links of connection being the meteorological effects that are supposed to manifest themselves on our planet in dependence upon the cyclical phases of the waxing and waning of the sun's spots.

Famines cannot be wholly prevented. The powerful climatic causes to which they are principally due cannot be controlled by human agency, except to an extremely small degree, chiefly by the maintenance of river-banks and sea-banks, and by the regulation of the forests. The local conditions are in every case so diverse, and often so complicated, that it is fruitless to attempt to give more than a few general rules. In cases where the country is dependent upon irrigation for its fertility, it should be the first care of the inhabitants, or, failing them, of the government, to make provision for the storing of water, to regulate its distribution, and to utilise it in the most economical ways. But the most efficient methods of rendering governmental assistance are to improve the means of transport, to encourage more scientific systems of agriculture, to give warning to districts that are likely to be affected of the threatened approach of a period of scarcity, and then to leave the rest to the enterprise of private merchants. There should be no legislative restrictions on the free transmission of food-supplies from centres of abundance to districts which are suffering from famine. The systems of agriculture best calculated to prevent the occurrence of famines and counteract their devastating effects are perhaps those in which the quantity of land in each farm is large enough to allow of a sufficient variety of crops being produced year by year, so that the cultivator need not be dependent upon the success of one single crop for his sustenance, or even his livelihood. In India each province is required to maintain a famine fund.

The appended list includes a few of the more important famines of the world, either from their historical significance or from the great destruction of life that attended them. A much more detailed list, together with a couple of excellent papers on the subject, by C. Walford, will be found in the *Journal of the Statistical Society* (1878-79).

879 A.D.	Universal famine.	1711.	Carniola; lasted several years
1005	England	1769-70.	India; three million people perished.
1016	Throughout Europe	1781-83.	In Carnatic and Madras.
1022.	In many parts of the world.	1782-84.	India.
1051.	Mexico.	1790-91.	India.
1052-60.	In Ghor, India.	1822.	Ireland.
1064-72.	Seven years' famine in Egypt.	1846-47.	Ireland; potato famine.
1069.	In north of England.	1866	Bengal; one million and a half died.
1162.	Universal famine.	1877	India.
1314.	Silesia, Poland, and Lithuania.	1877-78.	North China.
1344-45.	India, especially in the Deccan.	1885-89.	North China.
1347.	Italy.	1891-92	Russia.
1491.	Ireland.	1897.	India.
1586-89.	Ireland.	1899-1900.	India.
1600.	Russia.	1905	Russia.
1631	India, Asia generally.		

A widespread famine followed the Great War in Europe, especially Russia. It was after a famine in 1586 that the poor-law in England had its beginning. Famines have been unhappily frequent in India, as in 1889, 1892, 1897, and 1899-1900 (Romesh-Dutt, *Open Letters*, 1900).

Fan, an implement for creating a current of air, generally with the view of cooling the person. The term comes from the Latin *vannus*, the broad, shallow basket into which corn and chaff from thrashing were received to be tossed in the air so that the wind might carry away the chaff. The ordinary fan may consist of any light, flat, expanded surface set in rapid reciprocating motion by the hand; but for many mechanical operations, such as sifting, winnowing, ventilating, and extracting gases, rotating fan-blades are mounted, under such names as Fans, Fanners (q.v.), or Fan-blasts, by which strong and continuous air-currents are raised. The Punkah (q.v.) employed in India for circulating air in apartments is simply an enormous fan.

The common hand-fan, used as a personal accessory, is an implement of great antiquity, which naturally was prized most in regions where the heat was greatest. It is known to have been in use among the ancient Assyrians and Egyptians, and from its frequent representation on early Greek vases it must have been a familiar implement among that people. These ancient fans were sometimes made of very large size, and carried on long shafts or poles by female slaves (*flabelliferæ*), eunuchs, or boys, whose duty was to keep the air in circulation, and to drive away flies from the table or the person. The *flabellum*, or fan to brush away flies from the sacred vessels, was used in the Western Church from the 4th till the 14th century; and gorgeous *flabella* of peacocks' feathers are still borne by the pope's attendants in solemn processions. Similar fans, used to keep flies from settling on the embroidered case of the *torak*, may be seen in Holman Hunt's picture of 'The Finding of Christ in the Temple'; and Mr Butler's *Ancient Coptic Church* contains several pages on the use of the fan in that communion. Among eastern nations generally the fan was an implement of great importance, and large fans—like sunshades, to which they are closely allied—possessed special significance as symbols of authority and emblems of royalty. In Japan, where to this day the fan is an indispensable adjunct of the daily life of all classes, large rich fans are used in ceremonial dances, in which they are accessories of peculiar significance.

Fans are of two kinds, the folding and the non-folding. To the latter class belong all state and ceremonial fans, while those carried about by ladies belong to the folding class. Beyond those distinctions, however, it is impossible to define the material, form, or structure of fans, these, especially in the case of non-folding fans, being endlessly diverse. The folding fan consists of two principal portions, the mount or leaf (Fr. *ferille*) and the stick (*bois*).

The leaf, which forms a segment of a circle, consists of two equal pieces of paper, fine parchment, satin, crape, tulle, or cotton, folded into from twelve to twenty-four equal folds. The stick consists of a number of 'brins' equal to the folds in the leaf, with two stout outer guards (*panaches*). These may consist of wood, ivory, mother-of-pearl, or metal, richly carved, inlaid, or otherwise worked in the case of fine fans, the leaf of which may be elaborately painted. The upper part of the brins is continued by thin, flat strips of wood between the folds of the leaf. The brins with the outer guards are collected and held together at the head or end (*tête*) by a pin passing through them, which forms the pivot on which the fan opens or closes. The folding fan is said to have been a Japanese invention which originated in the 7th century, the idea having been supplied by the wing of the bat. From Japan the invention passed into China; but it was not till about the beginning of the 16th century that such fans began to be used in Europe. They first found their homes in Italy and Spain, but early in the 16th century they came into use in France, and their manufacture was established in Paris, where since that time they have formed the most prominent of the small industries known as *articles de Paris*. In 1673 the *maîtres éventailistes* were formed into a corporation by Louis XIV. French fans of the 18th century became real works of art, on which frequently the ability and taste of the most skilful goldsmiths, jewellers, metal-workers, and carvers were combined with the decorative painting of artists of the foremost position. Fans painted by the 18th-century artists Watteau, Lancret, Pater, Boucher, &c. command very high prices; and such eminent artists of the 19th century as Diaz, Lami, Glaize, Isabey, Jacquemart, &c., devoted their talents to fan-painting. See Uzanne, *The Fan* (trans. 1883); Lady C. Schreiber, *Fans and Fan Leaves* (2 vols. 1888-90); *Éventails* (Par. 1891); Cust, *Fans and Fan Leaves* (Brit. Mus. 1893); Salwey, *Fans of Japan* (1894); G. W. Rhead, *History of the Fan* (1910).

Fanariots, the Greeks inhabiting the Fanar or Fanal quarter of Constantinople appear to have been descendants of such noble Byzantine families as escaped the fury of the Turks, recruited by emigrants from different parts of the old Byzantine empire. They figured in Turkish history principally as diplomats, administrators, and bankers. From 1669 onwards the Dragomans of the Porte were usually chosen from amongst them. From them too were chosen, until the outbreak of the revolution in 1882, the hospodars of Wallachia and Moldavia, while, in addition, the disposal of most of the civil and military posts under the Turkish government was in their hands. In the Greek struggle for freedom (1821-26) the Fanariots displayed no great zeal or activity, but nevertheless were severely punished by the Turks.

Fandango, like the *Bolero*, is an old Spanish national dance, in 3 time. It is danced most gracefully in the south country, usually to the accompaniment of a guitar, while the dancers beat time with castanets. It proceeds gradually from a slow and uniform to the liveliest motion; and, notwithstanding the simplicity of the *pas*, expresses vividly all the gradations of the passion of love. See DANCE.

Faneuil, PETER, a merchant in Boston, U.S., was born of a Huguenot family at New Rochelle, N.Y., in 1700, and died in 1743. His name is remembered from his having built the Faneuil Hall in Boston at his own cost (1742), and presented it to the town. Originally the building contained a hall for public meetings, with lesser apartments above, and a basement used as a market. In 1761 it was

destroyed by fire, and rebuilt. During the revolutionary struggle with England the hall was so often used for important political meetings that it became known as 'the cradle of American liberty.' In 1805 the building was increased in height by an additional story, and also increased in width.

Fanners, a machine employed to winnow grain, driven by hand or by machinery. In passing through the machine the grain is rapidly agitated in a sieve, and as it falls through a strong current of wind, created by a rotatory fan, the chaff is blown out at one end, whilst the cleansed particles fall out at an orifice beneath. The fanners superseded the old and slow process of winnowing, which consisted in throwing up the grain by means of sieves or shovels, while a current of wind, blowing across the thrashing-floor, carried away the chaff. A machine for the winnowing of corn seems for the first time to have been made in Britain by Andrew Rodger, a farmer on the estate of Cavers in Roxburghshire, in the year 1737. Strangely enough, there was a strong opposition to the use of this helpful instrument, the objectors seeing in it an impious evasion of the Divine will. To create an artificial wind was a distinct flying in the face of the text Amos, iv. 13: 'He that formeth the mountains and createth the wind.' See BLOWING-MACHINES.

Fanning, a coral island in the Pacific, lying in 3° 51' N. lat. and 159° 22' W. long. It has about 150 inhabitants, and was formally annexed by Britain in 1888, as on the line of the (already projected) submarine cable between Canada and Australia and New Zealand. Massive mortalless masonry has been found buried under guano. English Harbour is the port. Fanning Island is included in the Gilbert and Ellice Islands Colony. On Fanning Island and on Washington Island (70 miles NW.), which have a heavy rainfall (100 inches or more), coconut-palms are cultivated.

Fano (Lat. *Fanum Fortunæ*, so called from the temple of Fortune commemorating the defeat of Hasdrubal on the Metaurus), a town and seaport of Italy, on the Adriatic, 29 miles NW. of Ancona by rail. Its cathedral of St Fortunato and numerous churches contain paintings by Domenichino, Guido, Guercino, &c.; and there is a triumphal arch of white marble, raised in honour of Augustus. The inhabitants (28,000) carry on considerable trade in corn, oil, and silk goods; but the harbour is now greatly choked up with sand.

Fanø, the northernmost of the North Frisian Islands of Denmark, is a pleasure-resort.

Fan-Palm, a name common to all those palms which have fan-shaped (palmate) leaves, but more particularly applied to *Chamaerops* (q.v.), and in the United States to the Palmetto. The Talipot Palm (*Corypha umbraculifera*) is also called the Great Fan Palm. For the Ethiopian Fan Palm, see DELEB PALM.

Fans, a race of aborigines, but apparently not true Negroes, in western equatorial Africa, between the Gabun and the Ogowe rivers, first accurately described by Du Chaillu. They are a fine race of savages, but are avowedly cannibals.

Fanshawe, SIR RICHARD, was born at Ware Park, Hertfordshire, in 1608, studied at Jesus College, Cambridge, and afterwards entered the Inner Temple, but found law distasteful, and went abroad to study languages. On the outbreak of the Civil War he took part with the king, and while with him at Oxford met and married in 1644 the lively and brave Anne Harrison (born 1625), with whom he lived in the most complete happiness throughout life. In 1648 he became treasurer to the navy under Prince Rupert, in 1651 was taken prisoner at the battle of Worcester, and on Cromwell's death withdrew to the Con-

tinent. After the Restoration he was appointed ambassador at the courts of Portugal and Spain, but was superseded by Lord Sandwich early in 1666, and before his return died suddenly at Madrid on the 26th June of the same year. His devoted wife carried his body to England for burial in Ware church, had much difficulty in recovering but a part of her husband's arrears of salary and money expended in the king's service, and survived till 1680. Fanshawe's works include *The Faithfull Shepherd* (1647), a translation from the Italian of Guarini; *Selected Parts of Horace* (1652); and *The Lusiad, or Portugal's Historicall Poem* (1655), a translation from Camoens. Lady Fanshawe wrote charming *Memoirs* (ed. H. C. Fanshawe, 1907).

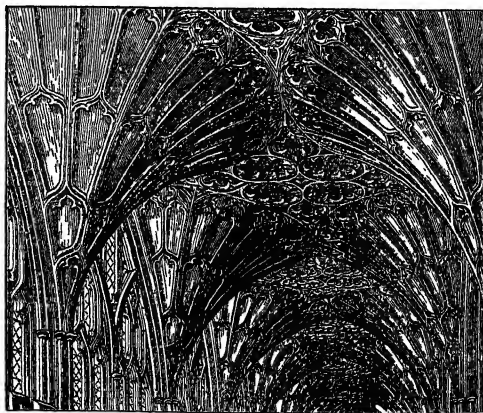

Fantasia is, like Capriccio, a title given to an instrumental composition whose form cannot be classified under any of the recognised species, but is a product of the individual fancy of the composer. In the music of the 17th and 18th centuries it was applied to pieces containing imitative passages, similar to the vocal madrigal; and hence the 'working-out' section in the sonata form obtained the name of 'free fantasia.' The later fantasia is, however, usually a pot-pourri—a medley of favourite airs, with intermediate 'brilliant' passages—a species of effusion to which unfortunately an impetus was given by pianists of the rank of Thalberg and Liszt.

Fantin-Latour, IGNACE HENRI JEAN THÉODORE (1836–1904), painter and lithographer, was born at Grenoble. His portrait groups and his flower studies are most noteworthy. See Life by Jullien (1909).

Fantis, a Negro people on the Gold Coast, belonging to the same stem as their Ashanti (q.v.) neighbours, but possessing a greater muscular development. They were once the most powerful race in that part of Africa, but early in the 19th century were subjugated by the Ashantis, and since the Ashanti wars have come completely under British rule. In the war of 1873–74 they proved cowardly and worthless allies.

Fantoccini. See PUPPET.

Fan-tracery vaulting, a kind of Late Gothic vaulting (15th and 16th centuries), so called from its resemblance to a fan. The ribs or veins spring from one point, the cap of the vaulting shaft,

Fan-tracery:

From the Cloisters, Gloucester Cathedral.

and radiate with the same curvature, and at equal intervals, round the surface of an inverted curved cone or polygon, till they reach the semicircular or polygonal ribs which bound the upper part of the cone and divide the roof horizontally at the

ridge level into diamond and other patterns. The spaces between the ribs are filled with foils and cusps, resembling the tracery of a Gothic window; hence the name *fan-tracery*. The spaces between the outlines of the fans at the ridge level are called by Professor Whewell (*German Churches*) ridge lozenges. In Henry VII.'s Chapel, Westminster, one of the best examples of this kind of vaulting, these lozenges are occupied by pendants, which produce a very astonishing effect, looking like arches resting on nothing. They are, however, supported with great ingenuity by internal arches, rising high above the visible vaulting. This arrangement is one of those *tours-de-force* which astonish the vulgar, but are only adopted when art has reached a low level and has in a great measure given place to artifice. Fan-tracery is a very beautiful kind of vaulting, and is peculiar to England, where it originated, and where alone it was practised. Among the finest examples are St George's Chapel, Windsor, and King's College Chapel, Cambridge. Fan-tracery is also frequently used in the vaulting of cloisters, as at Gloucester, Canterbury, and Chester.

Farad (from Faraday), the name of the practical unit of electrical capacity, first given by the British Association Committee on Electrical Standards in 1863, and authorised by the International Electrical Congress held in Paris in 1884. Under **ELECTRICITY** will be found the definitions of the ampère, the volt, and the ohm, which are respectively the practical units of current, potential, and resistance. The Coulomb is the name given to the unit of quantity, and is the quantity of electricity transferred by a current of one ampère in one second; and then the farad is defined as the capacity of a conductor which when raised to a potential of one volt has a charge of one coulomb. The farad is, however, an inconveniently large quantity, so that it is customary to measure capacities in *microfarads*, the microfarad being the millionth part of a farad. See also **MAGNETISM**.

FARADAY, MICHAEL, one of the most distinguished chemists and natural philosophers of the 19th century, was born, a blacksmith's son, at Newington Butts, near London, 22d September 1791. At thirteen he was apprenticed to a bookbinder; yet even then he devoted his leisure hours to science, and made experiments with an electrical machine of his own construction. Chance having procured him admission, in 1812, to the chemical lectures of Sir H. Davy, the latter engaged him as his assistant at the Royal Institution. He travelled to the Continent with Davy, as his assistant and amanuensis. On their return to London Davy confided to Faraday the performance of certain experiments, which led in his hands to the condensation of gases into liquids by pressure. In 1827 he succeeded to Davy's chair of Chemistry in the Royal Institution. He was created D.C.L. in 1832.

In chemistry his treatise on *Chemical Manipulation* (1827; 2d ed. 1842) is even now a very valuable book of reference. As discoveries or investigations of a high order in this branch of science we may mention new compounds of chlorine and carbon (1821); alloys of steel (1822); compounds of hydrogen and carbon (1825); action of sulphuric acid on naphthaline (1826); decomposition of hydrocarbons by expansion (1827); and the very valuable series of experiments, made in 1829-30, on the manufacture of glass for optical purposes, which resulted in one of his greatest discoveries, to be afterwards mentioned.

As practical applications of science his suggestions as to the preparation of the lungs for diving and the ventilation of lighthouse lamps are conspicuous, as are also his celebrated letter on table-turning and his lecture on mental education.

To enumerate only the most prominent of his publications on physical science, we may commence with the condensation of the gases (already referred to); then we have limits of vaporisation, optical deceptions, acoustical figures, re-gelation, relation of gold and other metals to light, and conservation of force. Of these the condensation of gases into liquids and solids, though in some cases previously effected by others (and Faraday was ever the foremost to acknowledge another's priority), he really made his own, not only by the extent and accuracy of his experiments, but by the exquisite experimental methods by which he obtained the results. His ideas on re-gelation and its connection with the motion of glaciers have not met with universal acceptance, though (see **HEAT**, **ICE**, **GLACIER**) there is no dispute as to his being correct in his *facts*. In regard to conservation of force, he seems to have been misled by the incorrect use of the word Force (q.v.), for in his article on the subject he describes experiments made with the view of proving the conservation of force proper; whereas the doctrine of conservation asserts merely the conservation of 'energy,' which is *not* in any sense force. He *may* be right also; but, if so, it will be by a new discovery having no connection whatever with 'conservation of energy.'

His Christmas lectures at the Royal Institution, though professedly addressed to the young, contain much that may well be pondered by the old. His manner, his unvarying success in illustration, and his felicitous choice of expression, though the subjects were often of the most abstruse nature, were such as to charm and attract all classes of hearers. Besides his *Lectures on the Non-metallic Elements* and *Lectures on the Chemical History of a Candle*, we have his *Various Forces in Nature*, a simple work, but in reality most profound, even in its slightest remarks.

But the great work of his life is the series of *Experimental Researches on Electricity*, published in the *Philosophical Transactions* during forty years and more. Fully to understand all the discoveries contained in that extraordinary set of papers would require a knowledge of all that has been discovered during that time as to electricity, magnetism, electro-magnetism, and diamagnetism. We may merely mention the following, almost all of which are discoveries of the *first* importance. They are given in the order of publication, which is nearly that of discovery: (1) Induced electricity (1831), comprehending and explaining a vast variety of phenomena, some of which have already been applied in practice (especially as magneto-electricity) to lighthouses, electro-plating, firing of mines, telegraphy, and medical purposes—electric currents derived from the earth's magnetism; (2) the electrotonic state of matter (1831); (3) identity of electricity from different sources (1833); (4) equivalents in electro-chemical decomposition (1834); (5) electrostatic induction—specific inductive capacity (1838); (6) relation of electric and magnetic forces (1838); (7) the electricity of the Gymnotus (1839); (8) hydro-electricity (1843); (9) magnetic rotatory polarisation (1846), effected by means of the optical glass already mentioned; (10) diamagnetism and the magnetic condition of all matter (1846); (11) polarity of diamagnetics, and the relation of diamagnetism to crystalline forms (1849); (12) relation of gravity to electricity (1851)—this, as before remarked, is Faraday's attempt to prove a conservation of force proper; (13) atmospheric magnetism (1851), an attempt to explain the diurnal changes of the earth's magnetic force by the solar effect on the oxygen of the air, a very interesting paper. Faraday's work is not only of extreme importance in itself, but it

has been of the utmost consequence to science by leading Clerk-Maxwell to his wonderful investigations of the dynamics of the electro-magnetic field and the electro-magnetic theory of light, and preparing the way for the great advance in physics in the 20th century.

Faraday, who had received a pension in 1835, was in 1858 given a house in Hampton Court. In 1862 he delivered his last discourse on 'gas-furnaces,' and advocated the use of magneto-electric light in lighthouses. In 1865 he resigned the position of adviser to the Trinity House, also that of director of the laboratory of the Royal Institution. Faraday, who was a devout Christian and a member of the Sandemanians or Glassites, died at Hampton Court, 25th August 1867. See *Life* by Tyndall (1868; 5th ed. 1894), Bence Jones (1870), and J. H. Gladstone (1872); W. Jerrold (1891), and S. P. Thompson (1899).

Faradisation. See ELECTRICITY (MEDICAL).

Farāzī, a sect of reformed Mohammedans in eastern Bengal since the middle of the 19th century. They differ from the orthodox Sunnites (of whom they may be regarded as a branch) in rejecting traditional custom, and in holding that the Koran is the sole and complete guide to spiritual life.

Farce (Ital. *farsa*, from Lat. *farcire*, 'to stuff'), a dramatic piece of a broad comic character. The difference between it and comedy proper is one of degree and not of kind. The aim of both is to excite mirth; but, while the latter does so by a comparatively faithful adherence to nature and truth, the former assumes to itself a much greater license, and does not scruple to make use of any extravagance or improbability that may serve its purpose. It does not therefore exhibit, in general, a refined wit or humour, but contents itself with grotesque rencontres and dialogues provocative of run and jollity. The beginnings of Greek and Roman comedy consist of rustic farces or pantomimes (see ATELLANÆ); the first farces, in the modern sense, were composed by the fraternity of the Bazoche (q.v.) in Paris, as a contrast to the ecclesiastical plays performed by the religious orders. The most widely celebrated and most important of early farces is that of the advocate *Maistre Pierre Patelin*, which was acted in the 15th century, and quickly spread itself over Italy and Germany. It is full of genuine comic quality, and its dialogue has brightness and reality. Subsequently Molière elevated and refined the farce into his wonderful series of comedies of character. In England the origin of the modern farce dates from about the commencement of the 18th century. Of all the numerous farces which have been performed before English audiences only those of Samuel Foote, who reverted, however, to the abuse of personal mimicry which characterised the earliest farces, have kept a place in literature. See DRAMA.

Farcy. See GLANDERS.

Fardel-bound. See CONSTIPATION.

Far Eastern Republic, in south-eastern Siberia, coincided roughly with the old Transbaikalian, Amur, and Maritime provinces, with Chita for its capital. It extended from Lake Baikal to the Seas of Okhotsk and of Japan, and included north Sakhalin. This region, inhabited mainly by Russians, with some Buriats and others, was, after the fall of the tsardom, a theatre of military operations for Czechs, Russian 'Whites' under Koltchak, Cossacks under Semenov, Japanese and other foreign troops, against whom the peasantry gradually made headway. In its difficult position between the Japanese and the Bolsheviks, the country, under the influence of Alexander Krasnotchekov, adopted a democratic constitution (1920), recognised by Russia, and set up a coalition

government. The expulsion of the 'White' government from Vladivostok in October 1922, and the evacuation of the town by the Japanese, removed obstacles to union, and in December the republic joined the Soviet Republic as an autonomous region. Area, 675,000 sq. m.; pop. 2,000,000.

Fareham, a market-town and watering-place of Hampshire, on a creek at the north-west end of Portsmouth harbour, 12 miles SE. of Southampton and 9 NW. of Portsmouth. It has earthenware, sackcloth, and rope manufactures. The population has increased from 3450 in 1851 to about 10,000.

Farel, GUILLAUME, one of the most active promoters of the Reformation in Switzerland, was born in 1489 at Gap, in Dauphiné. He studied at Paris, and was at first distinguished by his extravagant zeal for the practices of the Catholic Church; but, moved to the study of the Scriptures, he was converted to Protestantism, and, being by nature vehement even to indiscretion, he immediately commenced to proselytise. The chief scene of his labours was France and Switzerland. At Basel, in 1524, he opened his career of controversy and evangelisation by publicly sustaining thirty theses on the points in dispute between Roman Catholicism and Protestantism. He subsequently preached at Strasburg, at Montbéliard, and at Neuchâtel. In 1532 he went to Geneva, but soon had to leave the city. He returned in 1533, was again compelled to withdraw, but once more entered it in 1534; and in 1535 the town-council of Geneva formally proclaimed the Reformation. Farel, however, was a missionary, not a legislator, and the organisation of the Genevan Church passed into the hands of Calvin (q.v.). The severity of the new ecclesiastical discipline produced a reaction, and in 1538 the two Reformers were expelled from the city. Farel took up his residence at Neuchâtel. In 1557, along with Beza, he was sent to the Protestant princes of Germany, to implore their aid for the Waldenses, and on his return sought a new sphere of evangelistic labour in the Jura Mountains. When trembling upon three-score-and-ten, he married a young wife. In 1560 he proceeded to his native Dauphiné, and passed several months preaching against Catholicism; and in November 1561 he was thrown into prison for a time. He died at Neuchâtel on the 13th September 1565. His works were mainly polemical.

Farewell, CAPE, the southern extremity of Greenland, lying in 59° 44' N. lat. and 43° 54' W. long., consists of a rocky hill, nearly 1000 feet high, situated on an island off the coast. It is generally beset with ice, which appears to come from the north-east and to sweep round into Davis Strait. Hence the cape is but little known; and, in fact, the Danish traders and seamen generally round it at more than 100 miles' distance.

Fargo, capital of Cass county, North Dakota, on the Red River of the North, 234 miles W. of Duluth by rail. From an insignificant village in 1874 it has become the financial and commercial centre of the state, with flour and other manufactures and a Congregational college and state agricultural college. Pop. 22,000.

Fargus, FREDERICK. See CONWAY (HUGH).

Faria y Sousa, MANUEL DE, Portuguese historian and poet, was born near Pombeiro in 1590, was secretary to his kinsman the Bishop of Oporto, and became in 1631 secretary to the Spanish embassy at Rome, where he enjoyed the favour of Pope Urban VIII. Three years later he returned to Spain, and died at Madrid in 1649. His writings fill more than sixty volumes, partly in Spanish, and comprise works on Portuguese history, on Portugal and its possessions in America and Africa, and commentaries on

Camoens. His Portuguese poems comprise about two hundred good sonnets and twelve eclogues, and it is mainly by these, and also by three theoretical treatises on poetry, that he has influenced the development of the poetic literature of Portugal, in which he was long regarded as an oracle. His poetry exhibits talent and spirit, but is on the whole tasteless and bombastic.—He must not be confounded with Manuel Severin de Faria (1583–1655), who was one of the most learned numismatists of his age.

Faribault, capital of Rice county, Minnesota, on the Cannon River, 53 miles S. of St Paul, with a state institution for the deaf, dumb, and blind, and the Seabury divinity school. It has manufactures of flour, woollens, furniture, &c. Pop. 11,000.

Faridkot, one of the Sikh cis-Sutlej states, south-east of Firozpur (area, 642 sq. m.; pop. 130,000). It is ruled by a raja, resident in the town of Faridkot (pop. 12,000), 60 miles SSE. of Lahore.

Faridpur, chief town of a district of the same name in the delta of the Ganges, 110 miles NE. of Calcutta; pop. 13,000.

Farina, a Latin term for meal or flour, is also applied to many substances which agree with the meal of the corn-plants or Cerealia in containing much starch.—*Fossil farina*, *mountain milk*, or *Agric mineral*, is a deposit of silicified animalcules, obtained from China, &c.

Farina, J. M. See EAU DE COLOGNE.

Farinelli, the name under which the Neapolitan *castrato* (see EUNUCH) Carlo Broschi (1705–82) became famous for his marvellously powerful and flexible soprano voice in Rome (where he made his debut in his seventeenth year), in Vienna, and in London (in 1734; see PORPORA, HANDEL); and in Madrid, where he settled in 1737, he was not merely adored as an opera-singer by the court and the populace, but was made a royal favourite and, consulted by the king on all matters of state, was lavishly pensioned, knighted, and made a grandee of Spain. Ferdinand VI. founded an opera-house according to his suggestions and made him director. In 1761 he retired, enormously rich, to a country house near Bologna, where he lived and died respected for his character.

Farington, JOSEPH (1747–1821), born a vicar's son at Leigh, was known only as an R.A. potentate and landscape artist till the discovery of his diary (ed. James Greig, 1922 *et seq.*) from 1793 to the day of his death (by falling downstairs in church), full of vivid jottings on great men and events.

Farini, LUIGI CARLO, born in 1812 at Russi, in the province of Ravenna, studied medicine at Bologna, and practised with success in his native city, but in 1841 had to leave the Papal States. The amnesty and liberalism of Pius IX. attracted him to Rome in 1846, where he held office under Rossi. Called to Piedmont, in 1851 he became minister of Public Instruction, in 1859 provisional governor of Modena, in 1861 minister of Commerce in the last cabinet of Cavour, and he was himself premier from December 1862 till the breakdown of his health in the following March. A strenuous labourer in the cause of a united Italy, he died near Genoa on 1st August 1866; and in 1878 his remains were translated to Russi. Among Farini's works may be mentioned *Il Stato Romano*, translated into English under Mr Gladstone's supervision (4 vols. 1851–54), and *Storia d'Italia*, a continuation of Botta's celebrated work.

Farm (O.E. *feorm*; Low Lat. *firma*, from Lat. *firmus*, 'durable'), the term usually employed to denote a piece of land, either pasture or arable, held in lease by a tenant from the proprietor; but of course the term farmer is often applied

to a person who owns as well as cultivates land. In America the farmer usually owns the land he cultivates. In this work the history and present position of agriculture, agricultural statistics, and the division of land are dealt with under the head AGRICULTURE; and other matters relevant to farming (such as cattle, dairy, landlord and tenant, lease) are treated under the various heads cited at the end of that article.

FARM BUILDINGS.—The buildings of a well-appointed farm in Great Britain consist of a residence for the farmer and his family, cottages for the farm-labourers, and the farm-steading. The dwelling-house varies to some extent with the size and character of the holding, the 'rules of the estate,' the fashion of the district, and the taste and social standing of the tenant. Modern farm dwelling-houses upon holdings of about 200 acres and upwards are, as a rule, both commodious and comfortable, substantial in construction if not ornate in external appearance, usually surrounded by simply but tastefully laid out grounds, with a moderately sized garden—for, despite the old adage, farmers are not now all bad gardeners. The dwelling-house should be from 50 to 200 yards distant from the steading, and, if possible, upon a slightly higher level, and so situated that from the farmer's parlour and bedroom windows the whole of the steading and stack-yard may be in view.

The servants' cottages should be near the steading, perhaps at the opposite side from the farmer's dwelling-house. The cottages should be plain, substantial, and roomy; they are often in one continuous row, often in pairs, seldom built singly. Each family may have three or four compartments, with a separate door, and a separate plot of ground for garden produce. Cottages for farm-servants are now more fully provided than prior to 1870; and it is well known that, where there is ample cottage accommodation, the supply of agricultural labour is, as a rule, both abundant and of good quality.

The *farm-steading*, as the term is understood in its narrowest and most generally accepted sense, consists of erections provided for the accommodation of the crops, stock, and farm implements and machines. The cost, character, and capacity of the farm-steading vary not only with the extent of the holding, the system of farming pursued, and the situation of the farm in regard to climate, but also to no small extent with the tastes and desires of the land-owner, and perhaps likewise, although to a smaller extent, with the fancies of the tenant. It is the presumption that all the buildings and other permanent equipments of the farm are provided by and are the property of the owner of the soil. The character of the steading is therefore, as a rule, determined by the 'rules of the estate.' These estate rules too often enforce the observance of certain plans irrespective of the exceptional necessities and peculiarities of individual farms. On this account, and through a widespread ambition on the part of both landlords and tenants for imposing and almost luxurious farm buildings—an ambition fostered by, if not born of, the times of exceptional prosperity experienced prior to 1875—an excessive and unreasonable amount of capital has in many cases been sunk in the buildings of the farm, thus placing upon the land a burden which it is ill able to bear, and which is therefore detrimental alike to the land-owner and to the tenant. The greatest amount of steading accommodation is required upon mixed husbandry farms, where a large quantity of home-grown produce is consumed by cattle in winter. Unfortunately upon such a farm the maximum expenditure is required where the land is, as a rule, least able to bear

heavy burdens—viz. in the cold northern districts, where substantial and comfortable houses have to be provided for the stock during the long and severe winters. In many instances there is four or five times as much money sunk in buildings—i.e. apart from the dwelling-houses—upon mixed husbandry farms in the north of Scotland as upon similar farms in the south of England.

The farm-steading is usually situated as near as possible to the centre of the holding, on a dry, airy, yet well-sheltered elevation, with the water-supply abundant, if such is to be had on the farm, but not in close proximity to stagnant water or swampy ground. The open part of the steading should, as a rule, have a southern exposure, yet the immediate situation as to shelter may warrant variations from this rule. The most common and convenient plan for a farm-steading is in the form of three sides of a square or parallelogram, with a wing down the centre, and perhaps also stretching out a short distance at the back of the cross wing, the dimensions of the square or parallelogram being so regulated as to provide the required capacity in the various compartments. Modern experience has fully demonstrated the advantages of covered courts for cattle. In most improved steadings, therefore, the whole or greater part of the spaces between the centre and side wings is roofed and arranged as courts for cattle. The whole of the season's dung is often accommodated in these courts, and is benefited by the treading of the cattle, while the roof saves it from damage by washing with rain-water. Where good management prevails, the liquid manure is collected in a tank close to these courts, and periodically pumped over the heap of solid manure. Quantities of gypsum are sprinkled over liquid manure wherever it is exposed, to fix free ammonia, which would otherwise volatilise and pass away in the atmosphere.

A point worthy of careful consideration is the placing of the various compartments of the steading in such relation to each other that there may be no unnecessary moving of food, manure, or dairy produce, so that time in performing the various operations going on in the steading may as far as possible be economised. The straw-barn should be near the centre of the steading, and the classes of stock receiving most straw accommodated nearest to the straw-barn. The root-stores should be easily accessible from the cattle compartments, the hay-store from the stable, the dairy from the cow-house, and the stack-yard from the threshing-mill and straw-barn. The cart and implement sheds should be near to the stable.

In close steadings most careful attention should be given to *ventilation*, so as to secure a sufficient current overhead to keep the atmosphere pure and equable without allowing draughts to play directly upon the animals. Besides stone and bricks, concrete—1 part of stale Portland cement to 6 parts of broken stones or pure gravel (free from earthy matter)—is now largely employed in the construction of farm buildings, notably servants' cottages. Galvanised corrugated sheet-iron is extensively used in roofing courts for cattle. Covered stack-yards have not come into use, as was at one time expected, but large hay-barns, roofed with corrugated iron, are now very common, and are a valuable acquisition to farm-steadings.

On the American continent farm buildings are generally constructed of wood. It is common there to find all the compartments of the farm-steading grouped under one roof, which is often of great dimensions.

Farmer, JOHN, English madrigalist, born probably about 1565, was appointed organist of Christ Church Cathedral, Dublin, in 1595, deserted and in 1597 resumed his post, and in 1598 was presented

to the vicarage of Kilsheelan, to which, not being in orders, he appointed a deputy. He went to London in 1599, and died there in 1605. His *First Set of English Madrigals* appeared in 1599, his treatise, *Divers and Sundry Ways of Two Parts in One*, in 1591. He contributed to East's *Whole Book of Psalms* (1592) and Morley's *Triumphs of Oriana* (1601). See Fellowes, *English Madrigal Composers* (1921), and for his music, *English Madrigal School* (vol. viii. 1914).

Farmer, RICHARD, D.D., a well-known 18th-century scholar, was born at Leicester, August 28, 1735, and in 1753 was entered a pensioner of Emmanuel College, Cambridge, where four years later he graduated a senior optime. Appointed classical tutor of his college, he took orders, and served the curacy of Swavesey, a village 9 miles from Cambridge. On Dr Johnson's visit to Cambridge the two scholars had a 'joyous meeting,' and ever after kept up the most friendly relations. Dr Farmer became a member of the famous Literary Club, and helped Johnson with Cambridge notes for his *Lives of the Poets*. He soon abandoned his projected history of Leicester, and published in 1787 his only work, the once famous *Essay on the Learning of Shakespeare*, which showed that the great dramatist derived his knowledge of the ancients from translations, having often preserved the phraseology and even the errors of the translators. In 1775 Farmer was elected to the mastership of Emmanuel College, and in 1778 became chief-librarian to the university. In 1780 he obtained a prebendal stall at Lichfield, in 1782 at Canterbury, which he exchanged in 1788 for a residentiary prebend in St Paul's. The remaining years of his life he divided betwixt residence in London and at Cambridge, beloved alike by the members of his college and by London men of letters for his geniality and his brilliant talk over a pipe of tobacco and a bottle of port. He was careless of his appearance, an inveterate collector of old books, and habitually indolent—a failing which alone prevented his making a figure in literature. He died September 8, 1797.

Farmers-general (Fr. *fermiers-généraux*) was the name given before the Revolution of 1789 to the members of a privileged association in France, who farmed or leased the public revenues of the nation. This system of tax-gathering became general in France from the year 1546, when Francis I. let out the *gabelle* or salt-tax in this way. The privileges of the position were sold to the highest bidder; but they were largely in the hands of the king's favourites. The powers, rights, and duties of the class were defined by special decrees; but, however severe may have been the fiscal laws against fraud and contraband, it is notorious that shortly before the Revolution abuses of the most flagrant description had demoralised the system and the men. During the Revolution most of these odious tax-gatherers perished on the scaffold, the innocent among them being occasionally confounded with the guilty. Farmers of the revenue were an institution of ancient Rome (see **PUBLICANS**). Tolls on roads and duties of various kinds were at one time farmed also in Great Britain. See **MONOPOLY**.

Farnborough, an urban district on the east border of Hampshire, 32 miles S.W. of London, contains part of the camp of Aldershot (q.v.). Near it is Farnborough Hill, the residence of the Empress Eugénie, with a mausoleum, in which she is buried with her husband and son. Farnborough gave a title to Sir T. Erskine May (q.v.). Pop. (1921) 12,645.

Farne Islands, or the **STAPLES**, a group of seventeen islets and rocks (area, 80 acres), some being visible only at low-tide, two to five miles off

the north-east coast of Northumberland, opposite Bamborough, are an important bird-breeding station, acquired by the National Trust in 1924. On House Island are remains of a Benedictine priory, dedicated to St Cuthbert (q.v.). The passage between the isles is very dangerous in rough weather; and on the group there are two lighthouses. Here the *Forfarshire* was wrecked in 1838 (see DARLING, GRACE); and here, in 1843, the *Pegasus* met the same fate, when sixty persons were drowned.

Farnell, LEWIS RICHARD, born at Salisbury, 10th January 1856, studied at Oxford, Berlin, and Munich, travelled in Greece and Anatolia, and wrote *Cults of the Greek States* (1896), and other works on Greek and comparative religion.

Farnese, the name of an illustrious Italian family, three members of whom occupy a prominent position in history. ALESSANDRO FARNESE was raised to the papal see in 1534 as Paul III. (q.v.). He founded the duchy of Parma and Piacenza.—ALESSANDRO FARNESE (1546–92), son of the second duke, and one of the most skilful generals of his age, first distinguished himself at Lepanto (1571). Afterwards, as governor of the Spanish Netherlands, he captured Antwerp (1585) for Philip II., and compelled Henry IV. of France to raise the siege of Paris (1590).—ELIZABETH FARNESE (1692–1766) became the wife of Philip V. of Spain in 1714, and was a warm supporter of the policy of Alberoni, Philip's minister. See *Life* by E. Armstrong (1892).—The three pieces of antique sculpture (the Farnese Hercules, Flora, and Bull) were removed about 1790 from the Farnese Palace at Rome to the national museum at Naples.

Farnham, a town of Surrey, 38 miles SW. of London by rail, stands on the Wey, embosomed in hop-gardens. The principal feature is the old castle of the bishops of Winchester, first built by Bishop Henry de Blois, King Stephen's brother. Razed by Henry III., and afterwards rebuilt, it was garrisoned by Charles I., and restored in 1684 to its present state by Bishop Morley. A handsome Italian town-hall was built in 1866. Moor Park, the seat of Sir William Temple, with memories of Swift and 'Stella,' is in the vicinity; so, too, are the remains of Waverley Abbey (1128), whose *Annales Waverlienses* suggested to Scott the name of his first romance. The chief trade is in hops, a very fine variety being grown here. Pop. 12,000. Toplady and Cobbett were natives. Aldershot Camp (q.v.) is 3 miles NE. of Farnham.

Farnworth, an urban district of Lancashire, 3 miles by rail SE. of Bolton, with cotton-spinning, coal-mining, machine-making, and chemical manufactures; pop. 28,000.

Faro, the capital of the Portuguese province of Algarve, on the south coast, behind three islands which form a good roadstead. It has considerable exports of fruits, cork, sumach, and fish. Pop. 13,000. Faro was burned by the English in 1596, and partly destroyed by the earthquake of 1755.

Faro, a widely-known game of hazard, played with cards by a 'banker' against an indefinite number of players. It is so called from Pharaoh or Pharaoh, the old name of one of the court cards.

Faroe Islands. See FAEROE ISLANDS.

Farquhar, GEORGE, was born at Londonderry in 1678, and received his education at Trinity College, Dublin, where, although he did not take any degree, he secured among his comrades the reputation of a wit who was a spendthrift of his witticisms. When he left the university he was engaged as an actor at one of the Dublin theatres, but, like most dramatists who have figured on the stage, he proved but an indifferent performer. Playing a part in Dryden's *Indian Emperor*, and forgetting that he wore a sword instead of a foil, he accidentally

wounded a brother-performer, and was so shocked by the occurrence that he at once quitted the boards. Accompanied by the actor Wilks, he proceeded to London, and shortly after received a commission in the regiment commanded by the Earl of Orrery, which was then stationed in Ireland. Urged by Wilks, and perhaps stimulated by the gaiety and leisure of a military life, he in 1698 produced his first comedy, entitled *Love and a Bottle*, which proved a success. Two years afterwards his *Constant Couple* appeared, which met with a brilliant reception, and to which he wrote a sequel, called *Sir Harry Wildair*. In 1703 he produced *The Inconstant*, founded on the *Wild-goose Chase* of Beaumont and Fletcher, a version in which all the coarseness, and none of the poetry, of the elder dramatists is retained. Having married in the same year, he fell into serious pecuniary difficulties, sold his commission, and, struggling with adverse fortune, succumbed. He died of decline in 1707, leaving 'two helpless girls' to the care of his friend Wilks. During his last illness he wrote the best of his plays, *The Beaux' Stratagem*—in six weeks, it is said—and died while its wit and invention were making the town roar. *The Recruiting Officer* had been produced in 1706.

Farquhar is one of the best of our comic dramatists, although Pope called him a 'farce writer'; less brilliant than Congreve, the Smollett, not the Fielding, of the stage, he possesses on the whole more variety and character than any of his contemporaries. With wit in abundance, he had humanity too, and was a tender-hearted, somewhat melancholy man—'very splenetic, and yet very amorous.'

See Ewald's edition (1893); also Archer's of four plays ('Mermaid Series,' 1906); Dr D. Schmid, *George Farquhar, sein Leben und seine Original-Dramen* (1904); Allardyce Nicoll, *Restoration Drama* (1923).

Farr, WILLIAM, born at Kenley, in Shropshire, 30th November 1807, studied medicine at Paris and London, but devoted himself mainly to medical statistics. In 1839 he received an appointment in the Registrar-general's Office in London, where he eventually became superintendent of the statistical department, a post which he held until 1880. He died in London, 14th April 1883. His chief books are *Tables of Lifetimes, Annuities, and Premiums* (1864); *English Reproduction Table* (1880); and *Net Premiums for Insurance against Fatal Accident* (1880). His *Vital Statistics*, a memorial volume, appeared in 1885.

Farragut, DAVID GLASGOW, the greatest of American seamen, was born of Spanish origin, near Knoxville, Tennessee, 5th July 1801. Entering the navy in 1810, he became a lieutenant in 1825, commander in 1841, and captain in 1855. On the outbreak of the civil war he held by the Union, and in 1862 was given the command of the armament of wooden steamers and mortar-boats fitted out for the capture of New Orleans. The approach to the city was defended by two strong forts, a number of Confederate steamers and an ironclad ram, besides chains stretched across the river, whilst sharpshooters and fire-rafts had been prepared to harass the attacking force. After the forts had been shelled for six days and nights without effect, Farragut decided to force the passage in the darkness, and actually carried through all but three of his vessels, in spite of the terrible raking fire poured in as they passed the opening made in the boom. The Confederate fleet was sunk or burned, and, on the 25th April, the last batteries having been silenced, the city was evacuated, and Farragut's men landed. For many months thereafter he was employed on the Mississippi, until in July 1863 the last fort surrendered, and the entire river was open to navigation. In July 1862 he had been commissioned rear-

admiral, and in 1864 he returned to the Gulf, where on 5th August he fought the battle of Mobile Bay, destroying the enemy's gunboats and a powerful ironclad ram; a few days later the forts surrendered, and the port of Mobile was thenceforth closed to blockade-runners. In December he was made vice-admiral, the grade being created for him by congress, as was also the rank of admiral, to which he was raised in 1866. He died at Portsmouth, New Hampshire, 14th August 1870. There is a colossal bronze statue of Farragut in Washington, and another, of heroic size, in New York. See the Life by his son (1879), and by A. T. Mahan (1893).

Farrant, RICHARD, musician, was born about 1530, entered the Chapel Royal, became organist of St George's Chapel in 1564, returned to the Chapel Royal in 1569, whence he retired in 1580, and died in 1585. His name is best known in connection with the anthem, 'Lord, for Thy tender mercies' sake,' and a chant based on it, which, however, seem certainly not to be his. He actually did compose a full morning and evening service, and two anthems which have been printed, with parts, of other services.

Farrar, FREDERIC WILLIAM, D.D., Dean of Canterbury, was born in Bombay, 7th August 1831, and graduated at London University and at Cambridge, where he was fourth classic. Ordained in 1854, he was for many years a master at Harrow, and in 1871-76 head-master of Marlborough College; in 1868 and 1874-75 he was a select preacher before the university of Cambridge, in 1869-73 honorary chaplain to the Queen, and afterwards a chaplain-in-ordinary. He became canon of Westminster and rector of St Margaret's in 1876, and archdeacon in 1883, chaplain to the House of Commons in 1890, and Dean of Canterbury in 1895. His productiveness as an author was equalled only by the remarkable popularity of some of his writings, which include, besides *Eric* (1858) and other stories of school-life, and his earlier works on philology and education, *The Witness of History to Christ* (Hulsean Lectures for 1870); *The Life of Christ* (2 vols. 1874), which passed through twelve editions in as many months; *A Life of St Paul* (2 vols. 1879); *The Early Days of Christianity* (2 vols. 1882); *The History of Interpretation* (Bampton Lectures for 1885); and *The Lives of the Fathers* (1889). *Eternal Hope* (a volume of sermons, 1878) denied the probability of eternal punishment. Other works were *Darkness and Dawn* (1892) and *The Life of Christ in Art* (1894). He was a contributor to a former edition of *Chambers's Encyclopædia*. He died 22d March 1903; see the Life by his son (1904).

Farrer, LORD (Thomas Henry Farrer, 1819-99), was born the son of a London solicitor, and bred at Eton, Balliol, and Lincoln's Inn, and from 1862 till his retirement in 1886 was permanent secretary to the Board of Trade. He was made a baronet in 1883, and a peer in 1893. In *Free Trade versus Fair Trade* (1886), *Studies in Currency*, and other works, he showed himself an uncompromising free trader.

Farrer, REGINALD JOHN (1880-1920), a Yorkshireman, educated at Balliol, cultivated Alpine plants at Ingleborough, collected in western China and elsewhere, and wrote some good books of travel—*On the Eaves of the World* (1917) and *The Rainbow Bridge* (1921)—besides gardening books and plays.

Farrier, a shoer of horses, who formerly also treated their diseases. See HORSESHOEING, VETERINARY MEDICINE. In every British cavalry regiment there is a farrier quartermaster-sergeant (formerly farrier-major), with three farrier-sergeants and four shoeing-smiths, who attend to the shoe-

ing of the horses and their treatment when sick, subject to the veterinary surgeon. They wear as a badge on the sleeve a horseshoe, in wove for the shoeing-smiths, and in gold for the farriers, who rank as sergeants and wear Chevrons (q.v.).

Fars, or FARSISTAN (anciently *Persis*), a province of Persia, bordering on the Persian Gulf, rises from the steep coast in a succession of broad terraces. The coast zone or 'hot country,' the productiveness of which is greatly dependent upon the rainfall, is backed by the 'land of the passes,' behind which comes the 'cold country'; the interior belongs to the Iranian plateau. The mountain chains, lying parallel to the coast, embrace numerous fertile valleys, rich in pasture and vines and fruit-trees. Amongst the mountains are several lakes, the largest Lake Bakhtegan (q.v.). The rivers are small. The climate varies with the different districts. The principal products of the province are fruits, dates, tobacco, cotton, silk, and excellent wine. Area, about 50,000 sq. m. The population, which is sparse, is estimated at 750,000. The capital of Fars is Shiraz; the port, Bushire, on the Persian Gulf.

Farthing (O.E. *feorðing*, from *feorð*, 'fourth'), an English copper coin equivalent in value to the fourth part of a penny. In accordance with representations made to the government by Dean Swift for the improvement of the coinage, certain pattern farthings were struck in the years 1713-14, known as 'Queen Anne's farthings.' Five distinct varieties are known to exist. The value of the pieces, which are not very rare, has been exaggerated; but one sold in 1907 for £40.

Farthingale, or FARDINGALE (Old Fr. *vertugalle*, from Span. *vertugada*, 'a hooped petticoat'). See CRINOLINE.

Farukhabad, a city of the United Provinces of India, near the right bank of the Ganges, 83 miles NW. of Cawnpore. It is a clean and healthy place, with a considerable trade, and a pop. (with Fatehgarh) of 60,000.—The district of Farukhabad belongs to the alluvial plain of the Doab, the soil being for the most part high-lying, sandy, and infertile. Area, 1700 sq. m.; pop. 900,000. The most important crops are potatoes, indigo, and sugar-cane. The capital is Fatehgarh. The ruins of Kanauj, the capital of a powerful Hindu kingdom, still exist within the district.

Fasces were bundles of rods usually made of birch, but sometimes of elm, with an axe (*securis*) projecting from the middle of them, which were carried before the chief magistrates of ancient Rome as symbols of their power over life and limb. They were borne by the lictors, at first before the kings, in the time of the republic before consuls and prætors, and afterwards before the emperors. Their number varied, a consul and a prætor in his province having twelve, a prætor six, but within the city only two. Valerius Publicola introduced a law that within the city the axe should be withdrawn, except in the case of a dictator, who was preceded by twenty-four lictors, bearing as many fasces. Publicola also made the fasces be lowered at the assemblies of the people, as an acknowledgment of their supreme power.

Fascia, in Architecture, a flat space or band between mouldings. See ENTABLATURE.

Fasciation is a form of monstrosity not uncommon in plants. The growing apex loses its usual conical shape and becomes greatly extended in one diameter, so as to produce a broad band-shaped growing-point. This may continue to widen until it has reached many times the normal breadth without any proportional increase in thickness, and often becomes thrown into irregular folds, the leaf

arrangement becoming correspondingly confused. Cases of fascination occur not unfrequently in the ash-tree, the amricula, daisy, and other common plants, and constantly in the cultivated Cockscomb (q.v.). Such growths are with Welsh Gypsies an object of superstitious reverence.

Fascination (Lat. *fascino*, 'I bewitch,' doubtfully akin to Gr. *bashainō*), an interpretation of the fatal influence of some serpents over their destined prey. Kalm and others describe how the rattlesnake fixes a squirrel with its lidless eye, and so far demoralises the victim that it drops into the distended mouth. Le Vaillant describes the convulsions and finally the death of a shriek, paralysed by fear of a serpent at a distance of nearly four feet. Dr Andrew Smith reports that the non-venomous South African tree-snake (*Bucephalus viridis*) gathers quite a circle of victims. Ellis notes the interesting fact that an object pushed between the eye of the snake and a victimised frog broke the spell. In spite of many observations which suggest mesmeric or hypnotic influence, against which there is no strong improbability, most naturalists regard so-called fascination as equivalent to fear. In panic animals may undoubtedly become paralysed or stupid, or lose the usual power of co-ordinating their actions. See EVIL EYE, SNAKES.

Fascinés (from Lat. *fascis*, 'a bundle') are brushwood fagots bound together with wire, yarn, or withes. They are 18 feet long and 9 inches in diameter, used for revetting the steps and steep interior slopes of field-works and for other military purposes, such as roofing magazines, Casemates (q.v.), Blockhouses (q.v.), &c., when timber cannot be procured. A double row covered with earth several feet thick is almost bomb-proof. They also make a very strong stockade, and can be used in bridging operations and road-making. Cut into six-foot lengths, they are often carried by the men of an assaulting column to fill up the ditch of a work or lessen its depth. Five men can make a fascine in an hour.

Fasciola. See FLUKE, TREMATODES.

Fascismo, a movement organised in Italy by Benito Mussolini, who withdrew from the Socialist party and the editorship of the *Avanti* to press for Italian participation in the Great War by means of his own paper, the *Popolo d'Italia*, published in Milan. In 1920, when many factories were in the hands of the workmen, bands of Fascisti (from *fascio*, 'bundle'), taking the *fascés* as their badge and a black shirt as their distinguishing garb, made melodramatic war upon Socialism, by methods ranging from murder to the administration of castor-oil. Their strength was among the army officers, the captains of industry, and the bourgeoisie, especially in central Italy. They called for a policy of militant imperialism and capitalist enterprise. In October 1922 they seized public buildings in many towns, and moved upon Rome. The army was sympathetic. The king refused to sign a decree establishing a state of siege, and invited Mussolini to form a ministry. His government, mainly Fascista, included members of the nationalist, democrat, and popular (Catholic) parties. A new electoral law assigned two-thirds of the seats in the Chamber to the majority party. Corfu was occupied (see IONIAN ISLANDS), and the League of Nations flouted. State enterprises were converted to private ownership; and the crucifix was restored to its place in every school.

Fasher, a province of Dar-fūr (q.v.).

Fashion and Fashionable, terms applied to occupations, pursuits, education, and manners, as well as to most of the luxuries and necessities of modern civilised life, denote an unending series of

changes and modifications which are most marked and most apparent in the department of dress. Such variations of costume were unknown to most nations of the ancient world, and among the Romans only influenced the accessories of the toilet. The unchanging East is as unchanging in its dress as in everything else, and the fashions to which savage tribes uncompromisingly adhere remain unaltered for long periods. In some remote districts of European countries peasants still dress in the costume brought two or three hundred years ago by the local nobility from court, and the smock-frock of the English agricultural labourer is a relic of Saxon times. The natural conservatism of man often throws strong light upon long-forgotten social history, and nowhere more than in the survivals in modern costume. Thus, as Sir E. Tylor points out, there is much to be learnt from so quaintly cut a garment as the modern evening dress-coat. 'The cutting away at the waist had once the reasonable purpose of preventing the coat-skirts from getting in the way in riding, while the pair of useless buttons behind the waist are also relics from the times when such buttons really served the purpose of fastening these skirts behind; the curiously cut collar keeps the now misplaced notches made to allow of its being worn turned up or down; the smart facings represent the old ordinary lining; and the sham cuffs now made with a seam round the wrist are survivals from real cuffs, when the sleeve used to be turned back. Thus, it is seen that the present ceremonial dress coat owes its peculiarities to being descended from the old-fashioned practical coat in which a man rode and worked.' Again, the English clergyman's bands are directly traceable through intermediate stages to the wide collars which everybody wore in Milton's time, the very name of which also survives in our word *bandbox*. And it is said that the modern cylindrical hat is the indirect descendant of the Puritan steeple-crowned hat, carried across the Atlantic by the Pilgrim Fathers, thence again to France, when Benjamin Franklin and the young Republicans were the height of the fashion, and by the French manipulated into the hat which they gave to all the world.

The Romans spread their dress with their civilisation over Europe, and it was gradually modified by the close-fitting garments of the races of the north till the two styles were united in the 5th century; but fashion in its modern sense cannot be said to begin till the 14th century. Then complaints first arise of clothes being cast aside for others of newer shape and cut. It must be remembered that till the 19th century men's clothes were as delicate in colour and as rich in material as women's; Pepys records in his Diary how he had his wife's gowns cut up into waistcoats for himself. The change during the 14th century from close-fitting tunic and hose to long, loose garments trailing on the ground is even more startling than the outcrop of steeple-like headgear which distinguished the ladies of the 15th century.

The sumptuary laws of the 13th, 14th, 15th, 16th, and 17th centuries clearly show that dress was originally a symbol of rank, strictly prescribed for the various classes of society. An early French law complains of each man clothing himself as he pleased, without reference to his rank, so that it was impossible to tell from his dress whether he was a prince, nobleman, citizen, or labourer. In modern days this state of things is fulfilled to the letter, though costume still retains its old significance in the uniforms of the army and navy, of policemen and postmen, in the lawyer's wig and gown, the judge's robe, the bishop's lawn sleeves, and the university student's cap and gown, all of which, as Herbert Spencer remarks, are worn by

people whose office it is to uphold established arrangements in church and state. The railway companies and the Post-office impose a uniform on their employees, the maid-servant (in Britain) wears a cap and apron, and the waiter a black suit, but the only class who at all times voluntarily mark themselves off from other men are the clergy. Political and religious opinions have been at times symbolised by dress, as with the Puritans and Quakers; and instances of such distinguishing marks as the tricolor of France, the white cockade of the Bourbons and

the Stuarts, the blue and green of the factions in the circus of ancient Constantinople, the orange and green of Irish political parties, and the blue and buff of English elections might be multiplied indefinitely. Dress attained its highest point of significance in France during the last half of the 18th century, when it marks unmistakably the various stages of the Revolution. Rousseau's *Emile* and *Nouvelle Héloïse* and Goethe's *Werther* brought sentimentality into fashion; women's hair was dressed in *bandeaux d'amour* or *poufs de sentiment*; and Marie Antoinette and the

1, Flemish (1841); 2, French (1410); 3, German (1530); 4, Spanish (1580); 5, French (1590); 6, 7, Beginning of 17th century.

ladies of her court sought to return to the simplicity of nature by masquerading in the Trianon attired as shepherdesses and milkmaids. The works of Montesquieu and Voltaire had created an admiration for England, and the courtiers of Versailles dressed themselves like English foxhunting squires, while their wives and daughters got themselves up *à l'Anglaise* in coats with cuffs, collars, and facings, beaver-hats, and cravats. As the political turmoil increased, fashionable attire grew more and more

eccentric and multiform, till at last republican institutions triumphed, and the women of France began to clothe themselves as like as possible those of Greece and Rome both in style and scantiness. They discarded costly materials, and shivered through the winter months clad in a few yards of muslin. Men wore a combination of antique and romantic costume invented by the painter David, which was finished off with Hungarian boots. The gorgeous and stately dress of the courts of Louis

8, Louis XIV. and his Queen (1670); 9, (1740); 10, Prussian court-dress (1780); 11, *À la Grecque* (1800); 12, (1804).

XIV. and Louis XV. had disappeared with the old régime. At the present time the fashions for women in all civilised countries are set by Paris; for men, though not so exclusively, by London.

One marked feature of the ever-changing kaleidoscope of fashion is its tendency to revolve in cycles. The widely-distended skirts of the 16th century reappear in the 18th and 19th centuries after periods of straight-falling folds; the piles of false hair, artificial flowers, feathers, and jewelry which reached their greatest height on ladies' heads about 1780 had their modified counterpart in the chi-

gnon; men's netlier garments are by turns skin-tight or loose and full; and the voluminous folds of muslin in which they swathed their necks at the beginning of the 19th century recall in some degree the ruffs of Queen Elizabeth's courtiers. Cycles of alternate luxury and simplicity have also distinguished all ages, though the simplicity of fashion is often more apparent than real. There can be little doubt that fashions change more quickly each decade, a fact due in great measure to increased facilities of communication, while the triumph of

democracy is shown by their universal adoption by all classes. The question cannot but arise whether in this continual variation the most advantageous and artistic costumes for men and women may not at last be found and kept, but the probabilities seem to be against such a conclusion. Lotze in his *Microcosmus* starts the theory that we prolong the consciousness of our personal existence into any foreign body brought into relationship with the surfaces of our own body, so that we feel ourselves grow taller with our high headgear, move with our fluttering laces and ribbons, and derive vigour from the feeling of resistance arising from a tight band or belt. At the same time it is generally allowed that we are more alive to a new sensation than to one which has been long in the field of consciousness, for, from the very fact that it is unusual, our attention is continually directed to it, while a well-known sensation loses its first intensity and the power of directing our thoughts to itself. In order, therefore, that our clothes may yield us the maximum of pleasant feeling which Lotze says we derive from them, they must not be too familiar in shape, colour, and cut—i.e. we must not only have new clothes, but new styles of clothes. But a volume would be required to determine whether this theory satisfactorily accounts for all the changes of fashion.

See Fairholt, *Costume in England* (new ed. 1885), Planché, *Cyclopædia of Costume* (1876-79); Challamel, *History of Fashion in France* (Eng. trans. 1882); Herbert Spencer's *Ceremonial Institutions* (1879); Robida, *Nos Aïeules* (trans. as *Ten Centuries of Toilet*, by Mrs Cashel Hoey, 1892); Georgiana Hill, *A History of English Dress* (1893); and the articles CRINGOLINE, HAT, &c.

Fashoda, renamed KODOK, a Shilluk town, on an island in the White Nile, 60 miles below the mouth of the Sobat. Its occupation by the French for a few months in 1898 aroused hostile feeling in Britain.

Fast (a word common to the Teutonic tongues, which Grimm derives from a root signifying primarily to hold, keep, observe, and hence to restrain one's self; Lat. *jejunium*, Gr. *nēsteia*, Heb. *tsom*) is the word used to express a certain self-imposed restraint with respect to the nourishment of the body. The abstinence enforced may be either partial, when the restriction is confined to certain articles of food, or total, when all sustenance is dispensed with for a specified time. The origin of the custom seems to be coeval with man's first experience of the salutary influence which abstinence exercises on the health, and with his more or less instinctive consciousness of the necessity of retaining the body in due subjection to the soul. By degrees, the self-mortification which it implied raised it into a sacrifice offered to the Deity; it became a religious observance, was surrounded with rites and ceremonies, and finally bore the stamp of a divine law. Climate, the habits of a people, and their creed gave it at different periods different characteristics; but it may be pronounced to have been a recognised institution with all the more civilised nations, especially those of Asia, throughout all historic times. We find it in high estimation among the ancient Persians of Iran. It formed a prominent feature in the ceremonies of the Mysteries of Mithras, and found its way, together with these, over Armenia and Asia Minor, to Palestine, and northward to the wilds of Scythia. The ancient Hindus, in accordance with their primeval view—which they held in common with the Parsees—of heaven and hell, salvation and damnation, of the transmigration of the soul, and of the body as the temporary prison of a fallen spirit, carried fasting to an unnatural excess. Egypt seems to have had few or no compulsory general

fasts; but it is established beyond doubt that for the initiation into the mysteries of Isis and Osiris temporary abstinence was rigorously enforced. (For Buddhist usages, see BUDDHISM.) That Greece observed and gave a high place to occasional fast-days, such as the third day of the festival of the Eleusinian mysteries, and that, for instance, those who came to consult the oracle of Trophonius had to abstain from food for twenty-four hours, is well known. It need hardly be added that the Romans did not omit so important an element of the festivals and ceremonies which they adopted from their neighbours, though with them the periods of fasting were of less frequent recurrence.

As to the Semitic races, although we find the people of Nineveh undergoing occasional fasts, to which even animals were made to conform, yet the Mosaic law set apart one day only in the whole year for the purpose of fasting. The 10th day of the seventh month (Tishri), called 'the Day of Atonement' (Yom Kippur), or, as the holiest of the whole year, 'the Sabbath of Sabbaths,' was ordained for 'the chastening of the *Nephesh*,' which the traditional law explains as meaning the strictest and most rigorous abstinence from all food or drink, as also from washing, anointing, the putting on of sandals, &c., from the sunset of the ninth to the appearance of three stars on the evening of the tenth day. In process of time, five days of compulsory fasting were added, in commemoration of certain days of humiliation and national misfortune—viz. the 17th of the fourth month (Tamus), as the anniversary of the taking of Jerusalem both by Nebuchadnezzar and Titus; the 3d of the seventh month (Tishri), when Ishmael had killed Gedaliah, the Jewish governor appointed by the Babylonians; the 10th of the tenth month (Tebeth), in remembrance of the siege of Nebuchadnezzar; the 13th of the twelfth month (Adar), the fast of Esther, and the day most rigorously kept next to the great Day of Atonement; and the 9th of the fifth month (Ab), the anniversary of the destruction of the first temple by Nebuchadnezzar and of the second by Titus. The community loved to express their penitence for sin, or their grief on the death of great men, by occasional fastings, which were also considered an efficient means of averting the divine wrath, of insuring victory over an enemy, or of bringing down rain from heaven. Besides, fasting was not unfrequently resorted to by those who wished to free their minds from all hindrances to meditation, as in the forty days of Moses (Exod. xxxiv. 28), or the fast of Daniel. In later times, when, after the destruction of the temple, sacrifices had ceased, fasting, as causing a decrease in the flesh and fat of the individual, was considered to be in some degree a substitute for the animal which had formerly been offered up by the priest. From a means to repentance and inward purification, it became an end and a virtue in itself, an abuse, indeed, neither unknown nor undenounced even in the days of the prophets. Many new fasts were superadded from time to time, but they soon fell into oblivion; and over and above the six already mentioned but few entire days are now observed by the orthodox, and these merely of a local character. Fasting, with the Jews, always implies entire abstinence, and lasts, except on the Day of Atonement and the 9th of Ab—when the sunset of the previous evening is the sign for its commencement—from the break of the day to the appearance of the first three stars. Sackcloth and ashes, the garb of the penitent in ancient times, are no longer worn; but the deepest mourning is visibly expressed by many ceremonies in the Jewish synagogues and homes on the 9th of Ab. Several half-days of fasting have also survived. The individual is bound

to celebrate by fasting the anniversary of the death of his parents, his own wedding-day until the performance of the marriage-ceremony, and the birth of his first-born male child (up to its thirteenth year, when the duty falls upon the latter himself), and on the day preceding the Pesach (Pascha), in commemoration of the sparing of the Israelite first-born in Egypt. The Sabbath causes the postponement of any fast—that of the Day of Atonement and the Fast of Esther excepted—which happens to coincide with it; and children—girls up to their twelfth, boys to their thirteenth year—women with child, and the sick are exempted from the observance.

In the time of Christ, fasting, as we have seen, was held in high estimation. The Mondays and Thursdays—the market-days, on which the judges sat, and the law was read in the synagogues—were especially set aside for this purpose by the Pharisees. The Essenes fasted even more frequently. The Sadducees alone took exception to this rite, and were therefore considered ungodly. Christ himself neither approved nor disapproved of the custom, but, as in all matters of ceremony, allowed his disciples, Jews and Gentiles, to act according or contrary to their old habits. He is distinctly against such a *commandment*, and even excuses those who did not fast; his own abstinence from food for forty days was like that of Moses, entirely an individual act. Roman Catholics maintain that all the words of our Lord, which to Protestants appear to discountenance the obligation of fasting, are directed exclusively against the ostentatious and self-reliant fasts of the Pharisees. They even understand the language which he used in condemning the practice of the Pharisee fasters as containing a direct exhortation to his own disciples—not that they should abstain from fasting, but that they should fast with suitable dispositions. They hold, moreover, that in exempting his disciples from fasting he had regard only to the actual time of his own presence among them. It was incongruous, he said, that the children of the marriage should fast as long as the bridegroom was with them; but, he added, 'the days will come when the bridegroom shall be taken away from them, and then shall they fast in those days' (Mark, ii. 20; Matt. ix. 15). Hence they infer that from the time of our Lord's ascension the practice of fasting became obligatory on his disciples, the temporary cause of the exemption hitherto existing having ceased.

During the first centuries of Christianity voluntary fasts were frequent enough; and fasts were considered a befitting preparation for holy acts and feasts, for ordination and baptism. An annual fast generally observed by all from a very early date was that of the forty hours, from Friday afternoon to Sunday morning, during which Christ lay in the sepulchre. But during the first six centuries the difference in the various Christian communities in this matter was very great. The Montanist heretics were especially rigorous in their fasts. Bishops and councils gradually fixed the times and seasons for the whole of Christendom. The forty hours had gradually become forty days, called the *Quadragesima*; and the Council of Orleans in 541 made it binding upon every Christian not to eat any meat during this time, save only on the Sundays. The eighth council at Toledo in the 7th century declared those who ate meat during Lent sinners unworthy to partake in the resurrection. From the 8th century to the 11th, when a gradual reaction set in, the laws of fasting and the punishments awarded to the transgressors became stricter and stricter; interdict and excommunication were among the penalties. By degrees fasts had become so numerous and different in

kind that they were divided into—(1) *Jeiunium generale* (a fast binding for all); (2) *Consuetudinarium* (local fast, &c.); (3) *Penitential* (atonement for all transgressions); (4) *Votivum* (consequent upon a vow); (5) *Voluntare* (for the better carrying out of an undertaking). These, again, were kept as either (1) *Jeiunium naturale* (an entire abstinence from food or drink, especially in preparation for the reception of the Eucharist); (2) *Abstinentia* (certain food only being allowed, but several times a day); (3) *Jeiunium cum abstinentia* (the same food, which must be taken once a day only); or (4) *Jeiunium sine abstinentia* (all kinds of food, but only once a day). The food prohibited on partial fast-days included, during certain periods, not only the flesh of quadrupeds, fowl, and fish, but also the 'lacticia'—i.e. all that comes from quadruped and bird, as butter, eggs, milk, &c.

Fasts gradually developed in the Roman Church into—(1) Weekly fasts, of which Friday, as the day of the crucifixion, seems to have been early and generally observed. To this was added the Wednesday, as the day on which the death of Christ was resolved upon. At a synod in Spain in the beginning of the 4th century the Saturday was superadded; but this innovation met with great opposition, especially in the East. (2) Vigils, originally night-services observed by the first Christians on the eve of Sundays and festivals, partly in imitation of the Jewish custom of celebrating the entrance of the Sabbath and of festivals on the evening of the previous day, and partly from fear of the danger to which a service in the daytime would have exposed the early converts. Although these night-services became unnecessary in the course of time, they were still continued up to the 4th century, when, owing to the abuses to which they led, they were abolished, or rather transformed into fast-days, kept on the eve of great festivals in honour of Christ, the Virgin, Saints, and Apostles. (3) The great or forty days' fast (Quadragesimal fast), the most important and most rigorously enforced of all. The forty hours of fast, in commemoration of the forty hours during which Christ's body lay in the tomb, gradually expanded to forty days, as mentioned before, in pious allusion to the forty days of Moses, Elijah, Christ, the forty years' sojourn in the desert, or the forty camps—all considered typical; and the fasting became severer the nearer Passion-week itself approached, in which many other signs of mourning and contrition were generally exhibited. (4) The Quarter fasts on the Wednesdays, Fridays, and Saturdays in one week of each season, in imitation of the four Jewish fasts in the fourth, fifth, seventh, and tenth months.—There were still many other fasts, such as those of ordination, &c., but these had only a temporary existence, and do not fall to be treated here. Nor can we enter into the various dispensations granted by the church, or the special pastoral letters generally issued before Quadragesima, nor into the variations in the observance of fasts and fasting in our own days; we can only add that they have in a great measure lost their former severity, and that only partial abstinence is the rule in all cases. More must not be taken than one full meal, and that not before mid-day, nor consisting of flesh meat. Besides this a *collation* of about eight ounces of fruit, vegetables, bread, or small fishes may be taken. The modern meaning of this word was originally due to the slight refreshment in the ancient monastic discipline, taken just before the reading of the 'collations'—i.e. conferences (of Cassian) and such other works. In spite of its diminution of the former severity in the practice of fasting, the

opinion of the church held in former days, that fasting is meritorious and conducive to the salvation of the soul, has undergone no change.

In the Greek Church fasting was and is kept with much greater severity, the non-observance of it being the least venial of sins. The days here extend over almost three-quarters of the year. The principal ones are the Wednesdays and Fridays—with a few exceptions—throughout the whole year; the great Easter fast lasting forty-eight days; that of Christmas, thirty-nine days; that in honour of the Virgin, fourteen days; and that of the Apostles, beginning on Monday after Trinity, and extending to the 29th of June. Besides those smaller fasts of preparation, which correspond to the vigils of the Roman Church, they have many more occasional fasts, which we, however, must omit here.

The Church of England considers fasting a praiseworthy but by no means obligatory custom. Hook, in his *Church Dictionary*, explains the distinction between the Protestant and the Roman Catholic view of fasting as consisting in this, that the Roman Catholic regards the use of fasting as an imperative means of grace, the Protestant only as a useful exercise preparatory for the means of grace. In proof how much the Church of England has left the question of fasting to the conscience and discretion of her members, it may be observed that she has neither defined the mode or degree of fasting, nor anywhere given a positive command to fast. The days named by the English Church as seasons of fasting or abstinence are the forty days of Lent (q.v.), including Ash-Wednesday and Good Friday; the Ember (q.v.) days; the three Rogation (q.v.) days; all the Fridays in the year (unless Christmas Day fall on one); and the eves or vigils of certain festivals.

The sacramental *fast-days* so long observed in Scotland are now fallen into disuse. They were already completely discontinued in Glasgow in 1836, and in Edinburgh in 1837. The Scottish fast-day was instituted as a day for 'fasting, humiliation, and prayer,' and always fell upon some day of the week preceding the yearly or half-yearly *Communion Sunday*, or Sunday set apart in the Presbyterian churches for the dispensation of the Lord's Supper. It was observed exactly as a Sunday, with sermons in the churches and the complete cessation of business.

In the United Kingdom, on occasion of wars and public calamities, the sovereign has from time to time appointed by proclamation a day for a solemn national fast, humiliation, and prayer—as on 21st March 1855 (the Crimean war), and 7th October 1857 (the Indian Mutiny).

A few words remain to be said of the Mohammedan fasts. Islam, as an offspring of Judaism and Christianity, adopted this custom with many others from both churches. During the whole month of Ramadan, in which the Prophet brought the Koran from heaven, eating, drinking, smoking, smelling perfumes, &c. are strictly forbidden from daybreak till sunset; for the intervening nights, however, all these restrictions are removed. There are, besides, many voluntary fasts, expiatory like the 10th of Moharram, corresponding to the Jewish Day of Atonement, or for the averting of the divine wrath in sudden calamities, or as an indemnification for the omission of certain pious acts, as the pilgrimage, &c. See JEWS, MOHAMMEDANISM, MONACHISM, ASCETICISM.

Besides the *Bible*, *Schulchan Aruch*, *Koran*, and the Fathers generally, see Bingham, *Origines Ecclesiasticae*, vol. ix. (1708-22); Fabricius, *Bibliogr. Antiquaria*; Muratori, *De Quatuor Temporibus Jejuniorum*, &c.; Siegel, *Altehrthümer*; Walch, *De Jejunio Quadragesimali* (1727); Robert Nelson, *Festivals and Fasts of the Church*; Liesmayr, *Die Entwicklung der Christlichen Fastensitten* (1877); and Thurston, *Lent and Holy Week* (1906).

FASTING.—By this term is meant the deprivation of food—the materials by which loss of matter and energy from the body is made good.

Food-stuffs may be divided into (1) water, (2) solid food-stuffs.

When water is withheld death occurs in the course of a few days. For the protoplasm of the tissues to undergo the chemical changes upon which its vitality depends, a certain proportion of water is essential, and when this is not present death ensues through the cessation of these changes.

It is more especially to the deprivation of *solid food* that the term *Fasting* is applied. The physiology of this condition has been most carefully studied in dogs, cats, and other of the lower animals, while one or two observations have also been accomplished in cases of voluntary fasts in man.

To understand the condition, it must be remembered that the energy required in the body is under normal conditions supplied by the various organic food-stuffs, which, entering the body in the condition of large and complex chemical molecules, are oxidised and excreted as simpler bodies, and by their disintegration yield energy (see the article METABOLISM). During fasting it is by the disintegration of the tissues of the body that the necessary energy is yielded. This energy is required not only for the production of mechanical work done by the body, but also for the production of heat, so that the temperature of the body may be maintained. Whenever, therefore, muscular exertion is severe, or when the individual is exposed to cold and has to produce large amounts of heat, then more energy must be forthcoming, and hence tissue waste is enormously increased. Whereas, if complete rest is maintained, and the animal is kept surrounded by air at a temperature approaching that of the body, the waste of tissue-substance is reduced to a minimum. From this it will be apparent that no conclusions of value with regard to the possible duration of life in the fasting state can be drawn from the records of those exposed to cold and hardships after shipwreck. It will be at once apparent that the amount of energy employed in maintaining the temperature of the body must be very much greater in warm-blooded than in cold-blooded animals. Indeed, in the latter class, where the temperature is at most only a few degrees above that of the surrounding atmosphere, waste of tissue for the production of heat is practically in abeyance. The same may also be said of hibernating animals, which may be regarded during their winter sleep as cold-blooded. For this reason, and because during certain periods their movements are by no means active, cold-blooded animals can endure very prolonged periods of inanition.

When we come to consider the physiology of fasting more closely, we find that the amount of waste of the various tissues of the body is by no means equal. The following figures, indicating the percentage loss of various tissues in an animal dying of starvation, are taken from Voit's article in Hermann's *Handbuch der Physiologie*:

Fatty tissue lost	97 per cent.
Muscle	31 "
Blood	27 "
Brain and spinal cord	8 "
Heart	8 "

We thus see that the more essential tissues feed upon the less essential, and that the fats of the body are the great source of nourishment during inanition. As long as a fair amount of fat remains in the body, the muscle can undergo its chemical changes, disintegrating and yielding energy, but always again undergoing a process of reconstruction. Whenever the fat is used up we find that a

rapid disintegration of muscle-substance without reconstruction occurs, and death rapidly ensues. The onset of this condition is indicated by a rise in the excretion of nitrogen in the Urine (q.v.).

In regard to the symptoms observed during starvation little need be said, since in most cases they are due rather to the conditions which have led to or which accompany the fast. The sensation of hunger is a prominent symptom during the earlier days, but appears to diminish. Emaciation is, of course, invariable—the skin feeling harsh and dry from the loss of subcutaneous fat. The temperature falls below the normal, and lassitude and finally torpor supervenes before death, which appears to occur simply from asthenia. See *A Study of Prolonged Fasting*, by Francis Gano Benedict (Washington, D.C., published by the Carnegie Institution of Washington, 1915).

Fast and Loose, the name of a cheating game, also called *Pricking at the Belt*, which appears to have been much practised by the Gypsies in the time of Shakespeare. The following is Brand's description: 'A leathern belt is made up into a number of intricate folds, and placed edgewise upon a table. One of the folds is made to resemble the middle of a girdle, so that whoever shall thrust a skewer into it would think he held it fast to the table; whereas, when he has so done, the person with whom he plays may take hold of both ends, and draw it away.' The game is still practised at fairs, races, and similar meetings under the name of *Prick the Garter*; the original name, in the phrase 'to play fast and loose,' has gone into the language to designate the conduct of those whose easy ethics do not forbid them to say one thing and do another. See Book XIII. chap. xxix. of Reginald Scot, *The Discoverie of Witchcraft* (1584).

Fasten's E'en. See SHROVETIDE.

Fasti (Lat. *Dies fasti*), those days among the ancient Romans on which it was lawful to transact legal or public business, in opposition to *nefasti*, on which it was not permitted. But the sacred books, in which the lawful days of the year were marked, were themselves denominated *fasti*, and the term was employed, in an extended sense, to signify various kinds of registers, especially the *Fasti Sacri* or *Kalendares*, and the *Fasti Annales* or *Historici*.

The *Fasti Kalendares* or calendars of the year were kept exclusively by the priests for about four centuries and a half after the building of the city. The appearance of the new moon was proclaimed by a pontifex, who at the same time announced to the people the time which would intervene between the Kalends and the Nones. On the Nones the country-people assembled for the purpose of learning from the Rex Sacrorum the various festivals of the month, and the days on which they would fall. In the same way those who intended to go to law learned on what days it would be right (*fas*) to do so. The mystery with which this lore was surrounded, for purposes of power and profit, by the favoured class was dispelled by Cn. Flavius, the scribe of App. Claudius Cæcus, who surreptitiously copied from the pontifical book the requisite information, and published it to the people in the forum. Consequently time-tables (*fasti*) became common, very much resembling modern almanacs. They contained the days and months of the year, the Nones, Ides, lawful and unlawful days, &c., astronomical observations on the rising and setting of the fixed stars, the commencement of the seasons, brief notices concerning the introduction and signification of certain rites, the dedication of temples, the dates of victories, disasters, and the like. In later times the exploits and honours of the imperial family were duly entered in the calendar. The celebrated *Fasti* of Ovid is a sort of poetical year-

book or companion to the almanac, as arranged by Julius Caesar, who remodelled the Roman year.

Several very curious specimens of *fasti* on stone and marble have been discovered, of which the most remarkable are the *Kalendarium Maffeanum* (so called from its first possessor), upon almost all the days of the year; the *Kalendarium Prænestinum* of Verrius Flaccus, discovered in 1770 at Præneste, containing the months January to April and December; the *Kalendarium Vaticanum* (March, April, August), *Venusinum* (May, June), *Esquilinum* (May and June), and *Farnesianum* (February and March). These are printed in vol. i. of Mommsen's *Corpus Inscriptionum Latinarum* (Berlin, 1863), in which the Roman calendar for almost the complete year is elucidated.

The *Fasti Annales* or *Historici* were chronicles containing the names of the consuls and other magistrates of the year, and an enumeration of the most remarkable events in the history of Rome, noted down opposite the days on which they occurred. From its application to these chronicles the word *fasti* came to be used by the poets as synonymous with historical records. Of these, fragments have come down to us, of which the most important are the so-called *Fasti Capitolini*, discovered in the neighbourhood of the ancient forum in the 16th and 19th centuries. See CALENDAR; also Boor, *Die Fasti Censorii* (1873), and Wehrmann, *Die Fasti Prætorii* (1875).

Fastnet Lighthouse, on a rock 4 miles SW. of Cape Clear, with a revolving light 158 feet above high-water. The present tower was built 1899-1904.

Fastolf, SIR JOHN, was born about 1378 at Caistor, near Yarmouth, and 'exercised,' says Caxton, 'the wars in the royaume of France and other countries for forty years enduring.' He distinguished himself at Agincourt (1415), and still more in the 'Battle of the Herrings' (1429), so called because, while conveying supplies to the English besiegers of Orleans, he formed a sort of *laager* of herring-barrels, and with his archers beat off a whole French army. Later in the same year he was less successful against Joan of Arc, and at Patay, according to Monstrelet, whom Shakespeare follows, displayed such cowardice that the Duke of Bedford stripped him of his Garter. This, however, is very questionable; he rather seems to have retained all his honours till in 1440 he came home to Norfolk, and in 1441 he was granted a pension of £20 'for notable and praiseworthy service and good counsel.' His Norfolk life is mirrored faithfully in the *Paston Letters*, where we see him adding to his broad possessions, heaping up riches, building a huge new castle at Caistor—a hard old man, yet not without love of learning and the church, who died 5th November 1459. Anything less like Shakespeare's 'Sir John Falstaff' can hardly be imagined. See Gairdner's *Paston Letters* and Duthie's *Fastolf* (1907).

Fat. See FATS, OBESITY, ADIPOSE TISSUE, OILS.

Fata Morgana, the Italian name for a striking kind of mirage observed in the Strait of Messina. A spectator on the shore sees images of men, houses, ships, &c., sometimes in the water, sometimes in the air, the same object having frequently two images, one inverted. It is so named because supposed to be caused by the fairy (*fata*) Morgana of Arthurian romance. See MIRAGE.

Fate, the Fates, Fatalism, express a conception which has more or less prevailed in all religions. The words are derived from the Latin *Fatum*, which has primarily a passive signification denoting something uttered—a decree or ordinance. The Greeks expressed the same thought by *Eimarmenē*. *Moirā*, again, was the active personification

of the idea—the goddess Fate or Destiny. It constituted in the Greek mythology something like an ultimate monotheistic element—the vague Unity binding together and dominating over the crowd of Olympian deities. With Homer, who in every instance save one speaks of Fate (Moirai) in the singular, Fate was not a deity, but a mere personification, the destinies of men being made by him to depend upon the will of the gods; whilst, according to the later Greeks and the Romans, the gods themselves were subject to the control of the *Moirai* or *Parcae*. Hesiod, however, who is almost contemporary with Homer, speaks of three Fates, whom he calls daughters of Night—Clotho, the spinner of the thread of life; Lachesis, who determines the lot of life; and Atropos, the inevitable. They were usually represented as young women of serious aspect; Clotho with a spindle, Lachesis pointing with a staff to the horoscope of man on a globe, and Atropos with a pair of scales, or sun-dial, or an instrument to cut the thread of life. In the oldest representations of them, however, they appear as matrons, with staffs or sceptres. They had places consecrated to them throughout all Greece, at Corinth, Sparta, Thebes, Olympia, and elsewhere.

With the course of Greek thought the conception of Fate became more spiritualised. In Æschylus it is an inexorable Destiny; in Sophocles and Plato it is more of a free and ordering Will. In the later forms of Greco-Roman speculation, again, it undergoes various modifications. With the Epicureans it seems identical with Chance (*Tuchē*); with the Stoics it is the very opposite of this. In the one case the Absolute is a mere blind fatality; in the other case it is an imminent necessity of reason, governing with iron sway the apparently accidental phenomena of life.

In the two great religions of modern times, Christianity and Mohammedanism, the same conception is found in various forms. In the latter the Highest seems to be conceived as inexorable law, swallowing up every lower law of activity; yet the abject self-subjection to fate generally understood to be implied in the Moslem *Kismet* is by no means inculcated in the Koran (see MOHAMMED). In Christianity and the modern speculation which it has coloured it shows itself less broadly in the well-known doctrines of Predestination and of philosophical Necessity. In the Predestination theory of Augustine, Calvin, and many others, the old fatalistic doctrine is repudiated; the recognition of a free determining element in the divine Will separates their idea of it altogether from that of a mere blind Destiny; but the influence of the mode of thought out of which the old idea sprung appears in the manner in which the divine decrees are sometimes spoken of as inexorably overbearing human freedom. In the doctrine of philosophical necessity promulgated by Leibniz and Edwards, and in a somewhat different form by modern scientific modes of thought, the same idea emerges as inevitable sequence—of an invariable connection linking together all phenomena, material and mental. An immutable law is declared to pervade and harmonise all existence. This is a much higher conception, but is obviously not wholly unrelated to the old pagan doctrine of Fate. See PREDESTINATION, WILL.

Fatehganj ('Victory Market'), the name of two villages and battlefields in Bareilly district, in the United Provinces. (1) EAST FATEHGANJ, 23 miles SE. of Bareilly, was founded by the Nawáb of Oudh to commemorate the British victory over the Rohillas (1774), which gave him possession of a large part of Rohilkhand. (2) WEST FATEHGANJ, about 35 miles NW. of the former, was the scene of another victory over the Rohillas in 1794. There

is a monument over the grave of the Company's troops, and a carved and minareted tomb holds the remains of two Rohilla chieftains.

Fatehgarh, the cantonment and administrative headquarters of Farukhabad district, lies 3 miles E. of the native city of Farukhabad, with which it forms a joint municipality. Government has here an important gun-carriage factory; and there are flourishing settlements of native Christians, established by the American Presbyterian Mission, which was formed in 1838. A British military station since 1802, the place was attacked by Holkar in 1804, and is infamous in the annals of the mutiny of 1857, in the course of which upwards of 200 Europeans—men, women, and children—mostly fugitives brought back after escaping down the Ganges, were sabred or shot, either here or at Cawnpore. Pop., with Farukhabad, 60,000.

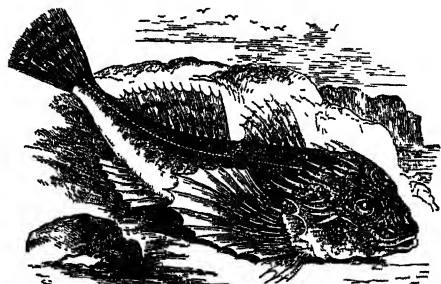

Fatehpur, (1) capital of a district in the United Provinces, on the East Indian Railway, 70 miles NW. of Allahabad. It contains two interesting mosques, and has a trade in ludes, soap, and grain. Pop. 17,000. The district of Fatehpur lies wholly within the Doab (q.v.), and occupies its entire breadth from Jumna to Ganges. Area, 1642 sq. m., more than half of which is highly cultivated; pop. (1911) 676,939, nearly nine-tenths Hindus. (2) A fortified town of Rajputana, 145 miles NW. of Jaipur; pop. 17,300.

Fatehpur Sikri, a former capital of the Mogul empire, was founded by Akbar in 1570, but soon after abandoned for Agra, 23 miles to the east. The remains of the magnificent architectural works with which he and his son enriched it are enclosed by a high stone wall, about 5 miles in circuit, and include several palaces, a noble mosque, and numerous other splendid ruins. Within the bounds of Akbar's wall are the modern town and the village of Sikri, with insignificant manufactures of carpets and millstones. Pop. 6000.

Fathen. See CHENOPODIUM, ORACHE.

Father. See PARENT AND CHILD, FAMILY, INFANT.

Father-lasher, a name applied to two Bull-heads (*Cottus scorpius* and *bubalis*) which occur commonly on British coasts. They have a wide European and American distribution, and belong to the Gurnard (q.v.) family (Cottidae), in the spiny-rayed (Acanthopteri) order of bony fishes. They are both somewhat forbidding little fishes, four or five inches in length, with dark, quaintly mottled skins, and with spines on the head. The head and pectoral fins are large in proportion to the body. The male builds a nest and guards the young. In Scotland the second species is sometimes called the Lucky Proach, while the first species is also known as the Sea Scorpion. Both forms, but

Father-lasher (*Cottus bubalis*).

especially the first, are often left on the shore or among the rocks by the retiring tide.

Fathers of the Church (*Patres Ecclesiastici*), a term which, strictly used, denotes only certain early writers of unimpeachable orthodoxy and eminent sanctity, who have been accepted by the church as duly qualified exponents of her doctrines. The title of 'father' was given in early times to all bishops, confessors, and heads of monasteries (see ABBOT); but the expression 'fathers of the church' has become restricted to this more definite sense, while those writers whose heterodoxy is manifest are called simply *Scriptores Ecclesiastici* ('Church-writers'). The title of 'fathers,' however, is often bestowed on some, such as Origen and Tertullian, the errors in whose writings are overlooked for the sake of the value of their orthodox contents. Historians are generally agreed in excluding from the patristic period the Apostolic Fathers (q.v.), and in dating its commencement from the 2d century; but there is no unanimity regarding the time at which it may be said to have closed. In the Greek Church the period is often brought down to the Council of Florence (1441). Roman Catholic writers include within its limits all writers who were witnesses to the Catholic doctrine of the church during the first twelve centuries of the Christian era, or even down to the Council of Trent; moreover, in 1871-78 Saints Alfonso de Liguori and Francis de Sales, the former of whom died so late as 1787, were raised to the dignity of *Doctores Ecclesiae*. But there appears no good reason why Anselm and Bernard and those that immediately follow them should be removed from the list of the schoolmen, and the patristic period may conveniently be taken to have closed for the Eastern Church with John of Damascus (756), and for the Western with Gregory the Great (604). Even Roman Catholic theologians acknowledge the higher value and importance of the fathers of the first six centuries. Arranged in the order of their deaths, chief among the ante-Nicene fathers are Justin Martyr, Irenæus, Clement of Alexandria, Tertullian, Origen, Cyprian, and Gregory Thaumaturgus; while the post-Nicene fathers include Eusebius of Cæsarea, Hilary of Poitiers, Athanasius, Basil, Cyril of Jerusalem, Gregory Nazianzen, Gregory of Nyssa, Ambrose, Epiphanius, Chrysostom, Jerome, Augustine, Cyril of Alexandria, Leo the Great, Gregory the Great, and John of Damascus. For all these, see separate articles, as well as for many of the other early writers whom the Latin Church includes in the list. In both divisions of the church four authors are recognised as fathers *per eminentiam*: in the East, Athanasius, Basil, Chrysostom, Gregory Nazianzen; in the West, Ambrose, Jerome, Augustine, Gregory. The study of the life and writings of the fathers is sometimes regarded as constituting a distinct discipline, known as patristics or patrology; but this practically constitutes a study of the church's history during the first six centuries. See CHURCH HISTORY. With respect to the authority of the fathers, the Roman Catholic position is that the teaching of individual fathers is to be accepted or rejected on its merits, and their evidence as witnesses to the tradition of the church, either singly or when several concur, is to receive so much credence as may appear due after the quality and circumstances of the testimony have been considered; but their morally unanimous consent is held to carry decisive authority in matters of faith. Protestant writers, on the other hand, while acknowledging the merits of the patristic writings, and recognising in many important points a *consensus patrum*, dwell upon the admitted fallibility of the authors, and insist upon the sufficiency of Holy Scripture, as containing 'all things necessary to salvation.' See EXEGESIS; also INFALLIBILITY.

Editions of individual fathers are noted under their separate articles. Collective editions are De la Bigne's *Maxima bibliotheca veterum Patrum* (Paris, 1575; improved ed. 27 vols. Leyden, 1677—the Greek writings translated into Latin); Gallandi's *Bibliotheca veterum Patrum* (14 vols. Venice, 1765-81); and Migne's exhaustive *Patrologia cursus completus* (387 vols. Paris, 1844-66). This last is continued in Horoy's *Medii ævi bibliotheca patristica, sive Patrologia ab anno 1216 usque ad concil. Tridentinum* (1st series, *Doctores eccl. lat.*, Paris, 1879 et seq.). Also the Vienna Academy has been issuing since 1866 a *Corpus scriptorum ecclesiasticorum latinorum*, based on a critical comparison of MSS., to be completed in about 100 volumes. English translations are numerous. Clark's *Ante-Nicene Library* (Edin. 1864-71) is complete in 24 vols., and the *Library of the Fathers* (Lond. 1833-85), edited by Pusey, Keble, Newman, and others, extends to 48 vols. There is a *Select Library of the Nicene and post-Nicene Fathers* (New York), edited by Dr Schaaf; and there is a series of *Fathers for English Readers* (S.P.C.K., 11 vols. 1878-84). See Farrar's *Lives of the Fathers* (1889), Bright's *Age of the Fathers* (1903), Swete's *Patristic Study* (1904), and Labriolle's *Littérature Latine Chrétienne* (1922).

Fathom, a measure of six feet, principally used in reference to marine soundings, and in mines. Originally a fathom (O.E. *fæðm*) was taken as the width to which the two outstretched arms extended.

Fatimides, or FATIMITES, an Arab dynasty, descended from Ali and Fatima, daughter of Mohammed, ruled over Egypt and North Africa (969-1171), and later over Syria and Palestine. In religion the Fatimides were Shiites of the Ismailian sect. The Fatimide khalif Hakem was the founder of the Druses (q.v.). Compare also KHALIF, EGYPT, ISMAILIS.

Fats are natural oils which occur in plants and animals. They are all *esters* of the triatomic alcohol glycerol, $C_3H_5(OH)_3$, formed by the replacement of the hydrogen of the hydroxyls by the radicles of the fatty acids.

The most abundant fatty acids of the body are—

Saturated	Palmitic Acid	$C_{15}H_{31}COOH$
	Stearic Acid	$C_{17}H_{33}COOH$
Unsaturated	Oleic Acid	$C_{17}H_{33}COOH$

The unsaturated acids are more readily oxidised than the saturated.

The fats of these acids are—

Palmitin	$C_{15}H_{31}O_6$
Stearin	$C_{17}H_{33}O_6$
Olein	$C_{17}H_{33}O_6$

In addition to these, small quantities of the neutral fats of butyric, caproic, caprylic, capric, and myristic acids occur in milk and butter. They are oily bodies; some solid, others fluid, at the ordinary temperature. They are insoluble in water, soluble in hot alcohol, in ether, chloroform, &c. Under the action of caustic alkalies or superheated steam they are decomposed into their fatty acid and glycerin. The fat of different animals differs in its characters according to the relative proportion of these various fats which it contains. Thus, the fat of the dog, which contains a large proportion of olein, melts at a comparatively low temperature, while the fat of the sheep, on the other hand, which is particularly rich in stearin, has a much higher melting-point.

Whatever be the nature of the fat, it occurs in the animal body inside the living units or cells in the form of small globules. Fats appear to be an almost invariable constituent of all living protoplasm; but in certain tissues they accumulate in very large amounts. This is especially the case in the cells of loose fibrous tissue, where the deposition of fat is frequently so great as to form regular

masses or lobules. Under the skin, in the abdomen, in the orbits, round the heart, and in various other places these masses are well marked.

The quantity of fat in the human body varies considerably at different periods of life. In the earlier stages of fetal existence we find scarcely any fat; in new-born children there is usually a considerable quantity of this substance deposited under the skin, and the organism continues rich in fat till the age of puberty, when a marked diminution of the substance occurs. It again increases about middle life, and then occasionally occurs in great excess; for example, three or four inches of fat are not unfrequently found under the skin of the abdomen in corpulent persons.

It has now been clearly shown that an animal takes up and stores in its body any fat which may be administered in the food, and that it may thus for the time being have the chemical nature of its fat materially altered. After a time, however, the living protoplasm of the body seems to be able to convert the foreign fat so stored into the proper fat of the animal.

That carbohydrates—such as sugar and starch—are also sources of fat is a matter of popular belief. Various researches have clearly demonstrated that this belief is correct. By feeding young growing pigs on a diet of known composition, and afterwards killing them and analysing their bodies, it was shown that the fat found was in such amounts that it could have been derived only from the carbohydrates of the food.

The physiological value of the fats is due partly to their physical and partly to their chemical characters. The uses of the fat deposited beneath the skin are, first, to protect the body from external shocks by a uniform diffusion of pressure through the whole adipose tissue; and, secondly, to keep up the heat of the body, by materially checking, through its very slight conducting power, the loss of free heat by radiation. This use of the fat is most clearly seen in some of the lower animals (the seal, whale, &c.), which are exposed to very low temperatures.

The chief chemical use of fat is as a store of potential energy for the body (see FASTING). On account of the large amount of carbon and the small amount of oxygen contained in the molecule, it is peculiarly valuable in this respect. Measuring the potential energy, as is usually done in calories, 1 gramme of fat yields 9.3 calories, while in the body 1 gramme of protein and 1 gramme of carbohydrate each yield 4.1 calories. See also OILS, OBESITY, ADIPOSE TISSUE.

Fatty Acids. See OILS.

Fatuity. See IDIOCY, INSANITY.

Faucher, LÉON, a French publicist and statesman, was born at Limoges, 8th September 1803. He studied at first philology and archaeology, but about the period of the July revolution (1830) betook himself to journalism and political economy. From 1830 to 1842 he was successively editor of the *Temps*, the *Constitutionnel*, and the *Courrier Français*. In 1843 he began to write for the *Revue des Deux Mondes* a series of articles on the industrial condition of England, collected in two volumes in 1845 under the title of *Études sur l'Angleterre*. After the revolution of 1848 he sat in the Constituent and Legislative Assemblies for the department of Maine. When Louis Napoleon was chosen president, Faucher became first minister of Public Works, and subsequently minister of the Interior; but, when the president proposed to appeal to universal suffrage, Faucher gave in his resignation, and withdrew from political life. He died at Marseilles, 14th December 1854. Several of his

most valuable contributions to politics are printed in *Economistes et Publicistes Contemporains*, and in the *Bibliothèque des Sciences Morales et Politiques*.

Faucit, HELEN. See MARTIN, LADY.

Fault, or DISLOCATION, a term used in Geology to characterise certain displacements common among rocks. Rocks have been fractured and displaced, or shifted along the line of breakage. Such faults may occur with or without distortion of the fractured rock-masses. Sometimes the fissure is smooth and close. In other cases the rocks are jumbled and shattered along the line of dislocation, and the fissure (sometimes several yards in width) is often filled with a breccia of blocks and debris forming what is termed *fault-rock*. The opposite walls of a fault are not infrequently smoothed, polished, and marked with rectilinear striae, which are called *Slickensides* (q.v.), and similar markings frequently occur on the faces of the joints that invariably abound in rocks in the neighbourhood of faults. Dislocations are rarely quite vertical, their inclination from the vertical being called their *hade*. The diagram shows one of the simplest kinds of fault. The amount of vertical displacement of the beds is the *amount* of the throw, and is measured by protracting a line across the fault, from the truncated end of some particular bed, *a*, until it is reached by a perpendicular, A.B, dropped from the other end of the selected stratum. All normal faults hade in the direction of downthrow, so that when a miner meets a dislocation, he has only to look at the hade to ascertain at once whether he must seek for

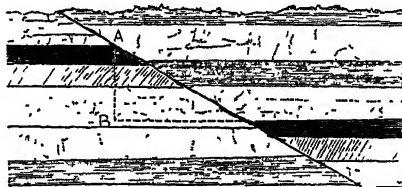

Diagram of Dislocated Strata.

the continuation of the displaced seam at a higher or lower level. Thus, if he happened to work the coal-seam, *a*, shown in the diagram, up to the dislocation at *A*, he would see from the hade of the fault that the missing seam must be sought for at a lower level, and he would describe the fault as a downthrow or downcast; whereas, if he reached the fault from the lower level, he would call it an upthrow or upcast. There is another class of faults in which the hade is not in the direction of downthrow: these are termed *reversed faults*. They rarely occur in strata which are not highly folded and plicated, but in regions where the rocks give every evidence of great lateral crushing and squeezing, as in true mountains of elevation, they are of common occurrence. Remarkable faults of this kind have been discovered in the north-west of Scotland. The inclination from the vertical of some of these faults is very great; in fact some approach horizontality, so that the strata on the high side overlies the rocks on the lower side of the fault. Like successive strata in a conformable series. One set of rocks belonging to a low horizon has been pushed horizontally over the surface of another set pertaining to a higher horizon for distances of 10 and even 20 miles. The amount of vertical displacement produced by normal faults may vary from an inch or two up to many thousand feet. Thus, the great fault between the Highlands and Lowlands of Scotland has a downthrow of not less

than 8000 feet, while the similar dislocation between the Lowlands and Southern Uplands of the same country amounts in places to 15,000 feet.

Fauna, a term employed to designate animals collectively, or those of a particular region, or of a particular geological period. Thus, we speak of the fauna of Great Britain, the recent fauna, the fossil fauna, the fauna of the Eocene period or formation, &c. The term bears the same relation to the animal kingdom that *Flora* does to the vegetable. Its derivation is from the mythological fawns, regarded as the patrons of wild animals. In the fauna of any region are included only those animals which are indigenous to it, and not those which have been introduced.

Fauns. Faunus, grandson of Saturn, was an ancient Italian king, who instructed his subjects in agriculture and the management of flocks, and was afterwards worshipped as the god of fields and of shepherds. The festival of the *Faunalia*, held on the 5th December, referred to the protection he exercised over agriculture and cattle. *Fauna* was his female complement. He was also worshipped as a prophetic divinity. As deity of the woods and of flocks and herds, he corresponds to the Greek Pan, and hence with his name became associated the attributes of the latter. The idea also arose of a plurality of Fauns, like the Greek Satyrs, who were represented with short horns, pointed ears, tails, and goats' feet, and to whom all terrifying sounds and appearances were ascribed. Readers of Hawthorne's *Marble Faun* (or *Transformation*) will remember the artistic use there made of the conception.

Fauntleroy, HENRY, forger, was born in 1785, and at fifteen entered the London banking-house of Marsh, Sibbald & Co. His father had been one of the original founders, and on his death in 1807 the son became a partner, and ere long almost its sole manager. In 1824 it was discovered that the signatures of two trustees for a sum of £1000 had been forged four years before for the purpose of selling the stock, while Fauntleroy had been paying the dividends regularly ever since. Other and much larger transactions of the same nature were discovered, and Fauntleroy was put on trial (30th October) with seven separate indictments against him, the one on which the attorney-general most relied being a forged deed in his sister-in-law's name for a transfer of £5480. A paper in Fauntleroy's handwriting was produced in which he confessed to having forged powers of attorney in order to save the credit of the house. The prisoner was condemned to death. The case excited great interest, and many influential persons exerted themselves to procure a commutation of the penalty, but without success. Fauntleroy was hanged, 30th November 1824, in the presence of a vast multitude of spectators. See Griffith's *Chronicles of Newgate* (1884).

Faure, FRANÇOIS FÉLIX, President of the French Republic, was born in Paris, 30th January 1841, was for a time a tanner in Touraine, but became a wealthy ship-owner in Havre, and an authority on all questions concerning shipping, commerce, and the colonies. During the Franco-German war he commanded a body of volunteers, and gained the ribbon of the Legion of Honour. He entered the Assembly in 1881, served as Colonial and Commercial Minister in the cabinets of Gambetta, Jules Favre, and Tirard, and as minister of marine in that of Dupuy. A moderate republican, he was elected president of the republic on the resignation of Casimir-Périer in 1895. He died 16th February 1899.

Fauré, GABRIEL URBAIN, organist and composer, born 13th May 1845 at Pamiers, Ariège, was organist in various Paris churches, and director of the Conservatoire. He died 4th November 1924.

Fauriel, CLAUDE CHARLES (1772-1844), was born at St Étienne, served in the army and was secretary to Fouché, but soon devoted himself entirely to letters. He put in circulation, says Renan, a greater number of ideas than any contemporary writer. After the July revolution he became a professor in the Paris Faculté des Lettres, and was elected to the Academy of Inscriptions in 1836. His earliest works were translations. In 1836 he published his chief work, *Histoire de la Gaule Méridionale* (4 vols.); the year after, an edition of the Provençal rhymed chronicle on the crusade against the Albigenses. A very important essay was *Sur l'Origine de l'Épopée du Moyen Âge* (1833). His *Histoire de la Poésie Provençale* (3 vols. 1846), which claimed for the Provençals the greater portion of the romances of chivalry, and his *Dante et les Origines de la Littérature Italienne* (1854) are based on his lectures. See Sainte-Beuve's *Portraits Contemporains*.

Faust, DR, a famous dealer in the black art, whose legendary story, a product of the Reformation period, has filled a great place in literature. The historical person who bore the name of Faust lived in the first half of the 16th century, and can be traced in the testimonies of contemporaries from 1507 down to about 1540. He was born at Knittlingen in Württemberg, or, according to others, at Roda, near Weimar. His parents were poor, but the bequest of a rich uncle enabled him to study medicine and magic at Cracow. From a letter of the Abbot Trithemius of Spanheim, written August 20, 1507, we find an account of him first at Gelnhausen the year before, then at Wurtzburg, next at Kreuznach, under the name of Georgius Sabellicus *Faustus junior*. He is described as a vagabond, boastful and pretentious, giving himself out as skilled in necromancy, astrology, magic, chiromancy, agromancy, pyromancy, and hydromancy, able to restore by his own genius the works of Aristotle and Plato if they were lost, and reproduce as often as required all the miracles of Christ. At Kreuznach he was employed to teach by Franz von Sickingen, but was soon obliged to flee for his abominable debaucheries. In 1509 one Johann Faust was pursuing his studies at Heidelberg, where he took the degree of bachelor of theology, and may be the same as the vagabond scholar whom Trithemius denounced. Mutianus Rufus, in a letter to Henri Urbain in 1513, speaks with contempt of one Georgius Faustus at Erfurt, whose follies—as those of a stranger—are of no consequence. Here he seems to have made long and frequent sojourns, if the chronicle first published by Mutschmann may be accepted as contemporary evidence; and, moreover, the main elements in his story appear to be already formed. In 1516 we find him at Maulbronn, next in 1525 (traditionally) at Leipzig; in 1528, as Dr George Faust of Heidelberg, he was expelled from Ingolstadt. The physician Philip Begardi, in his *Index Sanitatis* (1539), speaks of him as having been for some years known as a rogue and a vagabond who gave himself out as *philosophus philosophorum*, and was highly renowned among his dupes for his great skill, not alone in medicine, but also in chiromancy, necromancy, physiognomy, crystallogancy, and the like other arts. Begardi had not himself seen him, but had many accounts of him. A somewhat ambiguous sentence at the end of the passage about Faust has been interpreted as conveying the fact that he was just dead, and certainly after 1539 we have no positive proofs of his existence, while we

know that he was dead by 1544. The Protestant theologian Johann Gast, in the second volume of his *Convivialium Sermonum Liber* (1544), speaks of having supped with Faust at Basel, where he was attended by a dog and a horse that were evidently demons, and further describes his deplorable end, how the devil strangled him, and how his dead body lay constantly on its face on the bier, although as often as five times turned upwards.

Conrad Gesner of Zurich, in a letter written in 1561, mentions him as a wandering scholar of marvellous powers, long since dead. Next Manlius, a pupil of Melanchthon, tells us in his *Locorum Communium Collectanea* (1562) that his master knew Faust, who was a native of Kundling in his own country, and described him as 'turpissima bestia, et cloaca multorum diabolorum.' He described further how he had studied magic at Cracow, worked many vain wonders throughout Germany, and was at last carried off by the devil some years before. Joannes Wierus, a pupil of Cornelius Agrippa, in his *De Præstigiis Daemonum* (1583), speaks of Faust as having been born at Kundling and educated at Cracow, and as having travelled over all Germany, and been imprisoned for his misdeeds in a town in Holland. He tells two stories of him which harmonise with the tradition. According to Widman, Luther in his conversations spoke freely of Faust and his familiar in illustration of the craft and wickedness of the devil, and of the necessity of avoiding all perilous dealings with him. Faust he condemned as the typical infidel and impious man, as well as the mere profligate and the vagabond. Here we see the beginnings of the religious colour which was later to become one of the main characteristics of the story. Count Froben Christoph von Zimmern in his *Chronik* twice alludes to Faust, confirming the account that he died in an inn during the night at the hands of his familiar when his hour had come. One of the last notices of Faust before the publication of the *Volksbuch*, which was to fix the form of the legend for all time, is that of Augustin Lercheimer of Steinfeld, a Protestant theologian, and, like Manlius, a pupil of Melanchthon. In his *Christliche Bedenken und Erinnerung von Zauberei* (1585) we find frequent notices of Faust, and in the minuteness of his details we see the legend full-grown. Again, in two among the seventeen tracts composing the *Theatrum de Veneficis* (1586) there is distinct mention of Faust. Martin Delrio, in his *Disquisitionum magicarum Libri sex* (1624), and Philip Camerarius, in his *Operæ Horarum Subcisi-vorum* (1658), testify further to his story.

The first literary version of the Faust story was the *Volksbuch*, published by Johann Spies at Frankfurt in 1587, under the title *Historia von Dr Johann Fausten, dem Weitbeschreiten Zauberer und Schwartzkünstler, &c.*, of which but five copies are in existence—one in the British Museum. At the close of the dedication Spies explains that he has printed the book for a warning to all Christians, and tells how he had received his version of the legend from a friend at Spire, evidently a Protestant theologian from the Scripture texts with which it is scattered. The 'preface to the Christian reader' is an admirable sermon upon the damnable consequences of magic and commerce with the devil. The book is divided into sixty-eight chapters, unequally arranged in three parts and a conclusion. The first part recounts, in seventeen chapters, the birth of Faust at Roda near Weimar, his early studies and bold speculations, his meeting with the devil in a wood near Wittenberg, and his three several disputations in his own dwelling with the fiend, who gives his name as Mephistophiles, when the compact is concluded by which Faust signs away

his soul in blood drawn from a vein in his left hand, in return for the services of Mephistophiles for twenty-four years. The fiend now supplies him with the means wherewith Faust and his *famulus* Wagner are able to live in the greatest luxury. Ere long Faust wishes to marry, but is not allowed, as marriage is an institution of God, and therefore hateful to the devil. Then follow the answers of Mephistophiles to Faust's questions about hell and its ten governments, the form and figure of the fallen angels, the power of the devil, the division of hell called Gehenna, its creation, and the tortures peculiar to it.

The second part contains fifteen chapters relating to the rest of Faust's questions about astronomy and astrology, the causes of winter and summer, the creation of the firmament; after which follow the false answers of the fiend about the creation of the world and the birth of man, and the account of Faust's earliest adventures, including a visit to hell and an account of its hierarchy, a journey to the stars, riding upon Mephistophiles in the form of a horse with the wings of a diomedary, and next to many distant countries and famous cities, as Paris, Naples, Venice, and Rome. Here he torments and bewilders the pope with his strange enchantments, remaining three days invisible in the papal palace, seeing in the pope and his attendants countless sins like his own—shamelessness, audacity, pride, presumption, gluttony, drunkenness, luxury, adultery, and impieties of all kinds. At Constantinople he lives royally in the sultan's palace in the form of Mohammed, returning to Wittenberg after a year and a half's absence.

The third part, in twenty-eight chapters, narrates the conclusion of Faust's adventures, and especially the mighty deeds done by his necromancy at the courts of divers potentates. At Innsbruck he calls up the shades of Alexander the Great and his wife for the delectation of the Emperor Charles V., and afterwards plays many tricks upon his knights—planting a stag's horns on the head of one, devouring a peasant's load of hay together with the horse and wagon, and producing fresh apples and grapes in January; and at carnival time he revels with a company of students, drawing forth wine from a table, and raising Helen of Troy from the shades to gratify their eyes with the sight of her beauty. The story tells further of his debaucheries, and of the seven diabolical succubæ whom he made his concubines; and lastly of his liaison in the last year of his term with the famous Helen of Troy, who bore him a son whom he named Faustus junior. As the end approached he was filled with profound melancholy, seeing hell yawning before his eyes and its unutterable torments, from which there was for him no possible escape, while the wicked spirit now began to torment him with cruelly ironical raillery. On the night on which his twenty-four years expired he was in company with a group of students in a tavern of the village of Rimlich, near Wittenberg, and to them he made a long address expressing his deep penitence, after which he remained alone in his chamber. At midnight a fearful storm arose; horrible hisses as of a thousand serpents were heard, and for a little the agonising cries of Faust with a hollow and suffocated sound; but soon all was still. In the morning the floor of the room was found stained with blood, his brains were spattered upon the walls, and his body was found outside, lying near a dunghill, the head and every member hanging half torn off. Helen and her child had disappeared, and the *famulus* Wagner succeeded as heir to his master's property. The history ends with an edifying conclusion.

This *Volksbuch*, which we have seen is not a product of the imagination, at once became popu-

lar, as many as four impressions being printed before the close of the following year. A second and corrected edition was published by Spies himself in 1588. In the same year a Low German rendering was published, and a close though somewhat shortened English translation before 1589, the earliest copies not being dated. See the reprint in W. J. Thoms's *Early English Prose Romances* (new ed. 1906). Danish, Dutch, Flemish, and French versions were also made—the last not till 1598. A Berlin edition of 1590 added six new chapters, of which one relates to the Leipzig tradition of Faust's adventures in Auerbach's cellar. A version of the book in rhyme, executed by Tübingen students, appeared there in 1588 (printed in vol. xi. of Scheible's *Kloster*, 1849). At Hamburg in 1599 was issued the second form of the popular book, the enlarged version of Widman (printed in vol. ii. of Scheible's *Kloster*, 1846). Many additional stories and details are here inserted, and each chapter concludes with an edifying discourse, called a *reminder* (*Erinnerung*), which reveals a violently Protestant bias, extorting everywhere a moral against Rome. A later version of Widman is that by the Nuremberg physician, Johann Nicol. Pfitzer (1674; new ed. by A. v. Keller, Stuttgart, 1880), which is chiefly interesting as containing the prototype of Goethe's *Gretchen* in the citizen's daughter whom Faust wishes to marry, which the devil will not permit him to do. Yet another version was issued at Frankfurt about the beginning of the 18th century, by 'One with Christian Intentions,' in an abridged and modernised form, which was the basis of many widely diffused chapbook impressions (see 'Des Christlich Meynenden Geschichte Faust's,' in vol. ii. of Scheible's *Kloster*, from an edition dated 1728). The life of Christopher Wagner (Scheible's *Kloster*, vol. iii. 1846) was issued in 1593, and originated in the same year an imitation, rather than a translation, in English. It closely follows the form of Faust; Wagner is attended by an ape-shaped attendant devil named Auerban, has similar adventures to his master's, and in the end shares the same fate.

Independent poetic versions of the Faust story also began early to appear. Of these, the earliest, and still the greatest but one, was Marlowe's *Tragic History of the life and death of Doctor Faustus*. English itinerant players traversed Germany in the beginning of the 17th century, and may have carried with them Marlowe's magnificent tragedy, but the popularity of the theme was so great that it may well have inspired the native imagination also, and given rise to the numberless marionettes in which the story was continuously represented down to the present century. These were seldom printed, and usually largely extemporised, keeping at the same time more or less closely to the theme. See the excellent Ulm piece and others in vol. v. of Scheible's *Kloster* (1847); also the marionette versions edited by W. Hamm (1850; Eng. trans. by T. C. H. Hedderwick, 1887), O. Schade (1856), K. Engel (1874), Bielschowsky (1882), Kralik and Winter (1885), and Mentzel (1900).

Lessing had projected two versions of the story, one close to the original legend, the other with the supernatural element eliminated; but of these only some fine fragments now exist. Klinger worked the subject into a romance, *Fausts Leben, Thaten, und Höllefahrt* (1791; translated into English by George Borrow in 1826); and Klingemann published in 1815 his absurd tragedy, 'the hero of which,' says Carlyle, 'is not the old Faust driven desperate by the uncertainty of human knowledge, but plain John Faust, the printer, driven desperate by an ambitious temper and a total deficiency of cash.' Heine's ballet, *Der Doctor Faust, ein Tanzpoem*, appeared in 1851, and N. Lenau's really poetical

epico-dramatic *Faust* in 1836. The *Faust* made known to the English public by Henry Irving was a free adaptation of Goethe's Part I. by W. G. Wills (1885). Librettos were written by Bernard for Spohr (1814), Gandonnière for Berlioz (1846), and by Barbier and Carré for Gounod (1859).

Of artistic representations of Faust all the world knows the fine engraving by Rembrandt finished by Van Vliet (1630). Next came those by Christoph von Schem (1677). The most famous illustrations to Goethe's *Faust* have been those of Cornelius, Retzsch, Seibitz, Kaulbach, and Kreling. The first of the two ancient mural paintings in Auerbach's cellar at Leipzig represents Faust sitting at the head of the table under a revel; the second, as being by magical art carried out into the street sitting astride a wine-cask. Since Goethe's time many fresh paintings have been added to the two venerable studies.

But it is time to come to the greatest genius who has ever experienced the spell of this ancient legend. 'The marionette fable of *Faust*,' Goethe says, 'murmured with many voices in my soul. I too had wandered into every department of knowledge, and had returned early enough satisfied with the vanity of science. And life, too, I had tried under various aspects, and always came back sorrowing and unsatisfied.' Goethe had thought out his *Faust* as early as 1774, but did not publish the first part of his greatest work till 1808, the second till 1831. In his hands it has become a splendid masterpiece, the most really original, moreover, of all his works, although, indeed, in the details of the plot he has invented nothing. It will remain a magnificent dramatic realisation of the elemental struggle between the higher and the lower natures in man. Impossible as it is to compare the English with the German *Faust*, it is still true that Marlowe's conception of the character has the stronger grasp of the actual. His Faust is always a man, real and living; Goethe's is often idealised and subtilised to the point of being a shadow, or rather a symbol.

See Sommer, in Part 42 of Ersch u. Grüber's *Encyclopädie* (1845); Duntzer, *Die Sage vom Doctor Faustus* (1846); Ristelhuber, *Faust dans l'Histoire et dans la Légende* (1863), to be read with caution; Dr Ernest Faligan's admirable *Histoire de la Légende de Faust* (1888), with its excellent 'index bibliographique'; Kiese-wetter, *Faust in der Geschichte und Tradition* (1893); and Rudolf Frank, *Wie der Faust Entstand* (1912). A complete bibliography of Faust literature is Karl Engel's *Zusammenstellung der Faustschriften* (1885).

Faust, JOHANN, printer. See FUST.

Faustina, mother and daughter, wives of two of the noblest among the Roman emperors. The elder, Annia Galeria, usually spoken of as *Faustina Senior*, was the wife of Antoninus Pius, and died 141 A.D.; the younger, known as *Faustina Junior*, was married to his successor, Marcus Aurelius Antoninus, and died at a village near Mount Taurus in 175 A.D. Both, unless maligned by partisan historians, were notorious for the profligacy of their lives, yet after their deaths their memories were marked with signal honours by their forgiving husbands. Institutions for the relief of poor girls were founded by both emperors, and were called '*puellae alimentariae Faustinae*.'

Favara, a town of Sicily, 4 miles SE. of Gigeniti, with sulphur-mines and marble-quarries. Pop. 25,000.

Favart, CHARLES SIMON, a French dramatist, was born at Paris, 13th November 1710, and first became known by his *La Chercheuse d'Esprit*, performed in 1741. In 1745 he became director of the *Opéra Comique*, where he and his wife (a singer and actress, who had a share in the composition of several of her husband's plays) made the first

attempt to harmonise the costume of the actors and actresses with their impersonations. This excited the jealousy of the other theatres, and the *Opéra Comique* was closed in the first year of its existence. After spending some time in Flanders, with a troupe of comedians, in the army under Marshal Saxe, Favart returned to Paris and continued to write operas. He died 12th May 1792. His most celebrated pieces are *Le Coq du Village*, *Bastien et Bastienne*, *Ninette à la Cour*, *Les Trois Sultanes*, and *L'Anglais à Bordeaux*. An edition of his works in ten volumes was published at Paris in 1810; *Les Mémoires et la Correspondance de Favart*, giving delightful glimpses of the literary and theatrical world of the 18th century, was published at Paris in 1809 by his grandson.—*Madame Favart* is the subject and the title of a popular comic opera (1878) by Offenbach.

Faversham, an ancient municipal borough and river-port of Kent, 52 miles by rail ESE. of London, and 10 WNW. of Canterbury, chiefly consists of four streets forming an irregular cross. It has a valuable oyster-fishery, and sends much agricultural produce to London. The creek on which it is situated admits vessels of 200 tons. In the vicinity are important powder-mills. Pop. (1851) 4595; (1921) 10,870. Under the name of Favresfield it was a seat of the Saxon kings, where Athelstan in 930 held a Witenagemot. It has scanty remains of a Clugniac abbey founded (1147) by King Stephen, whose tomb is pointed out in the parish church. This is a fine cruciform building, Early English in style, with a spire 148 feet high. Near it is the house of 'Arden of Feversham,' whose murder by his wife in 1551 forms the theme of an anonymous tragedy (1592; edited by A. H. Bullen, 1888; Thorndike, 1910; Farmer, 1911). A grammar-school, founded in 1527, was rebuilt outside the town in 1879. In 1688 James II. was seized at Faversham, attempting to flee to France.

Favre, JULES CLAUDE GABRIEL, a French advocate and statesman, was born at Lyons, 21st March 1809. He studied for the bar at Paris, and took an active part in the July revolution of 1830. As the defender of the *Mutuellistes* at Lyons in 1831, and in 1835 of those who had been impeached in April, he displayed a spirit of the most ardent and uncompromising republicanism; and in the February revolution of 1848 he wrote the notorious circular for which Ledru-Rollin's administration was so severely reproached, investing the commissioners of the republic with dictatorial authority in the provinces. On being elected deputy to the Constituent Assembly for the department of the Loire, Favre became a member of the Committee of Foreign Affairs, and advocated the prosecution of Louis Blanc. After the election of the 10th December he showed himself a persistent antagonist of Louis Napoleon, and after the flight of Ledru-Rollin became the virtual leader of the Mountain. The *coup d'état* closed his political career at this time, and compelled him to return to his profession. In 1858 he defended Orsini, on his trial for a conspiracy to murder; this procured his election as member of the Legislature for Paris, and he became one of the leaders of the republican party against Napoleon III. In September 1870, after the downfall of the empire, he was appointed minister of Foreign Affairs, and carried on negotiations, though fruitlessly, with Bismarck. But in January 1871, when settling the terms of the capitulation of the capital, he committed the very serious blunders of omitting Bourbaki's army from the armistice and allowing the National Guards of Paris, contrary to Bismarck's advice, to retain their arms, thus facilitating the outbreak of the Commune. He resigned office in July 1871, and

resumed practice at the bar. Favre died at Versailles on 20th January 1880. He was greatest in political repartee, and though long accustomed to public stife, his language was noted for its Attic elegance. See Martain, *Jules Favre, Mélanges Politiques* (1882); Reclus, *Jules Favre* (1912).

Favus (Lat., 'a honeycomb'), a disease of the skin, chiefly of the hairy scalp, characterised by yellowish dry incrustations of more or less roundish form, and often cup-shaped, composed of the Sporules and Mycelia (q.v.) of a vegetable growth belonging to the order of Fungi (q.v.), with usually an unpleasant mousy odour. The discs of favus are produced with great rapidity, and spread rapidly, if not attended to at the first, over the whole scalp, destroying the bulbs of the hair, which becomes very short and thin, and then falls out altogether. Favus is a disgusting and unsightly, but hardly a dangerous disorder; it is, beyond doubt, contagious, but only spreads where cleanliness is greatly neglected, and is therefore almost unknown among the better classes. It is far more common among children than among adults, often affecting those in delicate health, and seems to be more frequent in Scotland than in England, and more frequent also on the Continent than in either England or Scotland. It seems to be gradually diminishing in frequency. On the general surface of the body it is easily cured; but on the hairy scalp its eradication is a matter of great difficulty. The treatment consists in careful removal of the crusts and scrupulous cleanliness, pulling out the hairs from affected parts by the roots, or removal of all the hairs by applications of the X-rays. Thereafter an ointment of copper sulphate 10 per cent. in lard, of resorcin, &c., is perseveringly rubbed in daily. Favus, if allowed to run its course unchecked, is almost always followed by permanent baldness of the parts affected; unlike Ringworm (q.v.), which is a minor disease of the same order.

The Favus fungus, *Achorion Schenleinii*, is nearly allied to the fungus which is so destructive to vines, and has by some botanists been placed in the same genus, *Oidium*.

Fawcett, HENRY, was born at Salisbury, 26th August 1833, son of the mayor of the city, a decided Liberal. He went in 1852 to Cambridge, where in 1856 he graduated as seventh wrangler, and was elected to a fellowship at Trinity Hall, and commenced to read for the bar. In September 1858, when they were shooting, shots from his father's gun entered both Fawcett's eyes, totally blinding him. He was a candidate for parliament at Southwark in November 1860, and was defeated at Cambridge in 1863 by the Conservative candidate. His *Manual of Political Economy* (often re-edited) led to his election to the chair of Political Economy at Cambridge in 1863, a post which he held until his death. Other writings are *The Economic Position of the British Labourer and Protection and Free Trade*. In 1864 he stood for Brighton, but was defeated; but in 1865 he was elected, and again in 1868. His independence of party ties was often misconstrued as half-hearted Liberalism. His so-called 'Tea-room' party virtually ensured the passing of Disraeli's Household Suffrage Bill of 1867. He urged forward measures for the abolition of religious tests at the universities, the extension of the Factory Acts to agricultural children, the promotion of compulsory education, the preservation of commons and open spaces, and the better government of India. He strongly opposed in 1873 Gladstone's Irish University Bill; and he introduced a bill for the abolition of tests in Trinity College, Dublin. In 1874 Fawcett lost his seat for Brighton, but was elected for Hackney. He joined cordially with his party in opposing Beaconsfield's policy

on the Eastern question; and continuing his work for India, was popularly known as 'the member for Hindustan.' He opposed legislative restrictions upon the industry of women, and was a warm supporter of their claims to representation. In 1880 Fawcett was again elected for Hackney, and Gladstone made him Postmaster-general. He introduced the parcel post, postal orders, and sixpenny telegrams. He died 6th November 1884. See *Lives* by Sir Leslie Stephen (1885), W. Holt (1915).

His wife, **MILICENT GARRETT**, was born at Aldeburgh, 11th June 1847. After her marriage (1867) she interested herself in the women's suffrage movement and the education of women. She was created G.B.E. in 1925. Her principal works are *Political Economy for Beginners* (1870); *Essays and Lectures* (jointly with her husband, 1872); *Tales in Political Economy* (1875); *Some Eminent Women of our Time* (1889); *Life of Queen Victoria* (1895); *Life of Sir William Molesworth* (1901); *What I Remember* (1924). She wrote on **WOMEN'S RIGHTS** for this work.

Fawkes, GUY, conspirator, was born in York of Protestant parentage in 1570. Becoming a zealous Catholic before he was of age, he served in the Spanish army in the Netherlands from 1593 until 1604, when he crossed to England at Catesby's invitation. For his share in the Gunpowder Plot (q.v.) he was hanged 31st January 1606.

Fáy, ANDRÁS (1786-1864), a Hungarian poet and author, born at Kolony, was educated for the legal profession, but abandoned it for literature, writing fables, plays, romances, and tales. The fables show richness of invention, simplicity of design, and truth of character. Of the novels the most interesting are *The House of the Bellekis* (1832) and *Doctor Fajor* (1855), both humorous. From 1825 to 1840 Fáy was one of the chief leaders of the Liberal opposition. He was the founder of the first savings-bank at Pest, and one of the founders of the Hungarian national theatre.

Fayal, one of the Azores (q.v.). The island (area, 69 sq. m.; pop. 25,000) is fertile, has a mountain 3000 feet in height, and on its south-east coast a bay with good anchorage, on which stands the town of Horta.

Faye, HÉRVÉ AUGUSTE ÉTIENNE (1814-1902), French astronomer, born at Saint-Benoît-du-Sault, became in 1873 professor at the Ecole Polytechnique, and in 1878 director of the Paris Observatory. In 1843 he discovered Faye's comet; and in 1872 propounded the sun-spot theory of the weather, restated in *Tempêtes ou Tornados* (1897).

Fayetteville, capital of Cumberland county, North Carolina, at the head of navigation on the Cape Fear River, 53 miles S. of Raleigh, has cotton-mills, and exports naval stores, &c.; pop. 9000.

Fayûm, a province of Upper Egypt (pop. in 1917, 517,617), consisting in a nearly circular depression or oasis, about 30 miles in diameter, sunk beneath the level of the Libyan desert (and of the sea), about 80 miles by rail SSW. of Cairo and 15 miles west of the Nile, with which it is connected by a narrow, perhaps artificial, pass through the encircling hills, through which flows the ancient canal, now called the Bahr Yûsuf (after its restorer, Saladin), which, in the absence of the springs common to other oases, irrigates the Fayûm and makes it one of the most fertile provinces of Egypt. The construction of the dam at Assuan considerably added to its cultivable area, and three crops can be raised in a year and a half. The Fayûm abounds in fruit, especially figs and grapes; from its rose-gardens is distilled the Egyptian attâr of roses; and its well-irrigated fields produce heavy crops of cereals, rice, cotton,

flax, and hemp. In 1902 discoveries were made of fossil animals, and evidence has been found that the oasis was inhabited by a neolithic race. It has always been renowned for its fertility, and the irrigation in Pharaonic times was regulated by a system of canals, embankments, and sluices connected with a reservoir, Lake Mœris (q.v.). Traces of the ancient irrigation works may still be seen, and the obelisk of Elbgig and the colossi of Amenemhat III. at Biahmu were connected with them; the latter standing on the pier or quay of the port of the ancient capital, Crocodilopolis (see *MEDINET-EL-FAYÛM*). The pyramid of Useresen II. at Illahun, and the brick pyramid of Amenemhat III. at Hawara, probably mark the ends of the channel (Mewi) connecting the reservoir with the Bahr Yûsuf. Both kings belonged to the XIIIth dynasty, or about 2500 B.C., and the famous 'Labyrinth,' or palace of Amenemhat III., which was reckoned as one of the 'wonders of the world,' may still be traced in the vestiges of numerous chambers about Hawara. Large quantities of papyri of the Ptolemaic and Roman periods found here testify to the prosperity of the oasis, and Coptic manuscripts have also been unearthed. See *PAPYRUS*. The modern capital is Medînet-el-Fayûm.

Fazy, JEAN JAMES, Swiss journ list and publicist, was born at Geneva, 12th May 1796. His early life was spent in Paris, where he acted as a political journalist in the ranks of the Liberal opposition. Returning to Geneva in 1833, he founded the *Revue de Genève*, and became the leading spirit in the radical movement which resulted in the new constitution of 1846. From this latter year until 1861 he was the real ruler of Geneva, and it is due to his influence that the city has of late years been enriched with numerous fine public buildings. Fazy died on 5th November 1878. He wrote a *History of Geneva* (2 vols. 1838-40), and a *Treatise on Constitutional Legislation* (1874).

Feal and Divot (words both meaning turf), in the law of Scotland, are usually conjoined with the word *Fuel*, as 'Fuel, Feal and Divot,' to denote the rural servitudes which give right to the proprietor of the dominant tenement to dig and win peat and turf from the servient tenement for fuel, or for building fences, or thatching houses, or similar purposes. They involve also a right of access to the peat-ground, and a right of using the ground to dry the cut turf.

Fear. See **FORCE AND FEAR**.

Fear, CAPE, the most southerly point of North Carolina, forms the southern extremity of Smith's Island, at the mouth of the Cape Fear River. It has a lighthouse, with a light 110 feet above the sea.—Cape Fear River, formed by the Deep and Haw rivers, runs south-east, and enters the Atlantic after a course of 250 miles, more than half of which is navigable for steamboats; it is the largest river whose course is entirely within the state.

Feasts. See **FESTIVALS**.

Feather-grass (*Stipa*), a genus of grasses remarkable for the long awns which give a peculiar and very graceful appearance to the species, mostly natives of warm temperate climates, and including *Esparto* (q.v.). *S. pennata*, *S. capillata*, and *S. elegantissima* are favourite ornaments of gardens. When gathered before the seeds

are ripe, its feathery awns remain attached, so that the tufts retain their beauty throughout winter. The feathery awns not only assist in the diffusion of the seed, which is carried by the wind to great distances, but in a very interesting manner help to fix it in the soil. Being very hygroscopic, the awn lengthens or shortens with each change of moisture, and each lengthening thus tends to push the sharp pointed grain a little into the earth, its return being prevented by barbed hairs. The awns are hence sometimes used to make rough hygrometers.

Feather River, California, a feeder of the Sacramento, rises in two forks in the Sierra Nevada, and has a southerly course of about 250 miles. It is navigable for steamboats to Marysville, and large quantities of gold have been found on its banks.

Feathers, modified outgrowths of integument, characteristic of birds, and belonging to the same series of skin-structures as the scales of reptiles and the hairs of mammals. There are no transitions known between scales, feathers, and hairs, and each has its characteristic mode of development; but it seems probable that a feather corresponds to a pair, at least, of a scale.

Feathers must have been very early acquisitions of birds, since the most ancient form we know of—*Archæopteryx* from Jurassic strata—already possessed them. See **HAIR**, **SCALES**.

Structure.—An ordinary feather exhibits two principal parts—axis and barbs. The axis is divided into a bare, hollow, inferior portion—the quill, and a barb-bearing, solid, upper part—the shaft. At its base the quill is partly imbedded in a small sac of the skin, and shows at the very end a small aperture for the entrance of the nutritive vascular pulp. The barbs or small plates, which together form the vane, are linked together by pointed lateral barbules, which may be again interlocked by minute hooklets. Each barb with its barbules is thus itself like a little feather. In the ostrich family the barbs, though possessing barbules, are free, and the familiar loose plume results. In a great many birds the quill bears a second shaft, rising at the base of the vane. This is usually small, but in the cassowaries and a few other birds main shaft and 'aftershaft' are almost equal, and the feather is thus distinctly double.

Fig. 1.—Feather from the back of *Argus gyantius*:

base the quill is partly imbedded in a small sac of the skin, and shows at the very end a small aperture for the entrance of the nutritive vascular pulp. The barbs or small plates, which together form the vane, are linked together by pointed lateral barbules, which may be again interlocked by minute hooklets. Each barb with its barbules is thus itself like a little feather. In the ostrich family the barbs, though possessing barbules, are free, and the familiar loose plume results. In a great many birds the quill bears a second shaft, rising at the base of the vane. This is usually small, but in the cassowaries and a few other birds main shaft and 'aftershaft' are almost equal, and the feather is thus distinctly double.

Relation to the Skin.—Only in a few birds—e.g. the ostrich tribe and the penguins—do the feathers occur all over the surface; usually they are restricted to 'feather-tracts' between which the skin is bare or at most downy. Each feather is imbedded in a sac, readily obvious on a plucked bird, and with this sac are associated muscle fibres, more or less abundant, serving to erect the feather. Unlike hairs, feathers have no sebaceous

glands associated with them; they are, however, anointed by the secretion of the 'green-gland' on the tail.

Kinds of Feathers.—The most conspicuous feathers clothing a bird are such as have been above described—'contour feathers,' or *pennæ*. Among these, however, there are down-feathers or plumes, in which the barbs remain soft and free from one another. These are the first feathers, for a time abundant on young birds, but gradually for the most part ousted and replaced by the ordinary forms. Besides these are still simpler and smaller feathers with a long shaft and a rudimentary brush of barbs—the 'filoplumes.' In addition to these common forms there are numerous peculiar modifications of restricted occurrence. Thus, in herons and some other birds small down-feathers occur, 'the summits of which break off into a fine dust or powder as fast as they are formed,' and give rise on certain parts of the skin to 'powder-down patches.' In many aquatic birds an almost fur-like down is very common, the minute component feathers having only a slight development of shaft. In great contrast are a few strong quills on the cassowary's wing, where the long shaft is quite destitute of barbs.

Development.—The cells of the under-skin or dermis multiply and push out the epidermis into a papilla. As the papilla elongates into a cone, its

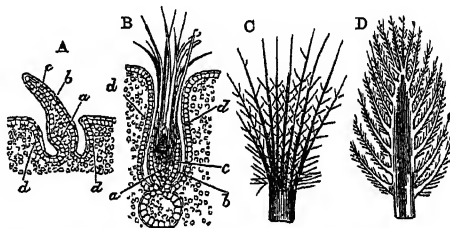

Fig. 2.—The Development of a Feather (from Wiedersheim and Parker, mainly after Studer):

A, an early stage of the feather papilla and follicle; B, the papilla breaking up into a tuft of barbs; C, the quill and primary rays or barbs, with indications of barbules; D, the thickening of one of the rays to form the stem of the vane. a, pulp of dermis; b, outer or horny layer of epidermis; c, inner or Malpighian layer of epidermis; d, feather-follicle

base sinks and becomes surrounded by a moat-like depression, the feather-follicle or sac. The core of the cone, consisting of dermis, is a nutritive pulp; the sheath of the cone, consisting of epidermis, forms the feather. But here as elsewhere the epidermis has two layers—an outer or horny, an inner or Malpighian stratum (see **SKIN**). The inner layer forms the real feather; the outer layer is only a protective sheath which is eventually shed. 'The cells of the Malpighian layer multiply rapidly, giving rise to a series of radial folds along a central axis, which extend inwards towards the pulp, and are externally bounded by the horny layer. These folds then become cornified and separated from the surrounding cells, and by a gradual drying of the central pulp-substance give rise to a tuft of horny rays, which are, however, at first bound together by the enclosing outer layer.' After hatching, the sheath is shed and the barbs set free; the undivided lower part remains as the quill; the barbs develop barbules; the result is an embryonic down-feather.

The more permanent feathers have an essentially similar history. From the base of the first follicle a second is formed; the growing papilla within the latter ousts the embryonic feather and replaces it; one of the rays formed as above described 'becomes rapidly thickened, and forms the main axis or

stem, to which the barbs are attached on each side. The result is an ordinary penna or contour-feather.

Growth and Shedding.—When in process of formation, feathers are of course genuinely alive; the vascular nutrient core of dermis keeps up the supply. They grow with great rapidity, and in some birds attain a length of more than two feet. When fully formed, however, the pulp dries and shrivels, and the feathers become virtually dead from tip to base. They usually last only one year, being replaced by a fresh growth, which generally occurs at the end of the reproductive period. This process of moulting is in a general way equivalent to the 'skin-casting' of reptiles and the shedding of hair in mammals, but its physiology is not yet understood. Involving no little expenditure of vital energy, generally occurring after the already severe strain of reproduction, brooding, and parental care, moulting is frequently associated with mortality, but when successfully accomplished is obviously of great advantage in repairing the injuries of the past and in equipping the birds afresh for migratory flight or the ordinary business of life (see BIRD).

Colour.—Feathers excel hairs and scales in the richness and variety of their colouring. This is usually most prominent in the male birds, but is emphasised in many cases only when sexual maturity is attained. Very often the bright colouring is acquired along with other decorations in a spring moult before the breeding period. The colour is due to the presence of pigment, but is greatly enhanced by physical peculiarities, such as markings on the barbs and the occurrence of air-spaces (see PIGMENT).

In regard to the general physiology of feathers but little can be said. Their utility as a clothing for the skin and as organs of flight is evident enough, but the conditions determining the historic and individual development of these most highly-evolved skin-structures are quite obscure. It is noteworthy, however, that this climax of integumentary outgrowth occurs in animals living a very active life, with the highest body-temperature, and with peculiarly thin skin almost devoid of the usual glands.

Industrial Uses.—Feathers are still largely used as Quills (q.v.) for writing, for holding the sable hairs of artists' brushes, and for toothpicks. Much more important is their use for stuffing beds, quilts, and cushions, when dried and cleaned; the feathers and down of the Eider-duck (q.v.) being most highly esteemed, and after them those of geese, swans, and poultry. The feathers of most kinds of birds are used for personal ornament, often after being washed, bleached, dyed, curled, or made up. Ostrich (q.v.) feathers are the most notable for ornamental purposes, and it is for its feathers alone that it is reared. Other feathers for various kinds of ornament are those of the American ostrich or rhea, adjutant, bird of paradise, humming-bird, albatross, grebe, and penguin (see the articles on these various birds). An Act of 1921 forbade importation of plumage of any bird except the African ostrich, the eider duck, and birds ordinarily used for food, with special arrangements for feathers wanted for scientific purposes.

Feather-stars. See CRINOIDEA.

Featherstone, an urban district in the West Riding of Yorkshire, $\frac{2}{3}$ miles S. by W. of Pontefract. In a riot here arising out of a coal strike (1893) the military were called out, and two men

were killed and six wounded—the subject of a royal commission. Pop. 15,000.

Febris Diaria. See EPHEMERA.

Febronianism, a system asserting the independence of national churches, propounded (1763) by Hontheim (q.v.), under the pseudonym 'Febronius.'

February, the second month of the year, contains in ordinary years 28 days, but in leap-year it has an intercalary day. On the 15th was held the *Lupercalia* (q.v.) or *Februa*. See CALENDAR, MONTH.

Fécamp, a manufacturing town and seaport in the French department of Seine-Inférieure, is situated in a narrow valley, flanked on either side by steep cliffs, at the mouth of a little stream, 28 miles NNE. of Havre by rail. The great Benedictine abbey church (c. 1220) in the Early Pointed style, rich in painted glass, monuments, and carved woodwork, was burnt in 1892, and rebuilt and consecrated in 1895. At Fécamp the benedictine liqueur, formerly made by the monks, is still produced in large quantities in a factory. The new harbour, opened in 1892, is frequented by colliers from Newcastle and Sunderland, by Baltic timber-ships, and by fishing-vessels. Fécamp's industries include fish salting and smoking, tanning, corn and oil milling, net-making, and cotton-spinning. Population, 17,000.

Fechner, GUSTAV THEODOR, one of the founders of psychophysics, the science of the relations between the mental and the physical sides of man's nature, was born at Gross-Sarchen in Lower Lusatia, 19th April 1801. After studying physics at Leipzig, he became professor of the sciences comprehended under that name in the same university in 1834, his labours being principally devoted to galvanism, electro-chemistry, and the theory of colour. Five years later, however, in consequence of a disease of the eyes, he abandoned these branches for that of philosophy and psychophysics. His most important book on this subject is *Elemente der Psychophysik* (2 vols. 1860), whilst on galvanism he wrote *Massbestimmungen über die galvanische Kette* (1831), and brought out an enlarged translation of Biot's *Handbook of Experimental Physics* (5 vols. 1828–29). Besides these he wrote some books on belief and on the soul, and under the pen-name of Dr Mises published a number of smaller miscellaneous works, including a volume of *Humorous Essays* (1824) and another of *Poems* (1842). In *Mind* for 1876 will be found a paper on Fechner's psycho-physical law by James Ward. Fechner died 18th November 1887.

Fechter, CHARLES ALBERT, an actor of eminence, was born in London, 23d October 1824, his father being a Frenchman of German extraction, his mother an Englishwoman. When only three or four years old he went with his parents to France, and was there educated as a sculptor. His predilections were, however, in favour of the stage; and, making his *début* in 1840, he soon became a popular actor. In 1860 he appeared in London with great success in an English version of *Ruy Blas*, and next year astonished Londoners by his powerful impersonations of Hamlet and of Othello, departing widely from stage traditions. Subsequently Fechter became the lessee of the Lyceum Theatre, playing the chief part in most of the pieces produced. In 1869 and 1872 Fechter paid visits to the United States, where he thenceforward remained. He was not successful as a manager in Boston. He died at his farm near Quakertown, Pennsylvania, 5th August 1879.

Fecundation. See FERTILISATION.

Federalists, a political party formed in the United States in 1788, whose members claimed to

be the defenders of the constitution and of the federal government, in opposition to the Republicans or Democrats (q.v.), whom they dubbed Anti-federalists. Washington, John Adams, Hamilton, Jay, and Marshall were leaders. Its fate was sealed by the holding of the Hartford Convention (q.v.), and by 1820 it had disappeared.

Federated Malay States. See MALAY STATES.

Federations and Unions.—Federation, in modern political terminology, denotes that form of political organisation in which a number of units of government, while retaining for certain purposes their separate identity, for other purposes are merged in a larger whole, whose personality is a new entity different from the mere sum of the several units put together. It differs from a unitary form of government in that the functions of government are divided between the central government and the states or provinces of which the whole is made up, in such a manner that the distribution of powers is not dependent on the will of either the central or the provincial governments. In a unitary state it is often necessary or desirable, for reasons of practical convenience, for the central legislature to accord to inferior bodies legislative authority; but in that case the power which conferred can take away, and there is no real federal element. The contrast is well illustrated by the case of the Union of South Africa, which contains in its constitution certain federal elements, and which was drafted by men who originally had proposed to bring about nothing more than a federal union. While under the terms of that constitution the provinces have a certain sphere of action, their legislation is subject to the paramount authority of the Union Parliament, and that parliament can, under certain not very difficult conditions, actually abolish the whole provincial constitutions. On the other hand, a federation differs from a mere alliance in that an alliance gives no more than a sum of parts, while federation creates a new organic unity. In entering upon an alliance a state diminishes in no degree its sovereignty, though it may agree to limit its exercise in certain ways, as, for instance, did Great Britain, France, and Russia in agreeing in 1914 to make no separate peace with their opponents, or as did the powers who agreed in 1919 to form the League of Nations; but in entering a federation a state parts irrevocably with a portion of her sovereignty, and, unless she stipulates for the right to withdraw, is bound to remain a member of the federal whole, as the northern states of the United States showed in the war of secession.

For the rise of a federation two conditions are necessary: in the first place, there must be communities of an organised type, which, through reasons of proximity, race, language, religion, common interests, or other such ground, are anxious for some closer union among themselves; and, in the second place, that anxiety must not be strong enough to lead to willingness to unite in the fullest sense. History shows that federation is normally formed between communities which have, prior to the agreement to federate, either been united in alliance, or have formed part of a territory under one rule, or have fulfilled both conditions. This fact points to the conclusion that federation is a natural step towards national unity, and in fact this view is borne out by the experience of the modern federations. It is clear that the nationality of the United States is a very different thing now from what it was in 1787; that Swiss nationality has greatly developed since 1848; Germany has thrown off much of its particularism since 1871; and while local feeling is still strong

in Canada, it is infinitely less so than in 1867, when the people of the several provinces regarded one another as little better than strangers. At the same time it is clear that the growth of national feeling is not in these cases at all likely to lead to the adoption of a unitary form of government; with lessened fear of the federal government, there has come an increased readiness to extend its functions, but the value of provincial or state autonomy remains unimpaired. Federalism, in fact, shows itself as definitely adapted to reconcile within a whole deep-seated differences, such as those between Protestant and Catholic Germany, between French and British Canada, between the several elements of nationality in Switzerland, and the very varied elements which make up the population of the United States of America. On the other hand, where there is real national unity there is no possibility for enduring federalism, a fact which explains the breakdown of the suggestions that the new kingdom of Italy should take the form of federalism.

Federalism cannot, however, endure unless the national sentiment is strong enough to resist the tendency to particularism inevitable when a portion of sovereignty is retained by the states, and unless there is either no state which is so strong as to be able to seek supremacy over the whole; or, if one state has the strength to do so, that state is animated by sufficient federal spirit to refrain from such action. Federalism has often appeared in the course of history, but it has not normally shown the power to develop into a real organic unity. Thus the elements of federalism present in the two Athenian confederations were soon extinguished by the eagerness of Athens to found an empire, and the equal anxiety of the other states to assert their independence the moment they were free from immediate danger. The Achæan league, which maintained its existence from 280 to 146 B.C. with varying fortune, was prevented from regenerating Greece, partly no doubt by external interference, but in the main by the indifference of the constituent cities to anything save their own immediate interest. Similarly, in the latter part of the 18th century, the memoirs of Lord Malmesbury reveal the impotence to which the Dutch were reduced by the jealousy of the central authorities displayed by the several members of the federation; and in the 19th century the same thing can be seen in the records of the federations of South and Central America.

The immediate cause of the formation of a federation has, in the great majority of cases, been the need of protection against a common enemy. This was clearly so in the case of the Achæan league, framed to meet the Macedonian efforts to control Greece, of the United States of Holland, of Switzerland, of the United States of America, and the South American federations, and even of Germany. In the case of Canada, also, there is evidence that the possibility of friction with the United States was present to the minds of the framers of the Dominion. Even in the case of the Commonwealth of Australia considerations of defence had some influence in inspiring the movement to closer union, but that motive had probably far less weight than other arguments more directly commercial in character. Indeed, the tardiness with which the Commonwealth came into being is one of the clearest proofs of the long-continued freedom of its inhabitants from anxiety on the score of external aggression.

As the essence of a federation is the creation of a new entity with defined powers which is to subsist alongside of the former political units, while the latter are to lose certain of their former authorities, it is practically essential that the agreement

creating the federation should be in writing. This is certainly the case with all the federations existing at the present day, but it is uncertain whether it was the case with the constitution of the Achæan league, though it is possible that in some instances at least when a new city was admitted to that league the terms of admission were duly recorded. The form of these instruments varies in the different cases, but in all they embody what are in effect the terms of treaties made among the contracting parties; even in the case of the constitutions of Canada and the Commonwealth, while the instruments themselves are acts of the Imperial Parliament, the terms contained represent the results of the agreements of the representatives of the several provinces and states. But, of course, it is possible for provision to be made in the constitution, as is made in those of the United States and Canada, for the erection of new states or provinces out of territories which have never enjoyed an independent political existence in any form.

Not only must the constitution be written, but it must also be rigid, and must in some manner be superior to the organisation which it creates. It is, indeed, conceivable that a constitution might be framed for a federation which should be absolutely rigid, and which should never admit of change, but no such constitution has yet been recorded. Without exception, all modern federations provide for the alteration of the constitution in a special manner which removes it from the ordinary legislative competence of either the central or the aggregate of the provincial legislatures. Further, the constitution must provide for a division of the authority between the central and the provincial governments, and probably it must provide some means by which these authorities may be kept within the bounds assigned to them by the terms of the constitution. But within these limits there is room for the greatest possible variations in the nature of federal governments, according to the different degrees of freedom allowed to the members of the federations as against the central government.

Of the individual federations, the Achæan league deserves special mention as the first recorded federation of considerable duration and importance. Unfortunately we know little of the terms of its constitution. There was, however, an assembly, composed of the whole body of citizens of the league who cared to attend, which decided the issues of war and peace, provided means for carrying on war, determined questions as to admission of new members of the league, and elected the federal executive, consisting of a strategus and a body of *demurgi*; the federal principle was recognised in the fact that the voting was by cities, not by numbers of citizens. There seems, also, to have been a federal council, and Polybius records that the unity of the members of the league extended to the use of the same coins, weights and measures, and judges, a remark which suggests some form of federal judicature. It is, however, uncertain whether the individual states were secured against encroachment by the central power, even *de jure*, and *de facto* it is clear that the constitution was by no means strictly observed, even in the best days of the league.

The true federal character of the Achæan league, however, showed itself in the effort which it made to secure that in political matters the whole league should act as one unit, and that no separate negotiations with other states should be allowed. This principle is expressly laid down in the constitutions of the United States and Germany; and, in the case of Canada and Australia, while the power of making treaties rests formally with the government of the United Kingdom, all matters affecting treaties are reserved to the central governments. In the

case of Switzerland, however, the cantons may, in exceptional cases, conclude treaties with foreign countries regarding matters of vicinage, public economy, and police, although foreign policy and the general treaty power rest with the federal government; and in Germany the states may, with the consent of the federation, conclude agreements with foreign powers on matters regulated by state legislation. But, though in the United States the control of foreign affairs rests with the federal government, there is no provision in the constitution which secures to that government the ability to enforce directly the performance of their obligations by the states of the Union; and, in point of fact, difficulties have arisen through the absence of such a power; in Germany also the federation's powers seem to be limited; the constitution of Canada, and that of the Commonwealth, therefore, accord the power to provide by legislation for the carrying out of the treaty obligations binding on the Dominion and the Commonwealth.

In the modern federations great stress is laid on the creation of a common nationality, and the conferring upon the citizens or subjects in each of the component parts of the federation of the full rights of citizenship in that part. This is common to all the great federations, and its stands in striking contrast with the provisions of the constitution of the Union of South Africa, which do not even provide for freedom of migration throughout the Union. Unfortunately we do not know how far in the Achæan league mutual rights of citizenship were accorded by the several cities; but tradition ascribes to the old Latin federation, before its absorption by Rome, the rule that full commercial rights and rights of intermarriage were possessed by the citizens of the several towns comprised in the league.

In the Achæan legislature the federal principle received recognition in the fact that the voting was by cities, not individuals; and in modern federations this principle is also regarded, but it is modified by the rule that legislatures should be bicameral. Thus, in the upper house the representation is now federal—i.e. each state has a definite representation—while in the lower chamber the representation is by population. In the more perfect form of federation, as in Switzerland, the United States of America, Australia, and in a modified form in the Union of South Africa, the number of representatives of the states in the upper house is the same, despite the differences of size and importance between the states. In the case of Canada, as of Germany, the numbers are determined by other considerations; the aim, in the first case, being to secure the equality of Ontario and Quebec, and in the latter to safeguard without unduly emphasising the importance of Prussia. Australia and Germany have full provisions to solve the case of deadlocks between the representatives of the people and of the states.

In the distribution of powers between the federal and provincial legislatures great variety exists, but Canada is singular in adopting, in deliberate differentiation to the practice in the United States, the rule that the federal legislature should possess whatever legislative authority was not expressly given to the provinces, the normal rule being that the federal legislature has only the authority which is expressly given to it. The importance of the distinction may be over-estimated, for, in the case of Germany and the United States, at least, judicial interpretation has extended widely the powers of the central legislature. As a rule the federal and state legislatures have concurrent authority over a large number of subjects, federal legislation prevailing over state legislation. Broadly speaking, the subjects ascribed to the central authority

include nationality, foreign affairs and treaties, colonial affairs, the army and navy, customs duties and internal free trade, posts and telegraphs, weights and measures, the currency, patents and copyright, bankruptcy, and the mercantile marine, all being matters of obvious national importance. But even in regard to these matters there are divergences: the control of the Swiss and United States armed forces is, in effect, divided between the central and the provincial authorities; and it is only in the case of Germany, Canada, and Australia that the full control of military matters rests with the central government alone. Similarly, Switzerland alone has full powers over all railways, though in each case some authority is conferred on the federation in respect of these important adjuncts of military operations, and in Germany the federation is required to assume ownership of the railways serving for general traffic and to manage them on a uniform system.

In no case have the state or provincial authorities any direct control over federal legislation, and, conversely, the federal authorities in Switzerland, the United States, Australia, and with one exception in Germany, cannot directly affect state legislation. Canada, however, permits the executive government of the federation to disallow any provincial act within a year of its passing, and the same power in an extended form is accorded in the unitary constitution of South Africa.

In the executive government the federal principle is disregarded entirely in practice, at least, in the United States; in Germany the ministers are required to keep the Reichsrat, which represents the states, in touch with federal affairs; and in Canada and Australia it presents itself in the form of the convention, that a cabinet should represent all the provinces and states. In Switzerland each of the seven members of the Federal Council must be chosen from a different canton; moreover, the members of the council are elected by the Federal Assembly, but hold office for a fixed term of three years, thus occupying a position half-way between the purely parliamentary executives of the British federations and the elective presidency of the United States.

The necessary conflict of authorities, which is part of the nature of a federation, requires as its logical complement a judiciary to settle the limits of power on either side. Such a judiciary has been created in the Supreme Court of the United States, which forms an essential part of the constitution. Similar services have been rendered for Canada, not so much by the supreme court of that dominion as by the judicial committee of the Privy Council, and for the Commonwealth by the high court, whose existence is provided for in the constitution, and from which, save by its leave, no appeal lies to the judicial committee on matters affecting the constitutional rights of the Commonwealth, and the states or of the states *inter se*. But in the case of Germany and Switzerland, while the federal courts have the right and duty of pronouncing invalid provisions of state or cantonal law, they are debarred from questioning the validity of a federal law, though they may determine the extent of its application. There is, however, in each case a special reason for this lack of power; a Swiss federal law may be annulled by the use of the referendum on the demand of 30,000 citizens or eight cantons, while in Germany the composition of the federal council gives some measure of security against the passing of any law which really threatens state interests. The German supreme court is empowered to decide constitutional controversies between states, or the federation and a state, and the Commonwealth high court has a similar authority.

Practically essential, in view of the rigidity of the constitution in a federation and the rule of law, is the power to amend the constitution. This right is, indeed, denied to Canada, but the deficiency is made good by the power of the Imperial Parliament, which is exercised in accordance with the expressed will of the people of Canada, ascertained in such manner as seems in each case appropriate. In Australia change requires the assent of a majority of the people and a majority of states, but the reference to the people may take place even if the proposed change has been approved by one house of Parliament alone. In Switzerland any change must be approved by a majority of the citizens and of cantons, and a power of initiative is given to not less than 50,000 voters. In the United States, in practice, revision is effected by majorities of two-thirds in either house of Congress, and ratification by three-quarters at least of the states; and, in recent years, the procedure seems to have become more easy to work. In the German federation a constitutional change may be effected by simple law passed in the Reichstag by a two-thirds majority of those present, who must be at least two-thirds of the legal total of members, but the interests of the states are secured to some extent by the right of the Reichsrat to demand an appeal to the people. On the other hand, the alteration of their own constitutions is a privilege of the states or provinces, subject only to a limited degree of control; thus, in the United States, the federation can only recognise a republican constitution; in Germany a state constitution must be republican, the government must be responsible to the legislature, and there must be universal, equal, direct, and secret suffrage on the principles of proportional representation; in Switzerland a constitution must not contravene the federal constitution, must be republican, must have been accepted by the people, and be open to revision when demanded by a majority of the people; and, in Canada, the federal government can disallow any law altering the provincial constitution, just as it can disallow any other law. The duty of maintaining these constitutions against internal tumult rests primarily with the local governments, but the federal authority is in each case bound by law or practice to intervene where its aid is applied for, at least if it considers that there is real need for its services.

No provision is made in the Swiss constitution for the expansion of the number of the members of the federation, but such provision is made in the case of the United States, Germany, Australia, and Canada.

The fundamental distinction between these true federations and the constitution of the Union of South Africa, which, in many respects, has a federal aspect, is due to the fact that the authority of the Union Parliament is ultimately paramount. The Senate is, indeed, as regards 32 of its 40 members, representative of the old colonial legislatures, and therefore to some extent may be deemed to stand for provincial rights; but parliament may, after the expiry of ten years, alter its constitution, and the provisions for a joint session in the case of deadlocks secure that the will of the lower house, which is based on population, alone shall prevail. There is, again, a definite allocation of a legislative sphere to the provinces, but the Union Parliament has paramount legislative authority on the same subjects, which is totally contrary to a federal system. Again, the central government cannot merely veto any provincial act; no such act can become law without their assent. Further, the executive government of the province can be influenced largely through the administrator, who is a servant of the central government, and who takes an active share in administration, while the

provincial finances are ultimately under the control of the administrator and the auditor, who is also a servant of the central government. Finally, the parliament can abolish the provincial legislatures by a simple act, subject only to the requirement that such an act must be reserved for the signature of the king's pleasure. Nor are these theoretic powers; the short history of the Union has sufficed to show that the central government are determined not to allow the provincial rights to approximate to those of federal states. The relation between Great Britain and Northern Ireland under the Government of Ireland Act, 1920, is more truly federal. The Imperial Parliament, it is true, retains power to legislate for Northern Ireland on any topic and to alter its constitution, while the bills of the Irish legislature may be refused assent at the discretion of the Imperial Government. But it is clearly intended in practice not to interfere, except in the case of the utmost necessity, with the free exercise of the legislative and executive functions of the Irish Parliament and Government, whose powers are very far-reaching. The constitution accorded to India in 1919 is preparatory to the evolution of a true federation, which is demanded by the racial and linguistic divisions of India, but in itself it is lacking in essential federal characteristics.

The merit of federation lies in the fact that it is often the highest form of political unity of which a community may be capable, especially in cases where there are divergencies of race or religion among the inhabitants, and that in large countries government by semi-sovereign authorities tends to attract to public life abler men than would be attracted by the performance of functions merely delegated. Its demerits are essentially the outcome of its qualities. The division of powers tends to weaken both the central and the state or provincial authority, and to afford the possibility of the obstruction of reforms through legal difficulties. The same defect appears in the tendency of federations towards conservatism, which has evoked many complaints in the United States, and which has induced the Labour party in Australia to advocate the reduction of state powers with a possible adoption of a unitary constitution. Nor, of course, is federalism a success in any country where respect for law is not strongly developed; hence the comparative failure of the system, except in the case of Germany, Switzerland, the United States, and the British federations of Canada and Australia.

Fee; Fee-simple and Fee-tail. The term fee is derived from *feudum*, a feudal holding; but in English law it has now no reference to tenure; fee means an estate of inheritance in land. The person who has the fee is entitled not only to the annual profits, but also to the corpus of the land; he may sell or otherwise dispose of it, and he may commit acts of waste, which impair its permanent value. If he dies owner in fee, the land will go to his heirs or to the person entitled under his will (in legal phrase, the devisee). If a man holds 'to him and his heirs,' he is owner in fee-simple; he has the largest estate known to the law. But a fee-simple may be made *determinable*, as if land be given 'to A and his heirs, lords of the manor of Dale;' in this case, if A or any of his heirs ceases to be lord of that manor, the estate, and all interests derived from the owner of the estate, will come to an end. A fee-simple may also be made *conditional*, to vest only on the happening of an event. In early times, if land was given 'to A and the heirs of his body,' or 'to A, if he shall have an heir of his body,' the judges held that the fee was conditional; as soon as the condition was fulfilled (as soon, that is, as a child was born to A), the donee became owner in fee-simple, with full power to alienate the estate.

In 1285 the lords and great men of the kingdom procured an act, commonly known as the statute *De Donis Conditionalibus*, whereby it was provided that in such cases the land should descend to the heirs of the body, according to the term of the gift. The statute therefore restricted the right of alienation, and limited the succession to a particular class of heirs. An estate given with words limiting it to heirs of the body was therefore called a fee-tail (*taillé*, 'cut down or limited'). The strict rules of the statute remained in force until means were devised for breaking entails. See **ENTAIL**. It is to be observed that, when heirs are mentioned in conveying an estate, the heirs themselves take nothing directly; thus, an estate given to A and his heirs means simply an estate of inheritance given to A. If land be granted to A and his heirs in trust for B and his heirs, the legal fee is in A the trustee, and the equitable fee in B the beneficial owner. An estate in fee might always be given by will without the addition of the word 'heirs'; and now, by the Conveyancing Act, 1881, it is no longer necessary to use the word 'heirs' in any deed, it being sufficient that the conveyance is 'in fee simple.' In Scotland the term *fee* is used as a correlative to *liferent*, to signify the ownership of land or money. In some cases the fee is vested in a person whose beneficial interest does not extend beyond his life; his 'fiduciary fee' corresponds to the 'legal fee' of English law.

Feeble-mindedness. See **IDIOCY**.

Feeling. See **EMOTION**, **PSYCHOLOGY**, **TOUCH**.

Fees. Neither a barrister nor an advocate can take legal proceedings against his client for the recovery of his fees, even under a special contract. It is clearly established that 'the relation of counsel and client renders the parties mutually incapable of making any legal contract of hiring and service concerning advocacy in litigation' (13 *Common Bench Reports*, N.S., p. 677). There is nothing, however, to prevent an advocate recovering fees earned by him, by the exercise of his professional knowledge where the relation of counsel and client did not exist between the contracting parties—e.g. by acting as arbitrator or returning officer. There is some, but not strong, authority for the proposition that an express promise to pay fees might be enforced by a barrister against a solicitor who had actually received them from the client. On the other hand, a solicitor is entitled under his general retainer to employ and pay counsel; and fees so paid can be recovered by the solicitor from his client, or from an unsuccessful adversary. No action lies to recover back fees given to a barrister to argue a cause which he did not attend. Special pleaders, equity draftsmen, and conveyancers who have taken out certificates to practise under the bar, and are not therefore counsel, may recover their reasonable charges for business done by them. Barristers' and advocates' fees are paid before being earned. This rule, by removing from members of the bar all pecuniary interest in the issue of suits, has done much to maintain its independence and integrity.

In the United States the two branches of the legal profession are not separated as in England. A barrister is entitled to recover his fees, and is liable to be sued for professional incompetency or negligence. Nor is there anything illegal or improper in an American counsel agreeing to let the payment of a fee by a poor client depend on the issue of his action.

In France an action by a barrister for his fees is maintainable, but in most of the French bars such a proceeding is rigorously discountenanced, and in Paris it would lead to disbarment. The fees of French advocates are now usually paid in

advance, and any bargain between an advocate and his client which made the amount depend upon the issue of an action would be regarded as most dishonourable.

The theory that an advocate's services ought to be given gratuitously arose at Rome. To defend his client was one of the duties incumbent upon a patron, and it was all the more readily and faithfully discharged when forensic eloquence was perceived to be an avenue to political power. The Cincian law (204 B.C.), in which the receipt of pecuniary reward by an advocate was simply prohibited, gave expression to the prevalent public feeling upon the subject at this time. The Cincian law was first systematically evaded, and was then practically repealed by a decree of the Emperor Claudius, which limited the maximum fee which an advocate might receive to 10 sesteritia (about £78). The old Roman idea that the gifts of eloquence and persuasion should not be sold has made itself felt in the restrictions imposed by law or custom upon an advocate's power to bargain for fees or to secure their payment.

By the common law of England, a physician could not recover his fees by an action at law; but this rule was repealed in 1849.

The members of the inferior branches of both professions, such as solicitors, apothecaries, and dentists, have never been prevented by any rule of law from taking legal proceedings for the recovery of their charges.

Fehrbellin, a town of Prussia, with 2000 inhabitants, 40 miles NW. of Berlin by rail. Heie on 28th June 1675 the Swedes under Wrangel were disastrously defeated by the Great Elector. A tower (1875-79) marks the battlefield.

Feisul. See FAISAL.

Feith, RHIJNIS, a Dutch poet, was born 7th February 1753, at Zwolle, in Overijssel. He studied law at Leyden and settled in 1772 at his native place, of which he became mayor in 1780, and where he died on 8th February 1824. Feith tried almost all kinds of poetry. In 1792 appeared *Het Graf* ('The Tomb'), a didactic though sentimental poem; in 1802, *De Ouderdom* ('Old Age'); in 1796-1810, four vols. of lyrical pieces marked by a high enthusiasm and warmth of feeling. Of his tragedies the best known are *Thirza* (1784), *Johanna Gray* (1791), and *Ines de Castro* (1793). Of Feith's prose works the most important are his *Brieven* ('Letters on Different Subjects', 6 vols. Amst. 1784-94), which by their polished style and refined criticism did much to improve the literary taste of Holland. His complete works (1824) fill 11 vols.

Felaniche, or FELANITX, a well-built town of the island of Majorca, is situated in a mountain-girdled valley, which produces wine. Boots, shoes, baskets, water-jars, and brandy are made, and wine is exported. Pop. 12,000.

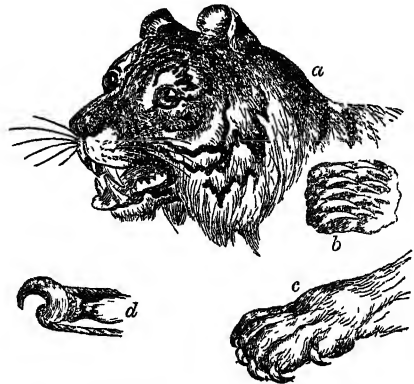

Félegyháza, a town of Hungary, 80 miles SE. of Budapest by rail, with trade in grain, fruit, wine, tobacco, and cattle; pop. 37,000.

Félibre (from *sét félibre de la loi*, perhaps 'seven doctors of the law'). See MISTRAL, PROVENÇAL.

Felidæ, a family of carnivores in the digitigrade or aluroid section, corresponding to the genus *Felis* of Linnæus, and to what we commonly call the cat tribe. They include the most carnivorous of Carnivora, excelling the less specialised forms, just as falcons and eagles are in a similar direction more perfect than many other less predacious birds. Their chief characteristics of habit and structure may be taken together, being obviously complementary.

Conspicuous for their muscular development, they express this most characteristically in the sudden leaps and bounds to which they trust after

stalking their prey with all the cunning of true hunters. They crawl stealthily on noiseless, velvety paws, or patiently lurk for passing victims; at the fit moment occurs a sudden, almost explosive, outpour of reserved energy, a great bound, a yell inspiring terror, a blow or two with the powerful forelimbs, and the sharp canines and sharper retractile claws begin their murderous work on the struggling prey. With the exception of the lion, the Felidæ are more or less arboreal, and make good climbers.

Characteristic Features of the Felidæ :

a, tiger's head; b, portion of tongue; c, right fore-paw, showing claws; d, claw, showing tendons. For dentition, see article CARNIVORA.

The body is rather long, and very lithe and graceful; the limbs are rather short, except in cheetahs and lynxes; the tail varies from a long appendage to a mere stump. They are the most digitigrade of carnivores—i.e. they walk on the tips of their (five) fingers and (four) toes. Under a glove of velvet they have claws of iron—strong, much curved, very sharp, and retractile; withdrawn by special muscles and ligaments into sheaths when not in use, and their points even turned upwards, so that they are not blunted by unnecessary friction, and do not interfere with the movements of the animal by hooking objects which are in the way. The collar-bones or clavicles, though unattached to shoulder or sternum, are better developed than in other carnivores.

The Felidæ never bury or store their dead prey, but often drag it off to some place of shelter, and in so doing exhibit enormous strength. The leaps a lion can take with a mouthful half as big as itself are herculean marvels. Besides the strength of grip, the powers of rending and mastication are equally well developed. Thus, we find a skull which tends to be short, broad, and rounded, with large posterior ridges for the fixing of muscles, and with a wide cheek (zygomatic) arch in which lie the relatively enormous muscles working the jaws. The latter form powerful short levers, and the articulation is such that only an up and down, and no rotatory, motion is possible.

The teeth are well adapted for their work, the chief features in the dentition being the large size, strength, and sharpness of the canines, and the two specially adapted cutting teeth ('carnassials' or 'sectorials')—viz. the last premolar above and the single molar below, which are both compressed into sharp blades. The front teeth are relatively small, and so, but more markedly, is the molar on the upper jaw. The numerical relations of the teeth may be summed up in the formula $\frac{3131}{3121} = 30$. The well-known character of the tongue, most conveniently exemplified in the cat,

is also to be associated, as far as utility is concerned, with the carnivorous diet. It is thickly covered with sharp, recurved, horny papillæ, strong enough to rasp off the skin and draw blood from the hand, and obviously useful in clearing the flesh off the bones of victims. As is usual in carnivorous animals, the cæcum of the intestine is small and simple. The food varies widely, from the large ruminants attacked by lions and tigers to the mice for which cats hunt. Some of the large forms are said to develop a special partiality for human flesh; some of the smaller do not disdain to eat big insects. In attack the Felidæ often exhibit a wise discretion in seeking to avoid a fair fight with large animals.

Many members of the family have exceedingly beautiful fur, soft and glossy in texture, generally striped and spotted according to the varied pigmentation of the hairs. The markings in some may be regarded as protective; thus, the stripes of the tiger 'assimilate,' according to Wallace, 'with the vertical stems of the bamboo,' and the spots of the leopard are suited to the interrupted light of the jungle. It seems also true, as Eimer has emphasised, that the markings illustrate definite rhythms of development, and exhibit an orderly progression both in the individual and in a series of related forms. They are in fact, here as elsewhere, external indices to constitutional changes. The colour-differences between the sexes are seldom marked, though they are distinct in the Ocelot (*Felis pardalis*) and a few other forms. The male lion, stronger and larger than the female, is distinguished by his mane, which appears to have protective as well as decorative value. The male Canadian Lynx (*F. canadensis*) also excels his mate in the development of a ruff round the neck. The Felidæ are very cleanly, taking pains to keep their fur in order, and are free from unpleasant smells. They have, however, a notorious dislike to water.

As one would expect from their habits, the senses of Felidæ are highly developed. Keen scent; quick sight, especially for near objects, and well suited for night-work; acute hearing, and great power of localising sounds; and a delicate tactile sensibility in the strong hairs of the moustache or whiskers, are characteristic. The eyes are large, and possess marked powers of accommodation to different quantities of light; the pupillary opening is rapidly altered, contracting in bright light to a narrow slit, though in some forms into the usual circular shape. The animals generally hunt at night, and then their eyes seem to 'burn brightly.' The ears are of moderate size, usually pointed, and mobile.

The intelligence of the family is certainly highly developed, and many of the members can be readily tamed when young, though a deeply ingrained wildness keeps the domesticated cat or tamed individuals of other species from exhibiting the marvellous educational results familiar in dogs. They are not social animals, never hunting in troops, and even the males and females usually live apart except at the breeding season. In spite of the individualism and ferocity of the Felidæ, maternal care and affection are exhibited in a high degree. Not only will a lioness robbed of her cubs risk her life to rescue them, but the habitual care is tender and lavish.

The wild Felidæ seem to be less prolific than the Canidæ, two or three at a birth being an average number. There are usually eight teats, lying on the breast and the abdomen.

While the above are the chief characteristics of Felidæ, it is necessary also to notice that the family is separated from the adjacent civets (*Viverridæ*) and hyænas (*Hyænidæ*) by technical details such as the reduction of molars to one

above and one below in each jaw, the presence of only two inferior premolars, the division of the bony auditory prominence or tympanic bulla into two chambers, the number (thirteen) of dorsal vertebrae, and so on.

The Felidæ are almost world-wide in distribution, absent only from the Australian region, Madagascar, and the Antilles. They are especially abundant in warmer climates. In the Old World, Lion (*Felis leo*), Tiger (*F. tigris*), Leopard or Panther (*F. pardus*), Ounce (*F. uncia*), Wild Cat (*F. catus*) are well-known species; while in the New World may be noted the Puma (*F. concolor*), the Jaguar (*F. onca*), and the Ocelot (*F. pardalis*). The Lynx (*F. lynx*) is probably common to both hemispheres. The Cheetah or Hunting Leopard is sometimes placed in a separate genus, *Cynælurus*.

Numerous Felidæ occur in Tertiary strata, many quite like species now alive, others with more numerous and less carnivorous teeth, others again (e.g. *Smilodon*, *Machærodus*, and especially *Eusmilus*) with much greater development of upper canines than in modern forms. Through extinct American genera like *Nimravus*, Professor Cope traces back the modern Felidæ to a race of primitive unspecialised cats. So far as natural selection means the destructive elimination of one animal by another, the Felidæ must rank high as agents in the process, and it is at least certain that their abundant presence must exert an often wholesome restraining influence on many more prolific animals. See CARNIVORA, CAT, CHEETAH, JAGUAR, LEOPARD, LION, LYNX, OCELOT, OUNCE, PUMA, TIGER, &c.

Felix, ANTONIUS, or CLAUDIUS, a Roman procurator of Judæa in the time of the apostle Paul, was a freedman of the Emperor Claudius I. and was brother of his favourite Pallas. The circumstances under which he received his appointment are related differently by Tacitus and Josephus. The latter tells us that he cleared the country of robbers, and vigorously suppressed the chaotic seditions of the Jews; but his cruelty, lust, and greed were unbounded. His wife was Drusilla, a beautiful but renegade Jewess, whom he had induced to abandon her first husband. According to Tacitus, she was a granddaughter of Antony and Cleopatra. We read in Acts (xxiv. 25) that Felix trembled as Paul reasoned of 'righteousness, temperance, and judgment to come.' He was recalled to Rome, 62 A.D., on account of the accusations preferred against him by the influential Jews of Cæsarea, and narrowly escaped the sentence of death.

Felix I.-IV., POPES. **FELIX I.** succeeded Dionysius in the see of Rome in 269. Little is known of his history, for though he has been put amongst the martyrs there is no early evidence as to the manner of his death.—**Felix II.** was the first antipope (see ANTIPOPE), being consecrated when Liberius was banished (356) for refusing to condemn Athanasius. When Liberius was restored in the following year, Felix was constrained to retire from the city. Most ancient authorities treat him as an unauthorised interloper; but he was ultimately regarded as a saint and martyr (on what evidence does not appear).—**FELIX III.** ascended the pontifical throne in 483 as the successor of Simplicius. He was a native of Rome, and of the family from which afterwards sprang Pope Gregory the Great. Immediately after his accession Felix repudiated the Henoticon or Decree of Union between the Eastern Church and the Monophysites proclaimed by the Emperor Zeno, and proceeded to excommunicate Acacius, patriarch of Constantinople, because he refused to do the same, thus originating the first disruption between the churches

of the East and West, a breach which on this occasion lasted thirty-four years. Felix died 24th February 492, and was succeeded by Gelasius.—**FELIX IV.**, a native of Benevento, succeeded John I. in 526. He was appointed by Theodorice, and failed to meet with the approval of the clergy and the people. He died in 530. His successor was Boniface II.—**FELIX V.** (antipope). See AMADEUS (VIII. of Savoy).

Felix, Sr, with his sister and fellow-sufferer Regula, the patron saint of the city of Zurich and its cathedral. Early in the 3d century he preached Christ there, and was beheaded on the site of the great cathedral. His day is the 11th September.

Felixians, a Spanish sect of the later part of the 8th century, so called from Felix, Bishop of Urgel. See ADOPTIANISM.

Felixstowe, a coast-village of Suffolk, 9½ miles SE. of Ipswich. It is named from a priory (1105) dedicated to St Felix, a Burgundian, who from 631 to 647 was first bishop of Dunwich. With a fine beach for bathing, a pier, good golf-links, and many Roman remains near by, the place has rapidly become a popular seaside resort. Pop. of urban district (which includes Walton, to the west), 12,000.

Fell (Norw. *ffjeld*, Swed. *ffjall*), the name given in Scandinavia to the bare plateaus which occur in its mountainous regions; they are destitute of vegetation, and generally lie above the snow-line. The word enters as a component into the names of innumerable mountains, owing to the fact that in their formation they have taken on the shape of a fell. Fell is also used in the north of England and south of Scotland to designate a barren hill, and indicates Scandinavian settlements.

Fell, JOHN, Dean of Christ Church and Bishop of Oxford, was born 23d June 1625, his father, Dr Samuel Fell (1534–1649), being also Dean of Christ Church, of which the boy became a student at the age of eleven. He volunteered for the king, and with Wallis and two others contrived to maintain Church of England services during the Commonwealth; at the Restoration he was rewarded by being made Canon and four months later Dean of Christ Church, royal chaplain, and D.D. He governed the college strictly, restored its buildings, reformed its discipline, and himself attended divine service four times a day. He was liberal of his money to public purposes and the necessities of poor scholars, and did much to promote learning and the advancement of knowledge. In 1676 he became Bishop of Oxford, without, however, giving up his deanery. He rebuilt the episcopal palace at Cuddesdon, and died in 1686. His works no longer concern the world, but his name lives in the well-known proverb: 'I do not like thee, Doctor Fell, the reason why I cannot tell,' usually said to be a paraphrase made by Tom Brown, when a student at Christ Church, from Martial's 'Non amo te, Sabidi,' but more likely to be rather his paraphrase of the following version of Martial in Thomas Forde's *Virtus Rediviva* (1661): 'I love thee not, Nel! but why, I can't tell.'

Fellâh (pl. FELLÂHIN), an Arabic word meaning 'tiller' of the soil, specially applied to the agricultural or labouring population of Egypt by the Turks, in a contemptuous sense, as 'yokels,' or 'boors.' They form the great bulk of the population, and are descendants of the ancient Egyptians, intermingled with Syrians, Arabs, and other races which have been converted to Islam. In their physical conformation and features they differ among themselves, those of the northern provinces of the Mediterranean being of whiter hue, while at Aswan they are almost black. They are described as of middle stature, with large skull, facial angle almost 90 degrees, oval face, arched eyebrows, deep

dark eyes, large, well-formed mouth, with rather thick lips, thin beard, short nose, large chest, small belly, arched back, and small hands and feet. Their dress generally consists of a blue or brown cotton smock and linen drawers. On their shaven head they wear the *tarbûsh*, or only a thin cotton cap, but the better-off wear a poor turban round it. The women are singularly graceful and slender, with beautiful skin (despite their tattooing) and often lovely features, and especially magnificent eyes; their dress is a single cotton smock, which they pull up over the mouth before men, and few wear the regular face-veil. They are often married at eleven years, become mothers at twelve, and grandmothers at twenty-four. The children are pot-bellied, dirty, and fly-bitten, but grow up straight, strong, and healthy. Their villages are mere groups of mud-hovels. The food of the Fellâhin consists almost entirely of vegetables, chiefly miller bread and beans, which they eat in a crude state. Even rice is too dear for them, and animal food seldom attainable. Their drink is limited to the water of the Nile and coffee, and the only luxury which they enjoy is the green tobacco of the country; yet on this diet they are robust and healthy, and capable of extraordinary labour and endurance. In their social position they are inferior to the Bedouin, who, although they will marry the daughters of the Fellâhin, will not give to them their own in marriage. They exhibit the moral qualities of the ancient Egyptians—are intelligent, docile, pliable, cheerful, and sober on the one hand, and quarrelsome, satirical, licentious, and of unbending obstinacy on the other; and they inherit the traditional hatred of their ancestors to the payment of taxes, which were formerly too often extorted by the *basinado*. Their condition has improved; and though they have been slow to understand and exercise the political rights accorded to them, many of them played their part in the movement for Egyptian independence.

Felling, an urban district of Durham, forming an eastern coal-mining and manufacturing suburb of Gateshead; pop. 26,000.

Fellowes, EDMUND HORACE, born in London 11th November 1870, studied at Winchester and Oriel, became a minor canon of Bristol and of St George's, Windsor. He has done much to make old English music accessible.

Fellows, SIR CHARLES, English archæologist, was born at Nottingham in 1799. Working in the western peninsula of Asia Minor and along the course of the Xanthus, he discovered (1838) the ruins of the city of Xanthus, formerly the capital of Lycia, and those of the ancient Tlos. Having made drawings of some of the fine remains of architecture and sculpture which he found in these cities, and copies of some of the inscriptions, Fellows returned to England, and published *A Journal written during an Excursion in Asia Minor* (1839). In the course of another visit to Lycia in 1839 he discovered the ruins of no less than thirteen cities, each of which contained works of art, and which he described in *An Account of Discoveries in Lycia* (1841). Under the auspices of the British Museum, Fellows went out to Lycia twice, in 1841–44, for the purpose of selecting works of art, and marbles and casts, from the cities he had discovered. Knighted in 1845, he died at Nottingham, 8th November 1860. Besides his *Journals*, he wrote *The Xanthian Marbles* (1843), *An Account of the Ionic Trophy Monument excavated at Xanthus* (1848), and *Coins of Ancient Lycia before the Reign of Alexander; with an Essay on the Lycian Monuments in the British Museum* (1855).

Fellowship, in a college, is a foundation which usually entitles the holder to be a member of the college, to share in its revenues and government, and, in Oxford and Cambridge, to have rooms in college, with other privileges. Celibacy was usually insisted on in old days, and life fellowships were usual. Commonly now fellowships are for a term of years, or while the fellow continues to perform specified work. In some universities, such as those of Scotland, the fellowship is a university prize for one or more years, bestowed after examination on graduates. See UNIVERSITY, OXFORD, CAMBRIDGE.

Felo de se. See SUICIDE.

Felon and Felony. The Old Fr. *felon* was derived from a Low Lat. *felo, fello, 'a traitor,'* a word of unknown origin, possibly a derivative of Lat. *fel, 'gall,'* and so connected with Gr. *cholē*, Eng. *gall*. Its original signification was supposed to be a vassal who failed in his fidelity or allegiance to his superior, thus committing an offence by which he forfeited his fee or feud. From this it came to signify traitorous or rebellious, and was gradually generalised till it reached its modern meaning. In English text-books felony is usually defined as a crime which works a forfeiture of land or goods. Treason itself, says Coke, was comprised under the name of felony, and all capital offences; also such offences as suicide, manslaughter, and larceny, 'as they submit the commitments of them to forfeitures.' At the present day it is not possible to draw any logical and consistent distinction between those crimes which are called felonies and those which are called misdemeanours. Sir J. F. Stephen, in his *History of the Criminal Law*, pointed out that the distinction is obsolete; and, if parliament should ever find time to recast the criminal law in general principles, the term will probably disappear. The general principles of American law are the same as those of English law. In Scots law the term felony has not now any special significance. See COMPOUNDING OF FELONY and FORFEITURE.

Felsite, a pale-coloured, compact, sparingly porphyritic rock composed essentially of 'felsite matter,' which appears to be an intimate admixture of orthoclase and quartz. Most felsites are devitrified rhyolites or pitchstones.

Felspar (Ger. *Feldspath*, 'field-spar'), a general term in mineralogy for the most important rock-forming group of minerals. The felspars are usually divided into two series—in one of which the minerals crystallise in monoclinic forms, and in the other in triclinic forms. They are all anhydrous silicates of alumina, containing either potash, soda, or lime alone, or two of those bases together. Thus they are often spoken of as potash-, soda-, lime-, soda-lime-felspars, &c. They have a hardness between 6 and 7—that is to say, they can just be scratched with a good penknife. Their specific gravity is about 2.6. The most important felspars are shown in the following table:

	Silica percentage
MONOCLINIC.... Orthoclase (potash-felspar).....	64.7
Microcline (potash-felspar).....	64.7
Albite (soda-felspar).....	68.8
TRICLINIC.... Oligoclase (soda-lime-felspar).....	65-62
Andesine (soda-lime-felspar).....	62-56
Labradorite (lime-soda-felspar).....	56-49
Anorthite (lime-felspar).....	48.3

Orthoclase (Gr. *orthos*, 'straight,' *klasis*, 'a fracture') is so called because the two cleavage-planes of the mineral are at right angles to each other. As a rock-former, it occurs most frequently in the form of imperfect crystals or irregular crystalline aggregates. In porphyritic rocks, and especially in drusy cavities in such rocks as granite, it often appears in tolerably well-developed crystals.

It is an essential constituent of granite, syenite, orthoclase-porphry, and quartz-porphry. The compact ground-mass of the two last-mentioned rocks is largely composed of micro-crypto-crystalline orthoclase. Orthoclase occurs also as an accessory ingredient in most plagioclase rocks, and is present in many of the crystalline schists, especially the gneissose rocks. A clear glassy variety of orthoclase called *sanidine* is a common constituent of many igneous rocks of Tertiary and Recent date, such as liparite, phonolite, trachyte, &c. Orthoclase, as a rule, is readily acted upon by the weather—the potash and some of the silica being removed in solution, while a fine-grained clay or Kaolin is left behind. Ordinary orthoclase is either gray, white, or flesh-coloured, and these tints of the felspar generally determine the colour of the rock in which it occurs. Thus we have *gray* granites and *red* or *pink* granites.

Microcline has the same composition as orthoclase, and its cleavage-angles differ so very slightly from a right angle that it might well be looked upon as simply another form of orthoclase. It is frequently associated with the latter in plutonic and schistose rocks.

The other triclinic felspars are grouped together as *Plagioclase* (Gr. *plagios*, 'oblique,' and *klasis*, 'a fracture,' in reference to the cleavage-planes, which are not at right angles to each other), and are among the most important rock-formers. According to Tschemak, they form a series of which anorthite and albite are the extremes, while the others are isomorphous mixtures of these two types in various proportions. The plagioclase felspars often assume a tabular aspect when growth has been confined almost entirely to two parallel faces. At other times the crystals, owing to extension in the direction of the principal axis, acquire a long prismatic form. As rock-formers they occur either as well-developed crystals, or as narrow lath-shaped microlites, or sometimes as a crypto-crystalline matrix or ground-mass, through which other rock-forming minerals are disseminated. On fresh unweathered faces of an igneous rock the crystals frequently appear as clear glassy strips or rods, in which may often be detected by the eye or by a lens a fine parallel striation, formed by the union of many twins, sometimes thirty or more appearing in one and the same crystal. This structure is never seen in orthoclase. This repeated twin-lamination has been developed artificially in untwinned plagioclase by subjecting the mineral to a high temperature, and the same molecular change has been superinduced by pressure. Plagioclase is an essential constituent of many igneous rocks, and it is likewise met with in many crystalline schists, in which it is the product of hypogene metamorphic action. *Albite* is a common constituent of some crystalline schistose rocks. It is found in igneous rocks in perthitic intergrowths, and as a 'juvenile' mineral after basic plagioclase. *Oligoclase* occurs both in the older and younger eruptive rocks, and also in many crystalline schistose rocks. *Andesine* is met with rarely in crystalline schists, but is a common constituent of some eruptive rocks, such as andesite. *Labradorite* is an essential constituent of such rocks as gabbro, basalt, &c. It occurs also in metamorphic rocks, sometimes in large crystalline masses. It often shows fine chatoyant reflections, receives a fine polish, and is occasionally employed in jewelry. *Anorthite* is not common as a rock-former. It occurs in some igneous rocks of low silica percentage, and also in certain metamorphosed limestones.

The felspars which occur in rocks that contain much free silica (quartz) are generally orthoclase and microcline, but with these are frequently asso-

ciated the sodium-rich plagioclases, albite and oligoclase. The chief habitats of the basic plagioclase feldspars are basic igneous rocks.

Common feldspar or orthoclase, under the name of *Petunse* or *Petunze*, is employed by the Chinese (along with some of the quartz associated with it) in the manufacture of porcelain. It is used with other materials as a flux, and alone to form an enamel or glassy covering, without which the porcelain would absorb moisture and grease. *Kaolin* (Chinese) is the name given to the fine clay which results from the decomposition of feldspar by weathering or, as in Cornish granites, by pneumatolysis. *Adularia* is a transparent variety of orthoclase, often showing pearly opalescent reflection, and sometimes a play of colours. The finest specimens of this variety are cut as ornamental stones, and known as *moonstones*; they show a shimmering play of white light often tinged with blue. Another kind, found among rolled stones in Ceylon, and remarkable for the reflection of a pearly light, has occasionally been confounded with Cat's-eye (q.v.). *Sunstone*, or *aventurine feldspar*, is somewhat similar to the variety of quartz called *Aventurine* in the play of light which it exhibits—a property which seems to be due to disseminated crystals or plates of hematite or goëthite. The aventurine effect is found in a number of feldspars, but is most common in oligoclase. *Amazon-stone* is a bright verdigris-green microcline, fine specimens of which come from Pike's Peak, Colorado. *Peristerite* is a whitish adularia-like albite.

Felstone, a rock-term now disused. It comprised a number of rocks composed chiefly of feldspar, sometimes orthoclase, and sometimes plagioclase. These rocks are now referred to quartz-porphry and porphyrite.

Felt, a fabric formed without weaving, by taking advantage of the natural tendency of the fibres of wool and certain kinds of hair to interlace with and cling to each other. When one of these fibres is examined by the microscope, it is found to be minutely notched or jagged, the barbs pointing to the tip of the hair. Some fibres of this kind, however, such as human hair and horse-hair, are too nearly smooth or too rigid for felting purposes. Among the most suitable fibres are those of the sheep, goat, ox, hare, rabbit, musquash, and beaver. Some of these are used chiefly for felt hats (see **HAT**). Felted cloth is made principally from wool, but less valuable substances are mixed with it.

The making of felted fabrics is a very ancient art in some parts of Asia, and to this day the thick *nimnuds* or *nammuds* of Persia and Turkestan are remarkable not only for their durability, but for their beautiful ornamentation, produced by a felted inlay of coloured wools.

The first successful mechanical process for the manufacture of felt was invented by Mr J. R. Williams, an American, in the decade 1820-30, Mr Wells, also an American, being associated with him. Williams took out a patent for the process, or for a modification of it, in England in 1840, and about this time a large factory was erected by some capitalists at Leeds to manufacture felt cloth under the patent. The company speedily attained great prosperity, but in the full tide of its success the mill was destroyed by fire. Williams, whose whole property was in the concern, which was not insured, soon afterwards died of grief.

Felton, CORNELIUS CONWAY, president of Harvard College, was born in West Newbury, Massachusetts, in 1807, and studied at Harvard, where, after filling several minor posts, he became in 1834 Eliot professor of Greek, and in 1860 president.

He died 26th February 1862. He published translations of modern European works, and editions of Greek classics; his chief work, however, was his posthumous *Greece, Ancient and Modern* (2 vols. Boston, 1867), mostly made up of lectures delivered before the Lowell Institute.

Felton, JOHN (c 1595-1628), the assassin of the Duke of Buckingham (q.v.).

Feltre (ancient *Feltria*), a town of Northern Italy, 19 miles SW. of Belluno; pop. 7000.

Feltre, VITTORINO DA, is the name by which a great Italian educationist (1378-1446) is known, though Ramboldi was his family name. Born at Feltre, he lectured at Padua and Venice; and as tutor to the children of the Marchese Gion Francesco Gonzaga of Mantua, conducted a school in which they and other noble boys studied on a footing of strict equality with poor youths. He was a forerunner of Pestalozzi, and his school became a model for imitation. Rosmini wrote a Life of him (1881), and, in English, Woodward (1897).

Femern, a flat and fertile island of Sleswick-Holstein; area, 70 sq. m.; pop. 10,000.

Femgerichte. See **VEHMGERICHTE**.

Feminism. See **WOMEN'S RIGHTS**.

Femoral Artery. See **ARTERIES**.

Fences, in Agriculture, serve in general the threefold purpose of inclosing animals on pasture-grounds, of protecting land from straying animals, and of affording shelter from cold winds. In countries where wood or stones are scarce, and more especially where the land has been long settled, hedges formed of various kinds of plants are common. These, when grown upon good soil, and when well kept and managed, give a clothed and picturesque appearance to the landscape. The hawthorn or white-thorn is the favourite hedge-plant in Britain. See **HEDGES**.

Stone walls, when well constructed, form the best fences. The form and mode of building varies with the nature and quality of the stones. In Aberdeenshire the walls or dykes surrounding the fields are constructed of granite boulders that are found strewn over the surface of the country. The Silurian of the southern counties of Scotland supplies durable but irregularly shaped whinstone, which forms a lasting but rough fence.

In new countries, where wood is abundant, the fences are all of this material. The snake-fence, named from its zigzag form, is made by merely laying trees above each other, in such a manner that their ends overlap and cross, and require no additional fixing. As wood becomes more valuable, it is made into posts and rails. The posts are driven into the ground from two to three yards apart, and from four to five rails are nailed across, according to the purpose which the fence is meant to serve. The stob and rafter fence is made by driving the posts in the ground at a distance of from three to four inches apart, and binding the whole by a rafter or rail nailed across the top. This is one of the strongest of wooden fences, but requires more material than the other. In America split rails, roughly sharpened at either end, and let into wide openings cut into the posts, are in common use.

Iron or wire fencing is the form most frequently adopted at the present time. Vast stretches of waste land in Britain, as well as pastures in Australia, have been inclosed by means of wire-fencing. Strong wires are stretched on staking-posts firmly secured in the ground 200 yards apart. Intermediate or lighter posts—standards for support, or hangers in the hollows to keep down the wires, as the case may be—are put in at from two to three

yards' distance. After the wires are fully stretched they are fixed to the smaller posts; when of wood, by means of staples, or threaded through, when of iron. Barbed wire is now extensively used in fencing cattle, both in Britain and elsewhere. The only danger of serious injury from the use of barbed wire is when an animal runs close to and in the line of the fence; a horse can thus saw the skin and flesh through, and lay the shoulder-joint open in a few seconds. Various forms of fencing can now be obtained ready made, in which the several wires, at convenient distances apart, are fixed together by strong cross-wires welded to them, or by thin wooden or iron uprights. The fence is held by strong posts driven into the ground at intervals of five or six yards. This type is easily erected, and may be easily taken down and re-erected elsewhere.

In Scotland the landlord is held bound to put the fences on the farm in due repair on the entry of the tenant, independently of any stipulation in the lease; whilst both in England and Scotland the tenant must maintain the fences and leave them, with the exception of ordinary tear and wear, in the state in which they were given over to him. A tenant who erects a temporary fence (e.g. a wire-fence), can, unless he makes a special agreement to the contrary, remove the same as a temporary fitting, provided the ground on which it stood is left in the original natural condition.

Fencing may be generally described as the scientific handling of a sword or bayonet in attack or defence, though the term is usually limited to the use of the rapier. It is taught in every gymnasium, and in the British army every officer on joining is put through a course of gymnastics of which it forms a part. Non-commissioned officers are taught at the Aldershot Gymnasium, and then appointed instructors throughout the army.

FENCING WITH THE RAPIER OR FOIL is admitted to be the best exercise that can be taken. Every muscle of the body is brought into play by it, and hand and eye are trained to act in unison. No description can pretend to teach it. Even an instructor who is not thoroughly capable does more harm than good in attempting to teach fencing, as bad habits are acquired which it is most difficult to unlearn; and, unless every movement is accurately and properly made, there is no science and very little interest in its practice.

The foil in practice used as a substitute for the rapier should have a tapering blade about 32 inches long, and square in section, with a gutta-percha button on the point, and a weighted pommel to the hilt, so as to balance it properly. Masks of wire netting are absolutely essential to protect the face, and leather gloves, jackets, and aprons should also be worn.

Except in Spain, where one straight cut at the head is allowed, the only attack with the rapier or foil is by *thrust* and *lunge* (or *lunge*)—i.e. straightening the elbow so as to bring the sword and arm into line, and then striding forward about 18 inches with the right foot. The defence is by slight movements of the sword hand, which cause the *faible* (upper half) of the assailant's blade to glide along the *forte* (lower half) of the defender's foil, and outside it, so as to pass clear of his body, while his point is always kept towards the front, ready to *ripost* (longe after parrying) without an instant's delay. The proper positions and movements when *on guard*, *engaged*, *longeing*, *parrying*, *advancing*, and *retreating* must be most carefully learned from an instructor, and assiduously practised, as well as the various attacks. A reproduction (fig. 1) of the diagram given by Captain Chapman in his excellent little book, *Foil*

Practice, shows the four lines of attack and the nine parries usually taught. It will be sufficient to mention that a *counter parry* describes a circle

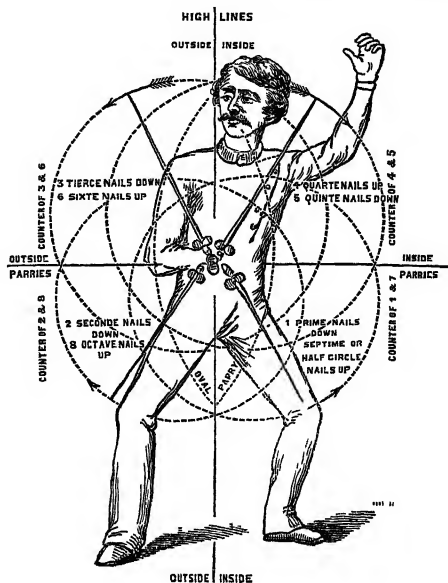

Fig. 1.

under or over the adversary's foil before throwing it off, and to add the following explanation of terms used in fencing. When the nails are uppermost the sword hand is said to be in *supination*, when under, in *pronation*. The thrusts, like the parries are called *quarte* (or *carte*), *tierce*, &c. The *flanconade* is an attack made by the assailant *binding* his blade round the adversary's and *longeing* at his body under his arm. An attack may be a combination of any of the following movements preceding a *longe*: *disengage*, when swords are crossed, changing from one line of attack to another by passing under the adversary's sword; *cut over*, the same change by whipping over his sword; *one, two*, a double disengagement; *double*, both blades horizontal, and circling round parallel to one another; and *beat*, a side-blow of one blade on the other. If a second thrust is made after *longeing*, and without springing up to guard again, it is called a *reprise*; and, if made to take advantage of a wide parry not followed by a *ripost*, a *remise*. *Time thrusts*, like cross-counters in boxing, parry a thrust by a thrust.

The system of fencing compiled by Mr Archibald Maclaren, of the Oxford Gymnasium, is that used in the British army, and differs from others in teaching only four parries—viz. *quarte*, *tierce*, *seconde*, and *semicircle*. All are formed in the usual manner, except the last, which, by raising the hand slightly and elevating the blade as high as the face, guards both the upper and lower openings on the inner or left side, carrying the adversary's blade over the right shoulder, and leaving him completely exposed to the return thrust. In Spain and Italy the left hand is used as an auxiliary in parrying, and in Italy is aided by a dagger, or a cloak.

THE BROAD-SWORD EXERCISE differs from fencing with the foil, in that the weapon employed is intended to cut as well as thrust. For practice a stout, straight stick is used ('single-stick'), with buffalo-hide or basket handle to protect the knuckles.

The position and movements of the combatant are very similar to those for fencing with the foil, but the position *on guard*, the start of a formal

fight, has nails down, while in fencing the corresponding position has nails up. There are seven cuts, with seven corresponding guards, and three thrusts, as shown on the accompanying diagram, which represents a target placed opposite a pupil, with its centre in a line with the centre of his breast.

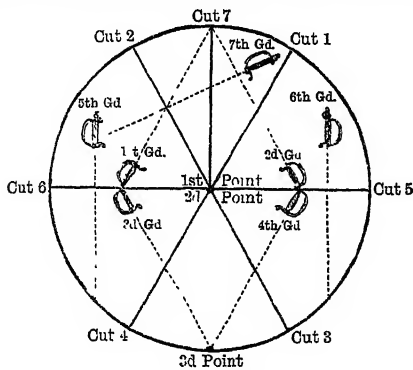

Fig. 2.

The cuts cross the whole circle through the centre along the *thick* lines. Nos. 1, 3, and 5 are inside cuts, and may be directed against any part of the left side, and inside of the right leg; 2, 4, and 6 are outside cuts, attacking the right side, and right leg on the outside. No. 7 is a vertical cut, aimed at the head. The dotted lines show the several guards. The points or thrusts are shown by the black dots. The 'parry' consists in bringing the wrist nearly to the right shoulder; whence, as centre, a circular sweep of the sword is made from left to right.

CAVALRY SWORD EXERCISE differs from the foregoing, which is not suitable for horsemen. It has four cuts on each side, two at a mounted, and two at a dismounted adversary. Each cut has a corresponding point and guard.

THE BAYONET EXERCISE taught in the British army has been assimilated to Maclaren's system of fencing. The guards are formed in as nearly as possible the same manner, except that, of course, the rifle is held in both hands, one at the grip, and one in front of the back-sight. The latter remains almost stationary, while the movements of the other form the parries. A most effective thrust, called the *throw*, has been introduced. When making it, the forward hand quits the rifle, which is thrown forward to the full extent of the other arm.

As to the relative values of the sword, rapier, and bayonet, the first, requiring for each cut two motions, one up and the other down, cannot but be much slower in its action than either of the other two; while the last, from its weight, is exhausting and clumsy. The second, on the other hand, has none of these objections, and in skilled hands is by far the most deadly weapon.

See Captain Chapman's *Foil Practice*; Maclaren's *System of Fencing* (1864); Captain A. Hutton's *Cold Steel* (1889); the *Manuals of Sword and Bayonet Exercise* published by the War Office; and *Fencing, Boxing, and Wrestling* in the 'Badminton' series, by Grove, Pollock, Armstrong, and Prévost (1889).

Fen Country. See BEDFORD LEVEL.

Fénelon, FRANÇOIS DE SALIGNAC DE LA MOTHE, was born August 6, 1651, in the château de Fénelon, province of Périgord, now included in the department of the Dordogne, of a family which has given many celebrities both to the church and to the state in France. His education was conducted at home up to his twelfth year, when he

was transferred to Cahors, and afterwards to the Plessis College in Paris. In his twentieth year he entered the newly-founded seminary of St Sulpice, where he received holy orders in 1675. Unlike too many ecclesiastics of his own rank at that period, he gave his whole heart to his sacred calling, being for some time employed in the parochial duties of the parish of St Sulpice; and in the year 1678 he was named director of an institution recently founded in Paris for the reception of female converts to the Roman Catholic faith. During his tenure of this office he wrote his first work, *De l'Éducation des Filles*; and the success with which he discharged his duties towards the young converts led to his appointment as head of a mission, which, on the revocation of the Edict of Nantes in 1685, was sent to preach among the Protestant population of Saintonge and Poitou. In 1689 he was named by Louis XIV. to the highly confidential post of preceptor of his grandson, the young Duke of Burgundy. In the discharge of this delicate trust he sought to impress on his pupil's mind the great principles of truth and justice upon which the prince's responsibilities are founded, and to show the hollowness and futility of all earthly glory, power, and happiness which do not rest upon this foundation. To this wise design of the preceptor we are indebted for many works still popular in educational use; for the *Fables*, for the *Dialogues of the Dead*, for the *History of the Ancient Philosophers*, and for the germ at least of the *Télémaque*. As an acknowledgment of these great merits, he was presented by the king in 1694 to the abbey of St Valery, and in the following year to the archbishopric of Cambrai.

It is to this period of Fénelon's life that the history of the unhappy controversy about Quietism (q.v.) belongs. Two separate schools of Quietism are to be distinguished. In one of these the common mystic principle of the absorption of the soul in the love and contemplation of God led to the conclusion that the soul, in this state of absorption, suffered no contamination from the material actions of the outer man, and that no acts of virtue, not even of prayer, were any longer required (see MOLINOS). The other school, while it maintained the theory of passive contemplation and love, yet repudiated the dangerous and immoral consequences which were deduced therefrom. It was exclusively the latter and less objectionable form of Quietism the professors of which for a time claimed, although not the patronage, yet at least the indulgent consideration of Fénelon. He formed in the year 1687 the acquaintance of the celebrated Madame Guyon (q.v.). Fully convinced of the unfairness of much of the outcry which was raised against her, and which made her responsible for all the principles of the grosser Quietism of Molinos, his generous mind was perhaps attracted to her cause by the very injustice of her opponents. He advised her to submit her works to the judgment of Bossuet, who was then in the zenith of his fame, and with whom Fénelon was in the most friendly relations. In the condemnation of the book of Madame Guyon by this prelate Fénelon acquiesced; but, as she made a formal submission to the church, he refused to join in any condemnation of herself personally. Nevertheless, when a commission was appointed to examine the whole affair, he signed their report. It was not thought enough to publish a condemnation of her several works, but Bossuet prepared a special exposition of the true doctrine of the church on these questions. To this work Fénelon refused to give his approval, and even composed his own *Explication des Maximes des Saints sur la Vie intérieure* in explanation and defence of certain at least of Madame

Guyon's doctrines; he cheerfully agreeing to the stipulation of the Archbishop of Paris that the *Mémoires* should be kept back from publication until the completion of the rival treatise of Bossuet, *Instruction sur les États d'Orléans*. An unfortunate violation of this engagement, committed without the knowledge, and in the absence of Fénelon, was the last of a long train of causes which led to the painful and unedifying rupture between these two great prelates. Fénelon's book was received with much clamour, that of Bossuet was universally approved; and in the controversy that ensued all the displeasure of the court, which Fénelon had provoked by covert strictures in his works of fiction, was brought to bear against him. He was ordered to submit his book to the judgment of an ecclesiastical tribunal, of which Bossuet was a member. He refused to accept Bossuet as judge; and in the end he appealed to the judgment of the holy see. Bossuet published a succession of pamphlets; several of the bishops who had espoused the side of Bossuet issued pastorals in the same sense; and Fénelon defended himself vigorously against them all.

The last blow against the ancient friendship of the great rivals was struck by Bossuet in his celebrated *Relation sur le Quétisme*. Fénelon was wounded to the heart; but his most masterly defence was written, printed, and published within little more than a fortnight from the appearance of Bossuet's *Relation*. From this point the controversy assumed a more personal and therefore a more acrimonious character; and it was maintained on both sides till the long-delayed decision of the pope brought it to a close, March 12, 1699, by a brief, in the usual form, condemning the *Maximes des Saints*, and marking with especial censure twenty-three propositions extracted from it. The conduct of Fénelon under this blow constitutes, in the eyes of his fellow-churchmen, one of his highest titles to glory. He not only accepted, without hesitation, the decision of Rome, but he took the very earliest occasion to publish from his own pulpit the brief of his condemnation. The jealousy with which the political principles of Fénelon were already regarded was heightened about this time into open hostility by the appearance of his *Télémaque* (see *TELEMACHUS*), printed from a copy surreptitiously obtained by his servant, which the king regarded as but a masked satire upon his own court. Louis's anger knew no bounds. Fénelon was strictly restrained within his diocese; and measures were taken to give the condemnation of his book every character of publicity. From this date Fénelon lived exclusively for his flock. He founded at Cambrai a seminary for his archdiocese, which he made his own especial charge. He was assiduous in preaching and in the discharge of the other duties of his office; and the fame of his benevolence, charity, and enlightened liberality is attested by the order issued by the Allies in the campaign of 1709 to spare the palace and the stores of the Archbishop of Cambrai. The only later controversy in which he appears is the revival of the Jansenistic dispute, in which Fénelon engaged earnestly on the side of orthodoxy. He died January 7, 1715, and was buried in his cathedral of Cambrai (q.v.).

The works of Fénelon are very voluminous, and embrace every variety of subjects—theology, philosophy, history, literature ancient and modern, and oratory, especially the eloquence of the pulpit. His correspondence is very extensive and most interesting. Of his mature discourses two only have reached us in a finished state. They are of the very highest order of sacred eloquence. His work on the temporal power of the medieval popes presents that doctrine in its most amiable form;

and even his spiritual writings are not unfrequently read by Christians of all denominations.

See Bausset's edition of the Works (22 vols. 1821-24), also the Abbé Gosselin's (10 vols. 1848-52), to which is prefixed Bausset's *Histoire de Fénelon* (1808; new ed. 1862); Mme. Duclaux, *The French Ideal* (1911); Paul Janet's *Fénelon* (1892; trans. 1913); uncritical Lives by Mrs Lear (1876) and E. K. Sanders (1901); and the Life by Viscount St Cyres (1901). Douen, in *L'Intolérance de Fénelon* (1872), endeavoured to establish by documents that both in his management of the institute for the converts and in his measures in Portou, Fénelon frankly accepted the policy of persecution, and was guilty of inexcusable severity and even cruelty.

Fenestella, or FENESTRELLA, a genus of Polyzoa, resembling the recent 'lace coral,' very common in Palæozoic rocks, from the Lower Silurian to the Permian.

Fenians, or FENIAN SOCIETY, was a popular name for the Irish Republican Brotherhood, a political association of Irish or Irish-Americans for the overthrow of the British authority in Ireland, and the establishment of a republic. The words *Fiann*, *Fianna* are used of the ancient Irish militia of the kings Conn of the Hundred Battles, his son Art, his son Cormac MacArt (who began to reign at Tara in 213 or in 227 A.D.), and Cormac's son Cairbre, who in the battle of Gabhra destroyed the power of the militia, now mutinous and inclined to side with Connaught against the high-kings of Ireland. Dr Douglas Hyde, in his *Literary History of Ireland* (1899), calls the tales illustrating the enmity that arose between the high-kings and their militia the 'Fenian Cycle' of romances; it might also be called the Ossianic cycle, since Ossian is said to have written many of these tales. The word *Fenian* has, however, nothing to do with the name of Finn MacCúmhail, though by 'Finnian' Moore no doubt meant 'followers of Finn MacCool.' In the earlier English translations of Keating's Irish history the word is not used, but 'Irish militia.' Miss Brooke, translating some Ossianic fragments, is the first to use the English form Fenian (1796). John O'Mahony, brilliant Irish scholar and head-centre of the I.R.B., christened the 'men of '68' Fenians. The I.R.B.—of which the Clan-na-Gael was the American branch—was in Ireland the mainspring of Home Rule, the Land League, and Nationalism.

The modern Fenian movement adopting the name of this ancient military association had its first seat in America, where the Irish population had largely increased since the famine of 1846-47. Many of the emigrants being driven from their homes by arbitrary ejection, or from inability to pay rent, carried with them a sense of wrong; others had been sympathisers if not participants in the insurrection of 1848; and almost all were deeply imbued with general political and social discontent. The most openly active seat of the organisation was in the western states, especially Chicago; but the movement was directed from New York, and possessed ramifications in almost every city of the Union. It was conducted by a senate, and consisted of 'circles,' each directed by a centre. The duty of the centres was to enrol members, who bound themselves, generally by oath, 'to be faithful to the Irish Republic as at present virtually established;' to instruct and practise them in military exercises; to raise funds for the purposes of the association, especially for the purchase of arms and munitions of war; and to extend the organisation by every means at their disposal. Agents were sent into Ireland, and to the chief seats of the Irish population in England; and, opportunely, the termination of the civil war in America set free a large number of men with

military training and experience. In this, unlike almost all similar movements, pains had been taken to exclude the Catholic clergy, by whom the Fenian confederation had from the first been steadily resisted, from all knowledge of its character and objects, as well as of the names or number of its members in the several localities.

By degrees the movement acquired solidity, and the British government ascertained that Fenianism, however corrupt in some of its sources, and however wild and extravagant in its aims, was nevertheless a reality with which it had become necessary to grapple. The Habeas Corpus Act having been summarily suspended, all the known leaders in Dublin and in the provincial districts of Ireland (most of them Irish-Americans) were at once placed under arrest. The 'Head Centre,' James Stephens, was one of those arrested. The chief journal of the conspiracy, *The Irish People*, edited by O'Donovan Rossa, was suppressed and seized; additional troops were moved into Ireland, and other measures of repression were vigorously carried out. Many of the prisoners, convicted of treason, were sentenced to penal servitude. By these energetic measures public tranquillity was maintained in Ireland, but the embers of discontent continued to smoulder among the poorer peasantry and the working population of the towns; and a certain prestige was given to the fallen cause by Stephens' escape from prison. His return and that of other exiles to America renewed the agitation in that country. In the early summer of 1866 a raid was attempted into Canada, which proved an utter failure; and it was followed in the spring of 1867 by an utterly abortive attempt at insurrection at home, beginning with the seizure of the castle and military stores at Chester. The attempt was defeated by the treachery of one of the conspirators. A partial insurrection, however, took place in the county of Kerry; and a few weeks later a more extensive movement was attempted in the counties of Dublin, Louth, Tipperary, Limerick, and Cork. But most of the parties dispersed or were made prisoners after a single night's campaign. The rest betook themselves to the mountains, and after a few days of exposure and hardship were either captured or dispersed. The leaders were tried at a special commission held in the spring of the year 1867, some being convicted, but none executed; and tranquillity for a time seemed to be restored in Ireland. In September 1867 an attack was made, in open day, on a police-van in Manchester; the officer in charge was killed, and the prisoners, who were suspected Fenians, were released. A few weeks later a still more daring attempt was made to blow down Clerkenwell Prison wall, with the same object.

In 1871 the United States government frustrated another Fenian raid on Canada by the apprehension of its leaders and the seizure of its arms. Later developments of the Fenian spirit appeared (1883-85) in the *Skirmishing Fund*, raised to promote the free use of dynamite for the destruction of English public buildings and English commerce, and in the extreme party of the *Glan-ni-Gael*; and some of the 'invincibles' who were to 'make history' by removing tyrants, as in the Phoenix Park assassination (1882), had been Fenians. Some also of those who were leaders in the Home Rule and Land League agitations had formerly been members of the Irish Republican Brotherhood.

See the history of IRELAND in this work; J. Rutherford's *Fenian Conspiracy* (1877); J. O'Leary's *Recollections of Fenians and Fenianism* (1896).

Fennec (*Canis cerdo*, *famelicus*, *chama*), little African foxes, of elegant habit and active, courageous disposition. The ears are remarkably large. Fennecs are found apparently throughout Africa,

and are sometimes hunted. In diet they show an interesting though not unique fondness for sweet vegetable food, such as dates. (Quite distinct is the decidedly larger African Fox (*Otocyon megalotis*). See FOX.

Fennel (*Feniculum*), a genus of umbelliferous plants, allied to Dill (q.v.), but distinguished by the cylindrical, strongly-ribbed fruit. The flowers are yellow. All the species are aromatic, and have much-divided leaves with thread-like segments. The best known is the Common Fennel (*F. vulgare*), a native of the south of Europe and of some parts of England. It is a biennial, 3 or 4 feet high, and is cultivated in gardens, chiefly for the sake of its leaves, which are boiled, and served up with mackerel, with salmon, and occasionally with other kinds of fish, or are employed to form a sauce for them.—Sweet Fennel, Italian Fennel, or Cretan Fennel (*F. dulce*), is a plant of much humbler growth, an annual, much cultivated in the south of Europe, but too tender for the climate of Britain. The greatly dilated bases of the petioles are less aromatic than those of Common Fennel, and when blanched form a very agreeable salad and potherb. The fruit (seed) is longer and paler than that of Common Fennel, has a more agreeable odour and flavour, is a favourite aromatic condiment of the Italians, and is used in medicine as a carminative and aromatic stimulant. *Oil of Fennel*, an aromatic, stimulant, and carminative essential oil, is also made from it.—Cape Fennel (*F. capense*), found in the interior of the Cape of Good Hope, has a thick, aromatic, esculent root.—The Panmuhooree of India (*F. panmorum*) is a species cultivated for its sweet, warm, and aromatic fruit, which is much used as a carminative, and in curries.—The Giant Fennel of the south of Europe is a plant of a different genus (*Ferula*), and abounds in a fetid juice; it is indeed closely allied to *Asafoetida*. It forms a favourite food of buffaloes in Apulia, where it particularly abounds. The dry, dead stem is full of a white pith, which is used in Sicily as tinder.

Fennel (*Feniculum vulgare*):
a flower.

Fens. See BEDFORD LEVEL.

Fenugreek (*Trigonella*), a genus of Leguminosae, allied to clover and melilot. The Common Fenugreek (*T. fenum Græcum*) is a native of the south of Europe, and of some parts of Asia; it is much cultivated in India as a fodder-plant, and derives its name since classic times (*Fenum Græcum*, 'Greek hay,' of which the English name is a corruption) from its use as fodder in Greece. On account of its strong smell it must, however, be mixed with other plants. The seeds also have a strong, peculiar smell, and an oily, bitter taste; the flour made from them is used for emollient poultices, but only in veterinary practice. The

seeds of Fenugreek were formerly held in great esteem in medicine, and are still largely consumed by women in the East, especially in Egypt. An Indian species (*T. incisum*) is used as fodder, and the legumes of another (*T. esculenta*) are esteemed as food.

Fenwick, SIR JOHN, was born about 1645, and, after serving in the army, in 1688 entered parliament as Tory member for Northumberland. He afterwards entered ardently into the conspiracy known as the Assassination Plot (see ASSASSINATION), and in 1696, being committed to the Tower, made an artful confession involving several Whig leaders in the Jacobite intrigues. Since the only witness against him had been spirited out of the country, the Whig party, furious at these charges, secured the passing of a bill of attainder against Fenwick, under which he was beheaded, 28th January 1697.

Feodosia, or THEODOSIA. See KAFFA.

Feoffment (*infeudure*), the oldest and for a long period the only method for the conveyance of land known in England. Feoffment consisted in the formal conveyance of the land from the feoffor to the feoffee, the former stating distinctly the measure of the estate conferred, whether it was in Fee (q.v.), in tail, or for life. Where no mention of the duration of the estate was made, the gift was presumed to be for life. This conveyance of the land, in order to be complete, required to be accompanied by Livery of Seisin, which was of two kinds—viz. in deed and in law. In the former case, the parties being actually upon the land, the feoffor, by delivery of a twig or a turf, testified his conveyance of the land. In livery in law, the parties being in sight of the land, the feoffor referring to the land gave possession to the feoffee 'in name of seisin.' This mode of feoffment was ineffectual unless the feoffee entered into possession during the life of the feoffor. Livery in deed might be effected by attorney; but livery in law only by the parties themselves. When the practice of embodying the transaction in a deed was introduced it became customary, but not essential, to indorse on the deed the fact that livery of seisin had been made. By the statute of Frauds, passed in 1678, it was declared that no estate created by livery of seisin, unless accompanied by writing, signed by the party or his agent, should be of any effect, except as an estate at will. A feoffment is now void unless accompanied by deed. The law formerly gave so great an effect to a feoffment that a party could in some cases convey a greater estate than he had; the parties wronged by his act being disseised of their estates unless they could recover them by entry on the land or by action. But a feoffment now has no tortious operation. Feoffment was the form adopted for conveying the legal estate in land to trustees or 'feoffees to uses' (see USES). It must be observed that the practice of feoffment above described, which has existed in England from time immemorial, differed materially from the old form of investiture in use in strictly feudal times, and from that which still prevails in Scotland. In England the transaction was simply a conveyance by the actual holder of the land to a new tenant, testified by certain ceremonies, but requiring no confirmation by the lord to complete it. In Scotland no transfer of heritage is complete without the formal confirmation of the superior; acceptance by the superior, and the performance of the pecuniary services attendant on that acceptance, are still preserved. See the articles INFERTMENT and FEUDAL SYSTEM.

Feræ Naturæ (Lat., 'of a wild nature') is the term given by Roman law to those animals which

are wild or not domesticated, including game animals—deer, hares, pheasants, &c. See GAME LAWS.

Ferdausi. See FİRDAUSI.

Ferdinand THE CATHOLIC, V. of Castile, II. of Aragon and Sicily, and III. of Naples, was born at Sos in Aragon, 10th March 1452, the son of John II. of Navarre and Aragon. By his father he was formally associated in the government of Aragon in 1466, and appointed king of Sicily in 1468; in 1469 he married, at Valladolid, Isabella, sister of Henry IV. of Castile. On Henry's death in 1474 most of the nobles refused to acknowledge the legitimacy of his daughter Juana ('La Beltraneja'), and proclaimed Isabella and her husband Ferdinand joint-sovereigns, who, in 1479, emerged victorious from the civil war that ensued. In that year also Ferdinand became king of Aragon on the death of his father, and the two kingdoms of Aragon and Castile were united in the persons of Ferdinand and Isabella; the latter, however, as long as she lived, maintained control and authority in Castilian affairs. The reign that followed is one of the greatest in the history of Spain, which was in a few years advanced to the first rank among the nations by the military, administrative, and diplomatic skill of its sovereigns, and of the distinguished body of ministers and generals that surrounded them.

Ferdinand's political talents found plenty of scope in the distracted condition of affairs which met him on his accession—the kingdom split into factions, feuds raging between the great houses, and robbery and outrage rife in every quarter of the country. The effectual suppression of the banditti he accomplished by reorganising the *santa hermandad*, or 'holy brotherhood,' a kind of militia-police, composed of the citizens and the country-people. Moreover, a principal aim of Ferdinand and Isabella was to break the power of the feudal aristocracy, and good use was made of the *hermandad* in carrying out this design. The establishment of the Inquisition in 1478–80, although primarily and mainly intended to further 'religious' ends, likewise helped to lessen the nobles' influence; and Ferdinand also strengthened his power by vesting in himself and his successors the grand-mastership of the military orders of Calatrava, Alcántara, and Santiago. In all his schemes he was ably seconded by his queen and by the celebrated Cardinal Ximenes.

The year 1492 was the most brilliant in his reign. It opened with the fall of Granada, which marked the end of the long struggle with the Moors; and in August Columbus set sail from Palos. Although the free exercise of their religion was guaranteed to the Moors, an edict for the expulsion of the Jews from the conquered kingdom was immediately signed; and, a few years after, the privileges secured to the Moors were treacherously withdrawn, baptism or exile being offered as alternatives. By these two barbarous and unwise acts the most industrious and civilised inhabitants of the Peninsula were driven from it. The discovery of America, however, for a time gave Spain almost unchallenged supremacy along both shores of the Atlantic, and Ferdinand turned his attention to European affairs. From France he recovered by treaty the counties of Roussillon and Cerdagne (now the Pyrénées Orientales), which his father had mortgaged to Louis XI.; in 1495 he formed the Holy League, with the pope, the emperor, and the states of Milan and Venice (Henry VII. of England was persuaded to enter the league nearly sixteen months later), under which Gonsalvo de Cordova drove the French out of Naples; and in 1500–1 the French king was induced to join him in

the conquest and partition of Naples, only to be overreached by the Catholic king, and compelled to yield up the kingdom to him entirely three years later.

In 1504 Isabella died, and Ferdinand at once had his insane daughter Juana proclaimed queen of Castile, and himself regent; but Juana's husband, the Archduke Philip of Austria, threatening an appeal to arms, the king threw up the regency, and in 1505 married Germaine de Foix, a niece of Louis XII. of France. Philip died in September 1506, only three months after his landing in Castile; whereupon Ferdinand resumed the administration, which he retained till his death, although his position was greatly changed after Isabella's death, and he was compelled to reverse all his former policy—make an alliance with France, and buy off French claims on Naples—besides being frequently in great straits for money, so that he was for some time unable to send the second portion of the dowry required to secure the marriage of his daughter Catharine with Henry, Prince of Wales. Nevertheless, he took part in the famous league of Cambrai formed against Venice in 1508, conquered Oran in Africa in 1509, and in 1512 seized a favourable opportunity to make himself master of the long-coveted kingdom of Navarre—thus becoming monarch of Spain from the Pyrenees to the Rock of Gibraltar. He died at Madrigalejo, 23d January 1516, and was succeeded by his grandson, best known in history as the Emperor Charles V. Ferdinand's ability, both as a general and as a statesman, has been variously estimated; but at least his skill and shrewdness as a negotiator were unsurpassed in an age of cunning and unscrupulous diplomatists. A characteristic anecdote relates that, on hearing of a complaint made by Louis XII. that he had cheated him once, he promptly answered: 'He lied, the drunkard! I cheated him three times.' Yet to Ferdinand and Isabella Spain owes her unity and greatness as a nation, and under them the foundations were laid of the unrivalled and imperial influence which, in the brilliant reign of their successor, she exercised over Europe. See Prescott's *History of the Reign of Ferdinand and Isabella* (3 vols. Boston, 1838).

Ferdinand I., German emperor from 1556 to 1564, was born at Alcalá in Spain in 1503. He was the son of Philip I., and brother of Charles V., whom he succeeded in the empire in 1556, having been previously elected king of the Romans (1531). Already, in 1521, Ferdinand had married Anna, daughter of Ladislaus, king of Bohemia and Hungary; and when her brother Louis fell in 1526 in battle with the Turks, leaving no issue, he claimed the crown in right of his wife. This involved him in a long and bloody struggle with a rival, John Zápolya, who laid claim to Hungary, and who, as well as his son Sigismund, was supported by Soliman, sultan of the Turks. Ferdinand at last gained the upper hand, bought off the Turks by a yearly tribute, and finally secured Hungary and Bohemia to the House of Austria. When he was elected emperor the concessions he had made to the Protestants caused the pope, Paul IV., to refuse to acknowledge him. That pope dying, his successor, Pius IV., was more complaisant; but the electors resolved that for the future the consent of the pope should not be asked; and this was carried out. Ferdinand made several attempts to reconcile his Protestant and Catholic subjects, and urged, though fruitlessly, the reformation of abuses on the Council of Trent. He died in 1564, leaving the reputation of a prudent and enlightened ruler, and was succeeded by his son Maximilian II. See Bucholtz, *Geschichte der Regierung Ferdinands I.* (9 vols. Vienna, 1831-38).

Ferdinand II., German emperor from 1619 to 1637, was born at Gratz, 9th July 1578. He was grandson of Ferdinand I., his father being Charles, Archduke of Carinthia and Styria, the younger brother of Maximilian. His mother, Maria of Bavaria, early inspired him with hatred against the Protestants, and he was educated by the Jesuits at Ingolstadt, along with Maximilian of Bavaria. It is said that at Loretto he took a solemn oath before the altar of the Mother of God to reinstate Catholicism as the sole religion of his dominions at any cost. As soon as he succeeded to the government of his own duchy of Styria, he set about putting down Protestantism by force. He attempted the same in Bohemia and Hungary, of which countries he had been elected king during the lifetime of his cousin, the childless emperor Matthias; but though at first unsuccessful, and even in danger of losing his dominions, he ultimately managed, with the aid of the Catholic League and of the Elector John George I. of Saxony, to subdue them. Bohemia lost all its privileges, and by merciless hanging, confiscation of property, and the banishment of innumerable families, was reduced to obedience, while by the introduction of the Jesuits, and rigorous persecution of Protestants, he re-established Catholicism. His measures were less entirely successful in Hungary. Meanwhile Ferdinand had been elected emperor of Germany (1619). The war that had already been begun was now transferred to a wider area, and took the character of a religious war—the famous 'Thirty Years' War' (q.v.). The two imperial generals, Tilly and Wallenstein, were opposed by a confederacy of the Protestant states of Lower Saxony, with Christian IV. of Denmark at their head; but the confederates were defeated by Tilly at the battle of Lutter, in Brunswick, and forced to conclude peace at Lubeck in 1629. Confident in the ascendancy which he had acquired, Ferdinand in the same year issued an edict of restitution for the whole of Germany, taking away from the Protestants nearly all the rights they had acquired by a century of struggles; and the troops of Wallenstein and of the League were immediately set to work to carry out this edict in several places. But his further success was soon arrested by the dismissal of Wallenstein, on which the diet of the empire at Ratisbon had insisted, by the opposition of Richelieu, and by the arrival upon the troubled scene of the great Protestant hero, Gustavus Adolphus of Sweden. After the murder of Wallenstein, at which the jealous Ferdinand connived to his eternal disgrace, the imperial commander, Gallas, by the victory of Nordlingen (1634) detached Saxony from the Swedish alliance; but the ability of the Swedish generals, for whom Austria had none that were a match, and the open part that France now took in the contest, brought back the balance of victory so far to the Protestant arms, that ere the wretched Ferdinand died, February 15, 1637, he had lost all hope of ever attaining the object he had pursued with such unreasoning and relentless constancy. His reign is one of the most disastrous in history; for Germany owes him nothing but bloodshed, misery, and desolation. See Hurter, *Geschichte Ferdinands II.* (11 vols. Schaffh. 1850-64).

Ferdinand III., German emperor from 1637 to 1657, was the son of Ferdinand II., and was born at Gratz, 11th July 1608. He was not so much under Jesuitical and Spanish influences as his father. Having accompanied the armies in their campaigns after the death of Wallenstein, he had witnessed the miseries of war, and was inclined for peace; but the conflicting interests of the individual belligerents hindered any unity of view, and made it necessary to proceed with the struggle. Thus was this miserable war protracted, ever

extending in circuit, and increasing in devastation from the growing licentiousness of the soldiery. At last, in 1643, a congress met at Münster to arrange terms of peace, which was concluded in 1648, and is known as the Peace of Westphalia. At the diet of the empire (1653-54), the last presided over by an emperor in person, Ferdinand effected important alterations in the administration of justice. He died 2d April 1637, shortly after concluding an alliance with Poland against Sweden, and was succeeded in the German empire by his son Leopold I.

Ferdinand I., emperor of Austria from 1835 to 1848, was born at Vienna, 19th April 1793, and died at Prague, 29th June 1875. See AUSTRIA.

Ferdinand I., king of the Two Sicilies, was the third son of Charles III. of Spain, and was born 12th January 1751. When his father ascended the Spanish throne in 1759 Ferdinand, though a minor, succeeded him on the Neapolitan throne, under a regency, as Ferdinand IV. After his marriage, in 1768, with Maria Caroline, daughter of the Empress Maria Theresa, he fell completely under her influence, and lost all his former popularity. The queen and her favourite minister Acton (q.v.) ruled the kingdom. Ferdinand joined the coalition of England and Austria against France in 1793, and in 1798 occupied Rome, but soon fled panic-stricken before the French to Sicily on board Nelson's fleet. The French thereupon entered Naples, and set up the short-lived Parthenopean Republic, but were soon obliged to abandon the city and make room for the return of Ferdinand, who contrived to establish his power under the shadow of Nelson's ships. At length, however, in 1801 Ferdinand was forced to enter into a treaty with the First Consul. A subsequent violation of this treaty compelled him in 1806 again to take refuge in Sicily, under the protection of the English. A French army marched into Naples, and took possession of the kingdom, which Napoleon bestowed first on his brother Joseph, and afterwards on Murat. Ferdinand was reinstated by the Congress of Vienna, and entered Naples, after Murat's flight, in June 1815, and in the December of next year united his two states into one, and assumed the title of king of the Two Sicilies. His queen had already died in 1814. He had sworn before his recall to grant a constitution, and a popular movement in 1820 compelled him to renew his pledge, but with the help of an Austrian army the year after he shamefully broke his word and established a rigorous reign of despotism. He died January 4, 1825, and was succeeded by his son Francis I. (died 1830). See Cordy Jeaffreson, *The Queen of Naples and Lord Nelson* (1889); Giglioli, *Naples in 1799* (1903).

Ferdinand II., king of the Two Sicilies, grandson of the preceding, son of Francis I. by his second wife, Isabella Maria of Spain, was born at Palermo, 12th January 1810. He succeeded his father in 1830, and after a brief period of promise soon showed himself as corrupt and worthless a king as his predecessors. His first wife, a daughter of Victor Emmanuel I., dying in 1836, he married Maria Theresa, daughter of the Archduke Charles of Austria, and consequently gave himself more and more up to Austrian counsels, which saw danger for the whole peninsula in liberal measures. Henceforward Naples became the scene of incessant conspiracy, insurrection, bloodshed, and political prosecutions. Ferdinand yielded to the storm of 1848, and granted a constitution to both parts of his dominions, but the Sicilians mistrusted, and with reason, the king's pledges, and declared that he and his family had forfeited the Sicilian crown. Ferdinand followed the constitution so far as to call the promised national parlia-

ment together, but quickly dismissed it, impatient of any interference with his authority. He subdued the revolt in Sicily by the inhuman bombardment of its chief cities that earned him the epithet of 'Bomba,' which will live in history to his eternal dishonour. He now completely set aside the new constitution, while all who had taken any part in state reforms were subjected to those cruel persecutions which the Letters of Mr Gladstone in 1851 held up to the execration of the world. Bomba died 22d May 1859, and was succeeded by his son Francis II. (1836-94), the weak and cowardly 'Bombino,' whose reign of cruelty quickly fell before the victorious enthusiasm of Garibaldi and the triumphant progress of Italian unity. See Nisco, *Ferdinando II.* (Naples 1884).

Ferdinand III., Grand-duke of Tuscany, and Archduke of Austria, was born at Florence, 6th May 1769. On his father's succeeding his own brother on the imperial throne in 1790, he succeeded to the government of Tuscany. Here he inaugurated many judicial, economical, and legislative reforms; encouraged commerce, founded hospitals, and opened up good roads through the state. A lover of peaceful progress, he remained strictly neutral in the first coalition against France, and was the first sovereign in Europe to recognise and treat diplomatically with the French Republic in 1792. Next year the combined menaces of Russia and England constrained him to relinquish his neutral policy and become a passive member of the coalition formed against France, but on the French occupation of Piedmont in 1795 he speedily resumed friendly relations with France. In 1797, in order to save his states from annexation to the Cisalpine Republic, Ferdinand concluded a treaty with Bonaparte on most unfavourable terms, undertaking to pay a war-levy to France, and to transfer to the Museum of Paris some of the chief masterpieces of the Florentine galleries, among them the 'Venus de' Medici.' The continued intrigues of France in his states drove him into an Austrian alliance, which furnished Bonaparte with a pretext for declaring war simultaneously against Austria and Tuscany, and in 1801, at the peace of Lunéville, Ferdinand was forced to renounce all claim on Tuscany. The peace of Paris, however, reinstated him in Tuscany in 1814, and even restored his art-treasures. He died 17th June 1824.

Ferdusi. See FIRDAUSI.

Ferentino, a town of Italy, 55 miles by rail SE. of Rome. Portions of its ancient limestone walls are in the cyclopean style. Pop. 10,000.

Ferghana, a province in the SE. of Russian Turkestan, adjoining Eastern Turkestan, was formed in 1876 out of the khanate of Khokand (q.v.); area, 55,000 sq. m. In the N. are the Ferghana and Tchatkal ranges (part of the Tian-Shan); in the middle the lofty Alai Mountains and plateau and the Trans-Alai Mountains, with Kaufmann Peak (over 25,000 ft.); in the S. the Pamir (q.v.) covers 20,000 sq. m. The Syr-Daria traverses northern Ferghana, now the great cotton region of Russian Turkestan, and by irrigation canals fertilises a plain of some 13,000 sq. m. The population exceeds 2,000,000, more than half being Sarts, one-fourth Uzbeks, the rest Kirghiz, Tajiks, &c., and a few Russians and Jews. The chief towns are the capital Skobelev or New Marghilan (pop. 16,000), Khokand (105,000), Old Marghilan; Namangan and Andijan (Transcaspian railway termini); and Osh (50,000). See TURKESTAN.

Ferguson, ADAM, a Scottish philosopher and historian, was born 20th June 1723 at Logierait, in Perthshire, of which parish his father was minister. He studied at the universities of St Andrews and Edinburgh, and was appointed in 1745 for his

knowledge of Gaelic chaplain to the famous Black Watch, in which capacity he was present at the battle of Fontenoy, and is said to have charged the enemy sword in hand among the foremost. In 1757 he succeeded David Hume as keeper of the Advocates' Library in Edinburgh, and was next appointed professor in the Edinburgh University, first of Natural Philosophy (1759), and subsequently (1764) of Moral Philosophy—a subject much more to his mind. While holding this office he accompanied the young Earl of Chesterfield (1774) on his travels on the Continent, and acted as secretary to the commission sent out by Lord North to try to arrange the disputes between the North American colonies and the mother-country (1778-79). The state of his health compelled him in 1785 to resign his professorship, in which he was succeeded by Dugald Stewart, who had previously been his deputy; but he was appointed to Dugald Stewart's own chair of Mathematics, and allowed to discharge its duties through Playfair. He next travelled on the Continent, and after his return lived a while at Neidpath Castle in Tweeddale, then farmed fourteen years at Hallyards in the vicinity. His last years he spent at St Andrews, where he died 22d February 1816. Ferguson gave up at fifty the convivialities of his time, and reaped the benefit in the unusual health and mental vigour he enjoyed to the last. Scott and Lord Cockburn have left graphic descriptions of the fine old man that reveal a love for his own virtues no less than mere admiration for a monument of the past. It was in his house that the boy Scott had his one memorable glimpse of Burns. Ferguson's writings are his *Essay on Civil Society* (1766), *Institutes of Moral Philosophy* (1772), *History of the Progress and Termination of the Roman Republic* (1782), and *Principles of Moral and Political Science* (1792). His *History of the Roman Republic* was long a standard authority on its subject, was translated into both French and German, and was recommended by Carlyle in his rectorial address at Edinburgh as 'particularly well worth reading.' See Memoir by John Small (1864).

Ferguson, JAMES, a self-taught Scottish astronomer, was born near Rothiemay, in Banffshire, 25th April 1710. His father being a poor day-labourer, he enjoyed only three months of instruction at school, and his subsequent acquirements were the result of his own insatiable thirst for knowledge. His natural bent was chiefly towards practical mechanics and astronomy; and while keeping sheep, to which he was sent at ten, he was constantly busy in making models of spinning-wheels and mills, and at night in mapping the stars with a stretched thread and beads strung upon it. After working some years at cleaning clocks, making sun-dials, and the like, he took to drawing patterns for embroidery and copying pictures and prints with pen and ink. He then supported himself and his parents by drawing portraits, first in Edinburgh, and after their death in London; his leisure time being all the while given to making orreries, and to other astronomical pursuits. In 1748 he began lecturing on astronomy and mechanics with great acceptance. In 1761 he received from George III. a pension of £50, and he was elected F.R.S. two years later. He now gave up portraits, and devoted himself to lecturing throughout the country, and to writing on his favourite subjects with an assiduity unbroken by unhappy domestic circumstances. He died in London, 16th November 1776. Ferguson's principal works are *Astronomy explained upon Sir Isaac Newton's Principles* (1756; 13th ed. revised by Sir David Brewster, 2 vols. 1811), and *Lectures on Mechanics, Hydrostatics, Pneumatics, and Optics* (1760; also edited by Brewster, 1805). See the

Life by Dr Ebenezer Henderson, with an Autobiography (1867; 2d ed. 1870).

Ferguson, PATRICK, inventor of the breech-loading rifle, was born in 1744 at Pittour, Aberdeenshire, and, entering the army in 1759, served in Germany and Tobago. In 1776 he patented his rifle, firing seven shots a minute, and sighted for ranges of from 100 to 500 yards; and with it he armed a corps of loyalists, who helped at the battle of Brandywine (1777) to defeat the American army. He himself had a chance there of picking off an officer, but 'let him alone, disgusted with the idea of firing at the back of an unoffending individual, who was acquitting himself very coolly of his duty.' Next day he learned that the officer was Washington. Three years later, on October 7, 1780, Major Ferguson fell, defending King's Mountain, South Carolina, with 800 militia against 1300 Americans. This affair, which was not unlike that of Majuba Hill, turned the tide of southern warfare. See James Ferguson's *Two Scottish Soldiers* (Aberdeen, 1888).

Ferguson, ROBERT, the 'Plotter,' was born about 1637, near Alford, in Aberdeenshire, and in 1662 was ousted as a Presbyterian from the Kentish vicarage of Godmersham. As Shaftesbury's right hand, as Monmouth's 'evil genius,' he played for ten years a leading part in every treasonable scheme against the last two Stuart kings, and twice had to flee the kingdom. But after the Revolution, of which in 1706 he published a History, he changed sides, and conspired as busily for the losing Jacobite cause. He died, wretchedly poor, in 1714. His younger brother, James, commanded a brigade at Blenheim, and died very suddenly at Bois-le-Duc in 1705. See *Ferguson the Plotter* (1887), by James Ferguson, and his *Two Scottish Soldiers* (1888).

Ferguson, SIR SAMUEL, poet and Celtic scholar, was born at Belfast in 1810, educated at Trinity College, Dublin, and called to the bar in 1838. He gave himself more to Irish antiquities than to law, and in 1867 was appointed the first Deputy-keeper of Records in the Four Courts, in which capacity his qualities of organization and arrangement were conspicuous. As president of the Royal Irish Academy he gave a powerful impetus to the scientific study of early Irish art, and its *Transactions* contain many invaluable papers from his pen. In 1878 he was knighted, and on 9th August 1886 he passed away (see the Life by his wife, 1896). His musical and spirited poems, steeped in the truest patriotism, early began to appear in *Blackwood's*, the *Dublin University Magazine*, &c.; *The Forging of the Anchor* (1831); *Lays of the Western Gael* (1865); *Congal, a Poem in Five Books* (1872); *Poems* (1880). His edition of the *Leabhar Breac* appeared in 1876; his *Ogham Inscriptions* in 1887.

Fergusson, JAMES, D.C.L., F.R.S., 'the historian of architecture,' was born at Ayr in 1808, and after spending some years as an indigo-planter in Bengal, explored nearly every corner of India, sketching and studying the rock-temples, which were illustrated in his earliest works. His invaluable *History of Architecture* (4 vols. 1865-76; 3d ed. 1894), appeared first as a *Handbook* in 1855. He published works on fortification and on the defences of Portsmouth, and was a member of the Royal Commission on the defences of the United Kingdom. His other works include *The Palaces of Nineveh and Persepolis Restored* (1851), *Tree and Serpent Worship* (1869), and a *History of Jude Stone Monuments* (1872). He died 9th January 1896.

Fergusson, ROBERT, a Scottish poet, was born at Edinburgh, 5th September 1750, the third son of an industrious clerk from Aberdeenshire. A burrsary for boys of his name enabled him to get

a good education at Dundee grammar-school and St Andrews University, where he took to writing verses, and discovered his disinclination for the clerical life to which he had been destined. Medicine proving equally distasteful, he found employment at Edinburgh in the office of the commissary clerk, contributing the while to *Ruddiman's Weekly Magazine* poems which quickly gained him such local reputation as unhappily proved his ruin. His society was eagerly sought, and in that convivial time he was led into excesses which permanently injured his health. At last he fell into a religious melancholy, which became complete insanity after an injury to the head received in a fall down stairs. He died on the 16th October 1774, and was buried in the Canongate churchyard, where fifteen years later Burns, at his own expense, erected a memorial-stone with a poetical inscription over his grave. His poems were collected in 1773. There are editions by T. Ruddiman (1779), D. Irving (1800), Robert Chambers (1840), A. B. Grosart (1851), and Ford (1905). As a poet Fergusson possessed vigour, fancy, fluency in versification, and an original vein of comic humour, but lacked imagination, energy, and passion. Such poems as 'The King's Birthday,' 'Braid Claith,' and 'Leith Races' are remarkably happy in hitting off the ludicrous side of local manners; 'The Farmer's Ingle' has a more lasting interest as the prototype of 'The Cottar's Saturday Night.' Burns had an admiration for 'his elder brother in the Muses' out of proportion to his merits. Grosart's monograph (1897) is too eulogistic. See Fairley's *Bibliography* (1916).

Fergusson, SIR WILLIAM, surgeon, was born at Prestonpans, Scotland, on 20th March 1808. He studied medicine in the schools of Edinburgh, and was subsequently (1836) elected a surgeon in the infirmary. But in 1840 he left Edinburgh for London, having accepted the chair of Surgery in King's College, together with the post of surgeon in the hospital attached to the college. In 1866 he was made a baronet, in 1867 serjeant-surgeon to the Queen, and in 1870 he became president of the Royal College of Surgeons, London. He died in London on 10th February 1877. As a surgeon he proved himself a fit rival to Liston and Syme, performing his operations with great boldness, skill, celerity, and coolness. He especially distinguished himself in cases of stone, cleft palate, diseased leg and arm bones, diseased jaw, tumour, and hare-lip. See H. Smith, *Sir W. Fergusson, a Biographical Sketch* (Lond. 1877).

Feriae, the ancient Roman term for holy days during which political and legal transactions were suspended, and slaves enjoyed a cessation from labour. *Feriae* were thus *dies nefasti*, the opposite of the *dies fasti*. Days which were consecrated to a particular divinity, on which any public ceremony was celebrated, and the like, were *feriae*. In contradistinction to these, which were *feriae publicae* or public holidays, there were *feriae privatae*, which were observed by single families in commemoration of some particular occurrence of importance to them or their ancestors. Birthdays, days of purification after a funeral, and the like, were also observed as family *feriae*. See **FASTI**.

Feringhee, a name applied in the East to Europeans, whose land is vaguely called *Feringistan*. The term is a corruption of Frank, and dates from the Crusades.—In Bengal the mixed descendants of the Portuguese, while differing only in religion from the natives, are especially distinguished by the title of *Feringhis*.

Perishtah. MOHAMMAD KASIM HINDU SHAH FIRISHTA, or FERISHTAH, a celebrated Persian historian, was born about the middle of the 16th century, at Astrabad, on the Caspian Sea. At a

very early age he went with his father to India, where we find him, when twelve years old, at Ahmednagar, in the Deccan. Here he afterwards became captain in the bodyguard of Murtaza Nizam Shah; and when this king was deposed by his own son, Ferishtah went to Bijapur (998 A.H., 1589 A.D.), where the reigning monarch received him with great honour. His death is supposed to have taken place shortly after the year 1612. His great work is the *Tarikh-i-Firishtha*, or History of the Mohammedan power in India, which he finished in 1018 A.H. (1609 A.D.). Twenty years were spent in its preparation, and, according to Ferishtah himself, thirty-five books were used for and partly embodied in it.

Fermanagh, a county of Northern Ireland, in the south-west of Ulster, 45 miles long by 29 broad; area, 714 sq. m., of which 166 are arable, 368 pasture, about 100 uncultivable, and 72 water (including Upper and Lower Lough Erne). The surface is mostly a succession of mountains and hills, culminating in Cuilcagh (2188 feet); the rocks include limestone, with many cavities and underground watercourses, Millstone Grit, and Old Red Sandstone. Some coal, iron, and marble occur. The principle river is the Erne, which traverses the county in the direction of its longest axis. The soil in the low grounds is a deep rich loam, but in the limestone and sandstone districts it is cold and thin. The climate is mild and moist, though healthy. The chief products are oats, barley, wheat, potatoes, turnips, and hay; the chief exports, oats, butter, and eggs; and a little coarse linen is manufactured. Fermanagh returns two members to Westminster, and, with Tyrone, seven to Belfast. Pop. (1851) 116,047; (1871) 92,794; (1901) 65,443; (1911) 61,836, more than half Roman Catholics. Enniskillen is the county town. Among the antiquities are a round tower and St Mary's Abbey on an island in Lough Erne, Danish mounds, and ruined castles.

Fermat, PIERRE DE, a French mathematician, was born at Beaumont de Lomagne, near Montauban, in 1601, and at an early period, in conjunction with his friend Pascal, hit upon a very ingenious mode of considering figurate numbers, upon which he subsequently based his doctrine of the calculation of probabilities. Fermat employed himself greatly with the properties of numbers, and made many acute discoveries in regard to their composition and analysis. He also squared the parabola in a much simpler way than Archimedes at an earlier period had done, and made many other discoveries in geometry. His method of finding the greatest and least ordinates of curved lines was analogous to the method of the then unknown differential calculus. In addition to his scientific attainments Fermat possessed an extraordinary knowledge of ancient and modern languages. He died at Toulouse, 12th January 1665. A collection of Fermat's works appeared at Paris in 1670-79.

Fermentation.—The term fermentation (Latin, *fervere*, to boil) was originally applied to all chemical processes which were accompanied by frothing or effervescence due to the escape of gas from a liquid, and it was only after the discovery and discrimination of the various kinds of gas, in the time of Priestley, that the word 'fermentation' was limited to alcoholic fermentation—the mysterious change which occurred spontaneously when liquids containing sugar were exposed to the air, or could be artificially induced, as in brewing, by the introduction of yeast into the saccharine extract. Fermentation was regarded as a purely chemical process, and yeast as a chemical precipitate; even after the discovery in 1837 that yeast was a living organism (see **GERM THEORY**), Liebig long maintained the current opinion, until van-

quished by the new facts revealed by the researches of Pasteur (1857-60). The great French investigator showed that just as alcoholic fermentation—the conversion of sugar into alcohol and carbon dioxide—was caused by yeast, so many other characteristic changes undergone by organic matter were also caused by micro-organisms. To take a familiar instance, the souring of milk, due to the production of lactic acid from the milk-sugar, was termed the lactic acid fermentation, and was traced to the agency of a bacillus which was termed the lactic acid ferment. The less familiar production of butyric acid from milk by the aid of rancid cheese was also traced to a bacillus—the butyric acid ferment—and the idea was established that many different micro-organisms existed, each capable of bringing about a characteristic chemical change or fermentation. All these agents were living organisms, and were therefore termed *organised ferments*. Their effects followed on the introduction of a minute trace of the living material, were accompanied by the growth and ceased with the death of the organism, and were generally recognised as being inseparable from the vital manifestations of the cell. ‘Without life, no fermentation,’ was the dictum of Pasteur, which summed up the opinion of the scientific world almost to the end of the 19th century.

Other remarkable changes had, however, long been known which were brought about by materials elaborated in plants and animals, and were also characterised by the facts that a very large amount of change could be effected by a very small amount of the material and that the agent was destroyed by heat. Such were the digestion of meat by the Pepsin (q.v.) of the stomach, the conversion of starch into sugar by the Diastase (q.v.) of malt, and the ‘inversion’ of cane-sugar by the invertase of yeast. In these cases, however, the agents could be extracted from the organisms in which they were produced, and were termed at first *unorganised ferments* and later (Kühne) *enzymes* (Greek—in leaven or yeast).

The sharp distinction drawn between agents producing very similar effects seemed to many minds improbable, and the theory was advanced (Traube, 1858) that all these actions were really due to enzymes, which in the case of the organised ferments could not readily be separated from the cells of the organism. Experimental proof of this theory was, however, lacking until E. Buchner in 1897 succeeded in preparing from yeast a liquid which, in the complete absence of all living cells, was capable of bringing about the alcoholic fermentation of sugar. Evidence of a similar, if somewhat less cogent, nature was later found to show that the characteristic effects of certain bacteria (the lactic and acetic fermentations) were also due to the presence of enzymes, and the result of Buchner’s classical experiment has been that we are now able to say with some degree of confidence that the fermentations produced by living organisms are brought about by the aid of enzymes (or ferments).

Nature and Mode of Action of Enzymes.—Many chemical changes are known in which simple inorganic substances play a part closely analogous to that taken by the more complex enzymes in the chemical transformations which proceed in living organisms. Such substances are termed *catalysts*, and their action, known as *catalysis*, is characterised, like that of enzymes, by the facts: (1) that they remain unchanged at the end of the transformation, and (2) that they bring about a very large amount of change relatively to their own weight or chemical equivalent. A single instance will suffice to illustrate the relations which exist. A solution of cane-sugar, when kept free from living organisms, may be preserved indefinitely or

may be boiled without undergoing any measurable degree of change. If, however, a small quantity of a strong acid, such as hydrochloric acid or sulphuric acid, be added, a remarkable change occurs slowly in the cold, very rapidly on heating, which results in the complete decomposition of the cane-sugar and the production of two new simple sugars known as grape-sugar (glucose) and fruit-sugar (fructose). The acid which has been added still remains in the solution unaltered, and can if necessary be removed by suitable means and used over and over again. In this case catalysis has been effected by a simple substance of perfectly well-known composition and constitution. Precisely the same change can be produced in the solution of cane-sugar by the action of an extract prepared from yeast, the cells of which have previously been killed. If this material be used, the solution cannot be boiled, as the agent is destroyed by heat. At temperatures of about 30°-50° C. (86°-122° F.), however, the change goes on rapidly and leads to the same result as when acid is used and the solution boiled. Moreover, the agent contained in the yeast extract can be separated from the resulting mixture of grape and fruit sugars (by dialysis) and used over and over again. The yeast extract, or some constituent of it, has in this case played precisely the part of the acid in the former experiment, i.e. it has acted as a catalyst.

Here, however, a very important point must be noticed. Whereas the acid added is a well-known simple chemical substance, the yeast extract is a mixture of different substances, some of a very complex and up to the present unknown constitution. Experiment has shown that the catalytic power is associated with some substance contained in the extract which has several properties, by the aid of which it can be roughly separated from the other constituents of the mixture. Thus it can be precipitated by alcohol, and when dissolved in water will not pass through parchment paper. In this way a concentrated preparation can be obtained which has the original catalytic properties of the extract. This preparation and the original extract are both said to contain the enzyme, but it has so far proved impossible to isolate the enzyme and recognise it as a definite pure chemical compound. It remains known to us only by its power of producing the characteristic change in cane-sugar solution. This is true, at the moment, of all enzymes, and the various preparations made and sold as enzymes and ferments (such, e.g., as pepsin, trypsin, pancreatin, &c.) are simply mixtures which bring about certain characteristic changes and, presumably, contain more or less of the enzyme in question. The enzymes themselves still remain unknown to us.

The conditions of animal and vegetable life impose a very remarkable limitation on all chemical changes which proceed in living organisms. The temperature must not rise beyond a certain comparatively low point, and no strong acids or alkalis or other powerful reagents can be employed, since, with few exceptions, living cells are killed at a temperature of about 50°-60° C. (122°-140° F.), and are rapidly destroyed by acids and alkalis. Hence we find that in living cells agents (the enzymes) are present, by means of which the most complex chemical changes can be brought about at low temperatures, the imitation of which in the laboratory by the aid of ordinary chemical methods often involves the use of high temperatures and powerful reagents which would be instantly fatal to life. Enzymes, therefore, are the agents by which chemical changes are brought about in living organisms. These chemical changes are of two chief kinds, since, in all living matter, two processes are constantly proceeding—the forma-

tion of the complex material of the cell from simple substances (termed chemically synthesis, or physiologically anabolism), and the decomposition or breaking down of these complex materials into simple substances which are excreted (termed chemically analysis, and physiologically katabolism).

Enzymes are active in bringing about changes of both kinds, and in very many cases it has actually been proved that the same enzyme can produce a change in either direction according to the conditions which prevail. Thus the same enzyme (lipase) which, in the process of digestion in the animal intestine, converts emulsified fats into glycerol and fatty acid, can also produce the reverse change, and from fatty acids and glycerol build up fat, the condition necessary for this second change being the presence of a relatively large proportion of glycerol and only a small proportion of water.

Extraction of Enzymes.—Enzymes are, as a rule, secreted by special cells, and in some cases pass out of the cell and become mixed with the material upon which their activity is to be exerted. In other cases they remain within the cell, but can frequently be extracted by means of water, glycerol, or dilute acids. It is usually necessary to kill the cell before carrying out such extractions, and in some cases the enzyme can only be removed by rupturing the wall of the cell by grinding with sand and pressing out the contents.

Types of Fermentation or Enzyme Action.—The changes which are brought about by the aid of enzymes comprise practically the whole series of chemical transformations which occur in living organisms, and it is therefore not surprising to find that a very large number of enzymes are known. Each enzyme is only capable of bringing about one kind of change, and, further, can only affect one particular class of substances chemically very closely allied, or, in some cases, only a single substance. They differ in this respect most markedly from inorganic catalysts, by the aid of many of which the most diverse substances can be attacked. The process of digestion affords many instances of this difference. Three constituents of food—fats, proteins, and starch—are all broken up into simple products by the digestive enzymes before being absorbed. In the body a special enzyme, or rather series of enzymes, is required for each of these substances; the fat-splitting enzyme (lipase) has no action on starch or protein, the enzyme which saccharifies starch (diastase) has no effect on fat or protein, and those which digest protein (pepsin, trypsin) leave both fat and starch unaltered. Chemically all these three substances can be broken up by one method—boiling with acid—the products being essentially the same whether enzyme or acid be used. So far does this specialisation go, that even the different sugars, e.g. milk-sugar and cane-sugar, require different enzymes (lactase and invertase) for their decomposition, lactase being quite without action on cane-sugar, and invertase quite indifferent to milk-sugar.

I.—The first great group of enzymes comprises those concerned in the breaking up of complex substances by addition of water into simple compounds, a process termed *hydrolysis* (Greek, 'breaking up by water'); $AB + H_2O = A.OH + BH$, or conversely, building up complex substances from simple constituents with removal of water $A.OH + BH = AB + H_2O$, a chemical change known as *condensation*.

Reference has already been made to some of these enzymes. *Lipase*, which decomposes fats into glycerol and a fatty acid, occurs in the animal body (see DIGESTION), and in a large number of seeds in which it decomposes the reserve of fat

and renders it assimilable by the growing seedling. The lipase of the castor-oil bean is used on a large scale for the decomposition of fats for soap-making. The enzymes which act on the carbohydrates (sugars and substances which yield sugars when hydrolysed) are extremely numerous, and occur both in the animal body and in seeds, and are widely distributed in plants. Among them are Diastase (q.v.), which converts starch into the sugar known as maltose, invertase, and lactase, which respectively decompose cane-sugar and milk-sugar, maltase and many others. The enzymic decomposition of the proteins is a very complicated process (see DIGESTION), which probably involves the successive action of a considerable number of enzymes. The best known are Pepsin (q.v.), which occurs in the stomach and only acts in acid solution, and trypsin, which is found in the animal intestine and produces its effect in an alkaline medium.

II.—A second group of enzymes brings about a change, the nature of which is not quite understood, although the change itself is of the greatest importance. These are the coagulating enzymes or *coagulases*. The effects of two of these are very familiar. The first causes the formation of a curd in milk, and is known as Rennet (q.v.) or rennin. The second, known as thrombase, produces the coagulation of the blood, a soluble constituent of which (fibrinogen) is converted into an insoluble form (fibrin), a clot being thus formed. A third enzyme of this group is known as *pectase*, and is of great importance in vegetable life, since it assists in the building up of the skeleton of plants.

III.—A fundamentally important chemical change, which occurs in both the animal and vegetable organism, is oxidation, a process in which the various tissues and foodstuffs undergo a slow combustion in the oxygen of the air into simple products, with the result that energy is liberated available for the uses of the organism, and ultimately heat is produced. Unfortunately comparatively little is yet known of the exact mechanism by which this complete oxidation is brought about. In both the animal and vegetable organism, however, a number of enzymes have been discovered which have a limited power of oxidation, and can transfer oxygen either from the air or from some compound containing it to the substance undergoing oxidation. In many cases the product of partial oxidation is coloured, familiar instances being the brown colour developed on cut apples or pears, the blackening of leaves injured by frost, the blue colour produced when certain fungi are broken, and the colours of some flowers. Such enzymes are termed *oxydases* and *peroxydases*, and others are known which remove oxygen from its compounds and are called *reducases*.

IV.—Another very widely diffused enzyme has the remarkable function of liberating oxygen in the free state from hydrogen peroxide, and is known as *catalase*. This enzyme occurs in blood and most animal tissues, as well as in plants. Its function is not definitely known, but is probably that of decomposing hydrogen peroxide formed in the various oxidation processes of the living organism. So widely spread is it, in fact, that at one time it was thought that all enzymes had the power of decomposing hydrogen peroxide, and it was only gradually found that this was not the case, but that this property was confined to one specific enzyme.

V.—Enzymes belonging to all the previous groups may, and do, occur not only in the higher plants and animals, but in every form of living cell, however simple. Many organisms which consist of a single cell (unicellular), such as bacteria and yeasts, possess in addition the power of producing

very extensive chemical changes of a somewhat different kind from those already considered. These consist in the rearrangement of the elements of some complex substance in such a way that simple compounds are formed, and, this being the essential point, energy is rendered available for the organism. In some cases the organisms live without oxygen (anaerobic bacteria), and the only source of energy is the fermentation of some constituent of the medium in which they grow. In other cases oxygen plays much the same part as with the higher animals and plants, but the power of fermentation is also exercised.

Alcoholic Fermentation.—Of all the processes of this kind the best known and the most important economically is alcoholic fermentation. This ensues when 'yeast' is introduced into a liquid containing sugar and a supply of nitrogenous nutriment, and kept at a temperature somewhere between 0° and 30° C. (32° and 86° F.).

The Yeast (q.v.) used in brewing is a species of a particular genus (*Saccharomyces*) of the Fungi. It consists of a single cell, and increases by budding—a small protuberance appearing in the wall of the mother-cell and gradually increasing until a new cell is formed, which ultimately separates. Both cells then form buds, and so the growth continues. A very large number of genera and species belonging botanically to the same family (*Saccharomycetaceae*) are known, and many, but not all, of these produce alcoholic fermentation in greater or less intensity. Some species of closely allied organisms belonging to other families (the *Torulaceae* and *Schizosaccharomycetaceae*) also possess the power of alcoholic fermentation, which is in addition characteristic of some of the higher fungi (e.g. *Mucoraceae*). In all these cases the course of alcoholic fermentation is similar, although the intensity of the process varies very greatly. When a single cell of yeast is introduced into a suitable medium it commences to grow and rapidly increases by budding. During the growth a small proportion of the sugar is used as food for the building up of the tissue of the new cells, but by far the greater part is decomposed into alcohol and carbon dioxide. At the same time the nitrogenous constituents of the medium are decomposed, and the resulting ammonia is assimilated by the organism and built up into the protein constituents of the cell. The other products of decomposition of these nitrogenous materials remain in the medium and are found in all fermented liquors. They consist of various alcohols (fusel oil) and acids (succinic acid, &c.), and are of the highest importance with regard to the taste and smell of the product. It was formerly thought (Pasteur) that these substances were formed from the sugar, but it has now been clearly proved (Felix Ehrlich) that they are derived from the nitrogenous constituents of the medium, and vary according to the nature of this. The flavour of fermented liquors therefore varies with the source of the nitrogenous material employed. The alcohol and carbon dioxide are, however, accompanied by a small and variable proportion of glycerol (about 3 per cent.), which is formed from the sugar. The remainder of the sugar is converted quantitatively into alcohol (51 per cent.) and carbon dioxide (49 per cent.), almost equal weights of the two being formed.

The range of substances which can be fermented by yeast is very limited. With the exception of one or two artificially prepared simple compounds, the only substances directly fermented by yeast are the simple sugars—grape-sugar, fruit-sugar, the less known galactose (derived from milk-sugar), and mannose. In addition to this, however, the naturally occurring more complex sugars (and a few other compounds), which yield the foregoing

when boiled with acids, are also fermented. Such are cane-sugar, which yields grape-sugar and fruit-sugar; maltose, yielding grape-sugar alone; milk-sugar, yielding grape-sugar and galactose. With respect to these sugars, however, the different yeasts may vary considerably, some, such as the ordinary brewing yeasts, fermenting cane-sugar and maltose but not milk-sugar, others cane-sugar but neither of the other two, and so with the rest. The reason of this is of great interest. It is that these complex sugars are not directly fermented by yeast, but are first split up into the simple fermentable sugars, in each case by the special enzyme (see *ante*) required. Yeasts which ferment cane-sugar contain invertase, those which do not attack cane-sugar are quite devoid of invertase.

It was early discovered that the whole of the fermentation process occurs inside the yeast-cell, the liquid outside the cells being at all stages of the process incapable of producing fermentation. The sugar diffuses into the cell and there undergoes fermentation, and the alcohol and carbon dioxide diffuse back out of the cell into the surrounding medium, where the alcohol remains, whilst the carbon dioxide, being produced in far greater quantity than is necessary to saturate the liquid, is mainly given off as gas.

All attempts to obtain a preparation from yeast which should ferment sugar in the absence of yeast-cells failed until, in 1897, E. Buchner succeeded by grinding the yeast for a short time with sand and kieselguhr to rupture the cell-membranes, and then removing the liberated cell-juice (cytoplasm) by means of a filter-press. Since then it has been found possible (Lebedev) to obtain a similar preparation in many cases by drying the yeast and then simply digesting with water at about blood heat for a few hours and filtering. Obtained in either way the liquid brings about active fermentation of sugar into alcohol and carbon dioxide, but at a much slower rate than the living yeast from which it was prepared. Thus was decided one of the great scientific controversies of the 19th century—Can fermentation proceed without life? The yeast-juice of Buchner contains the enzyme which brings about alcoholic fermentation, and to this has been given the name *zymase*. Further study of the properties of the juice has, however, shown (Harden and Young, Neuberg) that the process of fermentation is much more complex than had been anticipated from the phenomena exhibited by living yeast. The whole phenomenon is dependent on the presence of mineral phosphates, and cannot proceed in their absence, and the production of carbon dioxide and alcohol probably represents the final stage of a series of reactions. It seems quite certain that the alcohol is formed by addition of hydrogen to pre-formed acetaldehyde. If this substance is protected from reduction (Neuberg's fixation method) by the addition of sodium sulphite, it is found among the final products, and a corresponding quantity of glycerol is produced by the reduction of another intermediate product. Glycerol was thus manufactured in Germany from starch when the supply of fats failed. Further, yeast-juice is an instance of a peculiarity exhibited by several enzymes. It contains two agents, both of which are required for fermentation. One—termed the enzyme—is more complex than the other, is inactivated by heat like all other enzymes, and cannot pass through parchment paper. The other is of simpler character, is not inactivated by heat, and can readily pass through parchment paper. To indicate its function as a coadjutor of the enzyme it is termed the *co-enzyme*, but its real nature is as little known as that of the enzyme itself. The two can readily be separated and two solutions obtained, neither of

which will ferment sugar, whereas the mixture of the two has a vigorous action.

Bacterial Fermentation.—Many Bacteria (q.v.) produce characteristic fermentations, which are of the most varied type and may affect sugars, fats, proteins, and many comparatively simple compounds. In general, very little is known of the mechanism of these fermentations, but it has been proved in several cases (e.g. lactic acid and acetic acid fermentations) that the organism effects the change by means of an enzyme, and it is probably a fair conclusion that all bacterial fermentations are enzyme actions. Perhaps the best known example is the lactic acid fermentation, in which sugar is converted almost quantitatively into lactic acid. This process is used commercially for the production of lactic acid, and is the chief change which occurs in the souring of milk. The organisms of the butyric fermentation convert sugar into a complex mixture of substances, prominent among which is butyric acid. Some organisms of this class yield a large proportion of butyl alcohol, at one time proposed as a commercial source of rubber, and acetone, prepared during the Great War in this way for use in the production of cordite. The cellulose fermentation, by which the cellulose of vegetable remains is ultimately broken up in the soil into hydrogen or marsh gas (according to the special organism) and carbon dioxide is of great importance as forming one stage in the 'carbon cycle' in nature. Other important fermentations are the oxidation of alcohol to acetic acid (manufacture of vinegar), and the conversion of ammonia in the soil by the aid of oxygen into nitrous acid and ultimately nitrates. The bacterial decomposition of proteins is also effected by many bacteria. It occurs wherever albuminous matter is exposed to infection from the air, and is then known as Putrefaction (q.v.).

Fermo, a town of Italy, is situated on a rocky height 4 miles from the Adriatic, and 36 SSE. of Ancona. It is well built, is surrounded with ancient walls, and has been the seat of an archbishop since 1589. Formerly Fermo possessed a university. Pop. 20,000. Its port, Porto San Giorgio (pop. 5000), on the Adriatic, has some trade in corn, silk, and wool. In the immediate vicinity of Fermo are the ruins of the ancient *Firmum*.

Fermoy, a clean, well-built town in County Cork, Ireland, on the Blackwater, 19 miles NE. of Cork city. Its origin dates from the 12th century, when it was the seat of a Cistercian abbey; but the present town was the creation of a Scottish merchant toward the close of the 18th century. It contains a Catholic cathedral, St Colman's College, and barracks. The river is crossed by a noble stone bridge, erected in 1866. The town has a trade in flour and agricultural produce. The population is about 7000.

Fern. See FERNS.

Fern, MALE, *Aspidium* (*Nephrodium*) *filix-mas*, a name given by old herbalists in contrast to the Lady Fern, *Asplenium* (*Lastræa*) *filix-femina*, which, from the aspect of their foliage and common association in woods, they imagined to represent the two sexes. The large subterranean rhizome contains a volatile oil, to which the long-established medicinal value as a vermifuge (particularly in tapeworm) is due.

Fern, SWEET (*Comptonia asplenifolia*), an ill-named shrub of the sweet gale family (Myricaceæ; see CANDLEBERRY, BOG-MYRTLE), a native of the mountain-woods of North America, forming a small bush with linear, pinnatifid, fern-like leaves. Its leaves have a powerful aromatic fragrance when rubbed. It is tonic and astringent, and is used as a domestic remedy for diarrhoea.

Fernandina, a port of entry and capital of Nassau county, Florida, on an island 28 miles NNE. of Jacksonville, forms a terminus of the railway connecting the Atlantic with the Gulf of Mexico, and has a considerable transit trade with the West Indies, Charleston, and Savannah, its shipments of lumber being especially great. It is a popular bathing resort. Pop. 5500.

Fernando Noronha, a volcanic group of one large island (6½ miles by 2) and several small ones, belonging to Brazil, in the South Atlantic, 200 miles ENE. of Cape San Roque. The islands are fertile and thickly wooded. They were visited by Cook in 1775, Darwin in 1832, and the *Challenger* Expedition in 1873.

Fernando Po, an island on the west coast of Africa, in the Bight of Biafra, with an area of 1185 sq. m., forms geologically a continuation of the Cameroon Mountains of the mainland. The island, oblong in shape, with steep, rocky coasts, and disposed in a NNE. direction, is bisected by 2° 39' N. lat. Its northern half is almost entirely occupied by the volcanic peak (10,000 feet) known to the English as Mount Clarence, to the Spaniards as Pico Santa Isabel; and its southern half contains a short range lying E. and W. The island is covered with luxuriant vegetation. The average annual temperature at Santa Isabel, the capital (pop. 1500), is 78° F. The island is inhabited by the Bubi, a Bantu tribe, and by some negroes. Cocoa, coffee, coconuts, copra, palm-oil, and palm-kernels are the principal products. Discovered by the Portuguese Fernão do Pao in 1472, the island has belonged to Spain (1777-1827), England, and Spain (since 1841). Pop. 12,000.

Ferne Islands. See FARNE ISLANDS.

Ferney, a village in the French department of Ain, 4½ miles NW. of Geneva, and 2 miles W. of the lake. It is celebrated as the place where Voltaire resided during the last years of his life. He purchased the estate in 1758, and from that time was known variously as the seigneur, the philosopher, and the patriarch of Ferney. During these years Voltaire acted as a dictator of letters throughout French-speaking Europe, and his château was a kind of pilgrimage resort for all sorts and conditions of literary and political celebrities.

Ferns (*Filices*), as the most abundant and beautiful, most varied and typical class of higher (i.e. Vascular) Cryptogams, are of special interest

alike to the botanist, the horticulturist, and the lover of nature. While Linnaeus included under his Filices all the Vascular Cryptogams, since Jussieu the equisetums, rhizocarps, club-mosses, and selaginellas have been separated off as distinct classes (see HORSETAIL, WATER-FERNS, LYCOPODIUM, SELAGINELLA, ISOETES), and by some modern authors the Ophioglossæ (see MOONWORT) also.

Since what we familiarly call the fern-plant is only the spore-bearing member of two alternating generations, it is convenient for the comprehension of the life-history of the group, and still more for comparison with that of the other above-named Vascular Cryptogams, and of these with

Gymnosperms (q.v.) and Phanerogams (q.v.), to begin with the minute fern-spore, and trace its history round to the spore again, although necessarily only in the briefest outline. In fig. 1, A, this double-walled and characteristically formed and marked spore is represented; in B it is germinating into a short filament which soon broadens into

a thin, flat, bilobed cellular expansion, the *prothallus*, C. This develops unicellular root-hairs from the under surface, and grows to a size varying on the average from $\frac{3}{8}$ th to $\frac{5}{8}$ th of an inch in diameter, resembling most nearly a small thallus of Liverwort (q.v.). It leads a perfectly independent existence, usually for several months, but

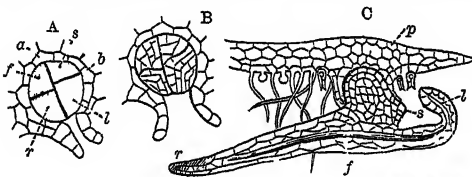

Fig. 3.

sooner or later develops organs of sex, of which both are most commonly present upon the same prothallus. Near the apex of the prothallus we find the female organs or *archegonia*, each archegonium being a flask-shaped group of cells, of which the deepest central cell enlarges greatly to become the ovum, which fills the body of the flask, while those above it undergo mucilaginous degeneration and disappear, so leaving the neck of the flask as an open way of access to the egg-cell from the exterior (fig. 2, A-D). The male organs (*antheridia*) arise as epidermic papillae among the root-hairs, and divide into spheroidal groups of cells inclosing a large central cell, which soon segments into a group of spermatocytes (see fig. 2, E-G). These undergo maturation, and escape in the ciliated state as free-swimming spermatozooids, which in surface moisture, caused

by rain or dew, find their way towards the archegonia. One spermatozoid suffices to fertilise an egg-cell, and, however many archegonia may be fertilised, the small prothallus is only able to bear a single fern-plant. The fertilised ovum segments into four portions (fig. 3, A-B), of which two divide to form the so-called *foot*, by which the young fern remains for

a time attached to and nourished by the parent prothallus (fig. 3, C); another goes on dividing to form the first root, while the remaining one gives rise to the stem and leaf. As the fern grows it slowly exhausts the prothallus, which dies off and disappears, and the fern gradually assumes the familiar vegetative development characteristic of the group.

The fern-stem and leaves grow by an apical cell (fig. 4, D); the root tip, too, has its apical cell, which also develops a root-cap (fig. 4, E). In the mass of embryonic tissue produced by the segmentation of the apical cell we soon distinguish (a) an external *dermatogen* layer which

gives rise to the epidermis and its outgrowths, (b) internal strands of tissue of which many cells undergo characteristic modifications and give rise to the future fibro-vascular bundles, the whole lying imbedded in (c) the less modified ground tissue, which for the most part remains parenchyma-

matous, but may in part become lengthened and hardened (as sclerenchymatous and prosenchymatous tissue), mainly for the purpose of increased mechanical strength. The fibro-vascular bundles form a meshwork anastomosing where bundles are given off into the leaves; they are closed and definite—i. e. contain no cambium and are consequently incapable of continued growth, save by addition at the growing-point. Their structure is usually concentric, the bast surrounding the wood. The axis forms most commonly a short root-stock; this, however, in some genera grows erect to a considerable height, as in the tree-ferns (see TREE-FERN), and in many species of *Pteris*, *Davallia*, *Polypodium*, &c., the rhizome is long and creeping. The leaves are developed in a close spiral succession just behind the growing-point, and are of slow growth, usually requiring two years to mature. Even in the expanded leaf growth may continue for a long time, the indefinite growth of the twining leaf of *Lygodium* being only the extreme case of this. Their peculiar *circinate vernation*—i. e. inrolled spiral or crozier-like folding in the bud—is very characteristic, and, as this must arise by a greater growth of the under than the upper surface, so the expansion of the leaf can be readily observed to be due to the gradual reversal of the disproportion, equilibrium being only reached with maturity. The leaf is sometimes entire, but is more frequently pinnate, bipinnate, or decomposed: this arises, however, in a somewhat different way

FIG. 6

A, Tasselled variety of Male Fern (*Adiantum*, var. *Cristatum*). B, Fertile frond of Royal Fern (*Osmunda regalis*).

from the pinna-
tion of the leaves
of phanerogams
(see LEAF), being
due to a dichotomy with unequal development of either fork alternately. The leaf-stalk or rachis is thus a false axis. The mode of origin is well revealed by reference to those tasselled varieties (fig. 6, A) which so frequently appear in widely distinct species in cultivation, exuberantly vegetative conditions admitting of the almost equal development of many successive secondary axes.

The production of sporangia and spores is in most ferns carried on by all the leaves indifferently (whence the attempt formerly so prevalent, but botanically unnecessary, to distinguish them from ordinary leaves as *fronds*). In many cases, however, this becomes restricted to particular portions of the leaf, apical in the common royal fern (*Osmunda regalis*, fig. 6, B), or median as in *O. interrupta*, or even to special fronds, as in the common hard fern (*Blechnum spicant*) or the parsley fern (*Allosorus crispus*). In such cases the vegetative development of the spore-bearing fronds is of course greatly checked, and we have a distinct foreshadowing of the stamens and carpels of the phanerogams (although the spores have not as yet themselves acquired any character of distinct sex, much less the sporangia and the leaves which bear them). The fern may also exceptionally bud directly from the prothallus without archegonia (*apogamy*), or the prothallus from the frond without spores (*apospory*). Many ferns (particularly *Asplenium*) also multiply directly by budding upon the fronds.

At fig. 5, A, we have a fertile pinna of the common male fern (a name which, of course, refers merely to an old misinterpretation of the contrast of its rough foliage with that of the lady fern), showing the groups or *sori* of spore-cases. The same figure (B) gives a section of a sorus, with developing sporangia under its epidermic cover or *indusium*. The sporangia (B, C) grow from epidermal or sub-epidermal cells, and at maturity contain about 64 spores, which are often angular and dark-coloured (D). The spore-case is ruptured when ripe in various ways at once of practical interest and of high systematic importance, and the spores are thus diffused in great numbers to take their scanty individual chance of germinating as new prothallia.

Systematists vary somewhat as to the orders into which to divide this very large class, which includes about 150 genera and about 4000 living species, besides a great number of extinct forms. A convenient enumeration of these, however, may be taken as follows:—

A. Sporangia thick-walled and without ring, arising in the leaf-tissue, and not as epidermal hairs (trichomes). I. Marattiaceae—4 genera, with about 30 species in tropical America, Asia, and Oceania: *Marattia*, 10; ^{*} *Angiopteris*, 7.

B. Sporangia epidermal, with ring. (a) Ring indistinct. II. Osmundaceae—2 genera, 11 species, scattered through all regions: *Osmunda*, 7 (see ROYAL FERN); *Todea*, 4. (b) Ring well developed; 6 orders, distinguished by details of sporangial structure—viz. III. Schizaceae—4 genera, tropical: *Schizaea*, 14; *Aneimia*, 30; *Lygodium*, 30; *Mohria*, 2. IV. Gleicheniaceae—3 genera, tropical, 40 species: *Gleichenia*, 8; *Mertensia*, 30; and *Stromatopteris*, 1. V. Hymenophyllaceae (see FILMY FERNS)—3 genera, 200 species, chiefly tropical: *Hymenophyllum*, 80; *Trichomanes*, 120. VI. Cyatheaceae, chiefly Tree-ferns (q.v.)—6 genera, with about 170 species, chiefly of southern tropical and warm temperate zones: *Alsophila*, 60; *Hemitelia*, 30; *Cyathea*, 40; *Cibotium*, 6; *Dicksonia*, 20. VII. Parkeriaceae—2 genera, with only 2 species, *Ceratopteris thalictroides*, eaten as a vegetable in tropical Asia, and *Parkeria pteridioides*, found floating in tropical American waters. VIII. Polypodiaceae. While the preceding families contain the genera above named, and a few others less known, the Polypodiaceae constitute the great majority (nine-tenths) of the whole group, and are widely distributed through all regions of the globe, although chiefly in warm climates. Of the chief families of these abundant and often remarkable ferns the following is a brief summary:—

(1) Sorus not covered by indusium. (a) *Acrosticheae*, with sporangia uniformly scattered upon the back of the frond or part of it—5 genera, 200 species, mostly tropical American, East Indian, and Australasian: *Acrostichum*, 170; *Platyceium*, 8, the stag's-horn ferns familiar in greenhouses, and remarkable for their ecological adaptations. (b) *Polypodiæ*, or *Polypodies* (800 species), with sori variously arranged. (i.) Sori in streaks following the veins: *Gymnogramme*, 74, of which *G. chrysophylla* and *G. tartarea*, both West Indian, are cultivated as the Golden Fern and Silver Fern, names which well describe the characteristic beauty of the mealy wax which is so copiously secreted by glandular epidermic cells as to cover the lower surface. Sori in round or elliptical patches: *Polypodium*, 150, mostly tropical (see POLYPODY); *Phegopteris*, 70 (Beech Fern). Sori linear: *Ceterach*, of which the common Scaly Fern, *C. officinarum*, was long in repute as an astringent medicine. (ii.) Sori along the edge of the frond: may be continuous and uncovered

* The numbers following generic names indicate the approximate number of known species.

(*Notochlæna*), or covered by a false indusium produced by the infolded edge of the frond, which is continuous in *Pteris*, 120 (see BRACKEN), discontinuous in *Allosorus*, 34 (Parsley Fern), while in *Adiantum*, 108 (see MAIDENHAIR FERN), the patches of sori are developed upon an turned edge.

(2) Sori covered by indusium. (c) *Asplenieæ*, or Spleenworts (400 species), mostly tropical, with long or linear sori, with indusium arising laterally from above a vein: *Blechnum*, 50 (the Hard Fern); *Asplenium*, 300 (the Spleenworts); *Scolopendrium*, 8 (see HART'S-TONGUE). *Diplazum esculentum* furnishes an edible rhizome in the East Indies. (d) *Aspidieæ*, or Shield Ferns (250 species), with dorsal sori of rounded shape, with shield-shaped or kidney-shaped indusia: *Aspidium* (*Nephrodium*), a large genus (220 species), including the Male Fern (see FERN, MALE) and many other well-known forms. Minor genera are *Cystopteris*, 9 (the Bladder Fern); *Woodsia*, 11; *Stutliopteris*, 3. (e) *Davallieæ*, with sporangia on a tooth, or in a furrow of the leaf edge—4 genera, with 200 species, almost all tropical: *Davallia*, 112. For *Salvinieæ* and *Marsileæ*, see WATER-FERNS.

Fossil Ferns.—Although fossil ferns have been described from rocks of Silurian age, yet such remains are so fragmentary as to afford no positive evidence of their fern nature, and most palæophytologists now consider the majority of such fossils to be the remains of *Algae*. From the Carboniferous rocks, however, the evidence of fossil ferns in abundance is clearly authenticated by excellent casts, and by beautiful petrifactions, which, when prepared for the microscope by slicing the rock into thin sections, reveal the fern type of structure with marvellous completeness. Drawings and photographs of such ferns, and sections of them showing microscopical details, are given in the works by Williamson, Kidston, Scott, Caruthers, Renault, Grand'Eury, Gwynne-Vaughan, Potonié, Seward, Solms-Laubach, Bertrand, Sterzel, Zeiller, and others.

Until near the close of the 19th century it was a generally accepted idea that the Carboniferous period was an age of ferns. More recently, however, it has been absolutely proved that many of the fossils supposed to be the remains of ferns were in reality plants of a much higher organisation with fern-like foliage, but bearing seeds or structures closely approaching them. Such fossils have recently received great attention, because they appear to bridge over a wide gulf in the evolution of plants, filling, indeed, the gap between Cryptogam and Phanerogam, and they have received the general name of *Pteridosperms*. This epoch-making discovery caused a revolution in botanical circles, and led to a re-investigation of the whole of the fossil fern-like flora, and many so-called Carboniferous ferns were regarded with suspicion. Notwithstanding the change of opinion following the discovery just mentioned, it may still be said that ferns were undoubtedly abundant during Carboniferous times. What are perhaps the most elementary of such ferns have been grouped by Seward under *Coenopterideæ*, a term including the *Botryopteræ* and *Zygopteræ* of previous authors. These comprise such forms as *Botryopteris antiqua*, *Stauropteris burntislandica*, *Metaclepsydropsis duplex*, *Diplolabis pettycurensis*, &c., all of which occur in a limestone at the base of the Carboniferous rocks at Pettycur, S. Fife, and they may be considered among the most ancient examples of fossil ferns known to science in a petrified form revealing microscopical structure. In higher zones of the Carboniferous, and in more recent rocks, fossil ferns of higher types abound. Some of these are minute, resembling filmy ferns, others are gigantic

like the tree-ferns of New Zealand and Ceylon. During the progress of the vast epochs of time through which the world has passed, many types of ferns have entered the arena and vanished, leaving merely their fossil remains, or, as must have happened with the majority, nothing whatever as a memento of their existence. Other types, strange to relate, have persisted from Carboniferous times even to the present day, and among such may be mentioned the *Osmunda* type and the *Maia* type. From the imperfect preservation of the sori and sporangia, the precise systematic position of fossil ferns can rarely with much certainty be determined. See PALÆONTOLOGY.

Uses of Ferns.—Like other perennial stems and root-stocks, those of ferns contain a store of starch, and this becomes in many species of economic importance to communities which have not reached the agricultural stage. Foremost among these is the rhizome of *Pteris esculenta*, the Tara (q.v.) of the Maoris, to which may be added *Aspidium edule* of Nepal, while the *Cyathea medullaris* in New Zealand, *Angiopteris evecta* in the South Seas, and other tree-ferns yield a kind of sago. Survivals of this use of ferns, or reversion to it in time of famine, also occur among more advanced peoples (see BRACKEN), and developing fern fronds are occasionally still eaten as a kind of salad in northern countries. Before the epoch of chemical manufactures the common ferns were a convenient source of potash, and their fronds are still often gathered as bedding for cattle. Their astringency gave them also a place in medicine, but the syrup known as *Capillaire* (see MAIDENHAIR) and the occasional use of male fern as a vermifuge alone survive in modern pharmacy. The characteristic beauty of their foliage has, however, given them in recent times a place in horticulture so important, especially in England, as to be unreasonably compared to the historic *Tulipomania* (see TULIP) itself. The hardy ferns succeed well on shady rockwork, and the exotics under glass; their propagation, either by division of the root-stock (*Davallia*, &c.) or by sowing tolerably fresh ripe spores in saucers, kept moist and shaded under a glass (*Pteris*, *Adiantum*, &c.), is also easy. Many can be grown under a large bell-glass in rooms, or better in Wardian cases.

Various superstitions attach to ferns—the root of some kinds, for example, was in some places credited with the power of opening locks. By 'watching the fern' in solitude during the night of St John's Eve (24th June) one might hope to meet fairy benefactors, and receive a purse of gold; but the most widespread superstition is that fern seed, properly gathered, renders the bearer invisible. On the same eve of St John the fern puts forth at dusk a small blue flower, which soon disappears; and the wonderful seed, quickly ripening, falls at midnight, and should be caught in a white napkin. Fern seed is in some places a 'wish-seed,' enabling the bearer to attain his utmost wishes.

See works by Bower, Campbell, Christ, Seward, Heath, Drury, Scott, Lowe, Britten, De Bary, Goebel, Van Tieghem, Diels, Engler, Williamson, Sim, and others; also the several works on ferns by Sir W. J. Hooker (*British Ferns*, *Garden Ferns*, *Filices Exotice*, *Species Filicum*); and, for systematic studies, Smith's *Historia Filicum*; or general, for beginners, Moore's *British Ferns*. For particular genera and species and their culture, see Nicholson's *Dictionary of Gardening*, Bailey's *Cyclopedia of American Horticulture*, &c.

Fer Oligiste, a French name for *Hæmatite* (q.v.). See IRON AND STEEL.

Feronia, a genus of Rutaceæ. *F. Elephantum*, the sole species, is the wood-apple.

Ferozabad, Ferozepore. See FIROZABAD, FIROZPUR.

Ferrandi'na, a town of Italy, on a height above the Basento valley, 43 miles ESE. of Potenza by rail. Pop. 8000.

Ferrar, NICHOLAS, born in 1592, at fourteen entered Clare Hall, Cambridge, of which in 1610 he was elected fellow. He studied medicine, and travelled five years on the Continent (1613-18), then engaged in the business of his father, a London merchant, and in 1624 was returned to parliament. But in 1625 he retired to Little Gidding in Huntingdonshire, and founded there the religious community familiar to every reader of Mr Shorthouse's *John Inglesant*; next year Laud ordained him deacon. With his brother and brother-in-law and their families the community numbered some thirty persons, who with constant services and perpetual prayer combined the occupation of fine bookbinding. Nicholas himself died on 4th December 1637, worn out by asceticism; but the 'Arminian Nunnery,' which received two visits from Charles I. (in 1633 and 1642), was not broken up by the Puritans till ten years after his death. See the two lives, one by his brother John, edited by Mayor (1855), and *Nicholas Ferrar, his Household and his Friends* (1892).

Ferrara, capital of an Italian province, stands in the marshy delta of the Po, 30 miles from the Adriatic, and 29 NE. of Bologna by rail. A walled city since 604, it is still fortified with walls, bastions, ditches, and a citadel. The old castle or ducal palace of the Estes, built in the Gothic style in the 14th and 15th centuries, with corner towers, moats, and heavy machicolations, is the most conspicuous secular building in Ferrara. After the extinction of the Este family it was until 1860 the residence of the papal legates. The most notable churches are the cathedral and those of San Francesco, San Benedetto, and Santa Maria in Vado, which contain paintings by native artists (Garofalo, Dosso Dossi, &c.) and others (Guercino, Seb. Filippi). The university, founded in 1264, reorganised in 1402, closed in 1794, and reopened in 1824, has three faculties (medicine, jurisprudence, mathematics), many professors, but very few students. Its excellent library (100,000 vols., rare incunabula, and 1000 MSS.) contains original works of Tasso, Ariosto, and Guarini. Ferrara is specially remarkable for its art associations. Under the patronage of the Dukes of Este it produced a good school of painters; in literature it is closely associated with Tasso, Ariosto, and Guarini. The last named was born at Ferrara, as was Savonarola. At the period of its greatest prosperity Ferrara had about 100,000 inhabitants; though the commune still has 108,000, the town proper has hardly more than 50,000. After passing through various vicissitudes Ferrara became subject to the house of Este about the close of the 12th century, and remained in their hands until the extinction of the family in 1598, when it passed to Pope Clement VIII. In 1860 Ferrara was incorporated in Italy. See books by Gardner (1904) and Miss Noyes (1904).

Ferrara, ANDREA, a broadsword-maker of the 16th century, respecting whose personal history nothing is certainly known beyond the fact that he was established at Belluno in North Italy in 1585, where, along with his brother, he enjoyed great repute as an armourer. According to a tradition long current in Scotland, he was a Spaniard by birth; but the probability that he was an Italian and a native of the city of Ferrara is quite as strong. It is claimed for him that he tempered sword-blades by the same method as that employed by the smiths of Damascus. See *SWORD*; and *Cornhill Magazine*, vol. xii. (1865).

Ferrari, GAUDENZIO, Italian painter, was born at Valduggia, in Piedmont, in 1484. A scholar of

Andrea Scotto, he also caught some inspiration from Da Vinci and Raphael. The chief characteristics of his style are correct and vigorous delineation, strong but often hard colouring, considerable power of invention, and skill in the arrangement of drapery. He executed innumerable paintings both in fresco and in oil, the greater part of which are possessed by the Lombard galleries.

Ferrari, PAOLO, Italian dramatist, was born at Modena in 1822, and produced his first comedy in 1847. Of his many later works, *Goldoni* (1852) and *Parini e la Satira* (1857) rank amongst the finest examples of modern Italian comedy, and are distinguished—as, indeed, are most of his plays—by a piquancy and sparkling dialogue, as well as cleverness of construction and occasional sharp contrasts, such as have been mostly identified with French comedy. He died professor of history at Milan, 10th March 1889.

Ferrates are combinations of ferric acid, HFeO_2 , a weak unstable compound of iron and oxygen, with bases.

Ferrer, FRANCISCO (1864-1909), a theoretical anarchist, distinguished himself by zealous and devoted educational work at Barcelona, especially as founder of 'lay schools,' highly unpopular with clericals and monarchists. He was imprisoned for a year, tried, but acquitted, for alleged complicity in the plot to assassinate the king and his bride (1906). Accused (without evidence) of being instigator of the Barcelona rising of 1909, he was tried by court-martial and summarily shot—a victim of clerical spite, as was believed by many liberals as well as socialists. See book by W. Archer (1911).

Ferrers, LAWRENCE SHIRLEY, EARL, the last nobleman who died a felon's death in England, was born in August 1720, and succeeded to the peerage as fourth earl in 1745. He was subject to ungovernable paroxysms of passion, in the fury of one of which he killed his old land-steward, for which, being tried by his peers in Westminster Hall, he was hanged at Tyburn, 5th May 1760.

Ferret, a half-tamed albino polecat. It is slightly smaller than the wild form, measuring about 14 inches in length without including the tail, and has white or yellowish fur and the usual red—i.e. unpigmented—eyes. Like some other albinos, it is delicate and requires to be carefully housed in cold

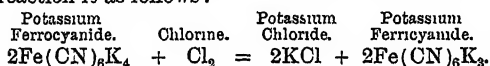

Ferret.

weather. The variety is virtually constant, except when the ferrets breed with polecats, which they will readily do; then a 'variety-hybrid' with intermediate colouring results. The ferret has been for long in human hands, for Aristotle knew it, and the Romans used it as we do. It seems to have originated in Africa, or in southern Europe—e.g. Greece—and may have been reared by the ancient habit of keeping a polecat to hunt for mice, before the days of the domestic cat. In spite of its long training, it is hardly tame, far less affectionate, and needs to be looked after lest it go chicken-hunting on its own account. Even infants are not safe from its deeply ingrained thirst for blood. It is used both in Europe and America to kill rats, to hunt out rabbits, and even to catch

fowls, which it can kill very neatly with a single bite on the neck. Like its relatives, it is brave as well as bloodthirsty, and will attack a large rat without hesitation. In hunting rabbits it is often allowed to work its will in the warren, the terrified inmates being shot or snared as they bolt. Frequently, however, the ferret has a long string attached, so that it may be pulled out. In other cases it is muzzled, and sometimes even belled. Without muzzle or leash there is always a risk of losing the ferret, for if hungry he may gratify his natural inclinations on the first rabbit and fall asleep after his meal, or he may get so excited over his work that he will refuse to come out for days. In time, however, desire for water brings him to the surface again; for blood, as Jefferies remarks, causes great thirst. The ferret generally breeds twice a year, each brood consisting of six or nine, which the mother sometimes devours. See **ERMINE**, **POLECAT**, **WEASEL**.

Ferricyanogen, formerly **FERRIDCYANOGEN**, a compound radical supposed by chemists to exist in ferricyanic acid and the ferricyanides. It cannot exist in the free state. The most important of the ferricyanides is that of potassium, also called red prussiate of potash. It is prepared by passing a stream of chlorine gas into a solution of potassium ferrocyanide till the liquid turns dark-red; on evaporation the salt is obtained in crystals. The reaction is as follows:

The chief use of potassium ferricyanide is for the manufacture of Turnbull's blue, an important dye. This substance is formed when a solution of a ferricyanide is mixed with that of a ferrous salt (green vitriol, for instance); it consists of ferrous ferricyanide, $\text{Fe}_3\text{K}_2(\text{CN})_{12}$. Ferric salts yield no precipitate with ferricyanides. Strong acids separate hydroferricyanic acid, $\text{H}_2\text{Fe}(\text{CN})_6$.

Ferrier, **SIR DAVID** (knighted 1911), physician and scientist, was born at Woodside, Aberdeen, in 1843, and educated at the university there, where he graduated with the highest honours in 1863, and soon after gained the inter-university distinction of a Ferguson scholarship. After a period of study at Heidelberg he settled as a student of medicine at Edinburgh, and graduated in 1868 at the close of an exceptionally distinguished course. In 1872 he was appointed professor of Forensic Medicine at King's College, London, and afterwards became physician to its hospital, and also to the National Hospital for the Paralysed and Epileptic. He was elected Fellow of the Royal Society in 1876, of the Royal College of Physicians the following year, and was made LL.D. by Aberdeen in 1883. Dr Ferrier's chief scientific work has been in the region of the brain, and its relations to such diseases as epilepsy, his name being especially famous for a brilliant series of experimental researches into the localisation of its functions, which have made him a *bête noire* to the anti-vivisectionists. In 1876 he published *The Functions of the Brain*, which was followed by *The Localisation of Cerebral Disease* (1878), and the Croonian lecture (1890) on cerebral localisation; and alone or with others he has written on cognate subjects in the Royal Society's *Transactions* (1884, 1898, &c.). He was one of the founders, and for a time was an editor, of the journal of neurology, *Brain*.

Ferrier, **JAMES FREDERICK**, metaphysician, was born in Edinburgh, June 16, 1808. His father was a brother of Miss Ferrier, the novelist; his mother, a sister of Christopher North. He was educated by Dr Duncan at Ruthwell, at the Edinburgh High School, and at Greenwich by Dr

Burney, next entered the university of Edinburgh, and passed thence to Magdalen College, Oxford, where he graduated B.A. in 1831; next year he was admitted to the Scottish bar, but never practised, while the dominant influence of Sir William Hamilton made him a metaphysician. In 1842 he was elected to the chair of History in the university of Edinburgh, and in 1845 to that of Moral Philosophy in the university of St Andrews. Ferrier early attracted notice by some metaphysical essays, which appeared in *Blackwood's Magazine*; and in 1854 he published the *Institutes of Metaphysics*, in which he endeavours to construct a system of idealism in a series of propositions demonstrated after the manner of Euclid. He afterwards edited the collected works of his uncle and father-in-law, Christopher North. His own *Lectures on Greek Philosophy* were edited in 1866. Ferrier died at St Andrews, June 11, 1864. See *Life* by Miss Elizabeth Haldane (1899).

Ferrier, **SUSAN EDMONSTON**, Scottish novelist, was born in Edinburgh in 1782. Her father, James Ferrier, one of the principal clerks of the Court of Session, and the colleague in that office of Sir Walter Scott, lived on terms of intimacy with the wits and literati of his day in Edinburgh, and Miss Ferrier's talents and quick powers of observation were early called into play in the midst of the literary society in which her youth was passed. Her first work, *Marriage*, begun in 1810 in concert with Miss Clavering, but soon relinquished by the latter, appeared in 1818, and this was followed by *The Inheritance* (1824), and *Destiny* (1831). The merit of these tales, which are characterised by genial wit, a quick sense of the ludicrous, and considerable ability in the delineation of national peculiarities, is sufficiently proved by the fact that by some Scott was credited with the authorship. Miss Ferrier enjoyed the esteem and friendship of Sir Walter, who repeatedly gave expression to his appreciation of her talents, praised her portraits of society, and called her his 'sister-shadow,' and derived consolation from her sympathy in the season of gloom which darkened the close of his life. She figures in Lockhart's *Life of Scott*, and amongst her papers was found an article, 'Recollections of Visits to Ashiestiel and Abbotsford,' published, along with a Memoir and her works (6 vols. 1881). She died at Edinburgh, Nov. 5, 1854. See *Life* by her grand-nephew (1899).

Ferro, or **HIBERO**, the most western of the Canary Islands (q.v.). This island was selected as a first meridian by a scientific congress called together at Paris by Richelieu in 1630. The meridian chosen, 20° W. of Paris, and 17° 39' W. of Greenwich, is not, however, that of the west coast of Ferro, which really lies 20° 1' 45" W. of Paris. Nevertheless it was universally agreed to regard it as lying exactly on the 20th meridian W. of Paris. This first meridian was long used by some European nations. See **LATITUDE** AND **LONGITUDE**.

Ferrocyanogen, a compound radical supposed by chemists to exist in ferrocyanic acid and the ferrocyanides. It cannot exist in the free state. The most important of the ferrocyanides is the potassium salt; it is prepared in the following manner. A mixture of potassium carbonate, iron filings, and animal matter, such as dried blood, horn clippings, &c., is heated to redness in iron pots. Potassium cyanide is thus formed. The mass is extracted with water, the cyanide combines with iron, forming ferrocyanide, which dissolves, and may be purified by recrystallisation. The chief use of potassium ferrocyanide is for the preparation of Prussian blue—ferric ferrocyanide (see **DYEING** AND **CALICO-PRINTING**)—which is formed on the

addition of a ferric salt to solution of the ferrocyanide. A ferrous salt produces a white or light-blue precipitate of ferrous ferrocyanide. By the action of dilute sulphuric acid on potassium ferrocyanide, prussic acid is produced; if strong sulphuric acid be used, the ferrocyanide is completely decomposed, yielding carbonic oxide gas, and sulphates of iron, potassium, and ammonium. Hydrochloric acid causes the separation of ferrocyanic acid, $H_2Fe(CN)_6$, in small white crystals insoluble in hydrochloric acid. Most of the metallic ferrocyanides are insoluble, and many have characteristic colours. Iron cannot be detected in either ferro- or ferricyanides by any of the common reactions. Potassium ferrocyanide is not poisonous. The chemistry of these compounds is not yet thoroughly understood.

Ferrol, a Spanish seaport in Galicia, stands on a narrow arm of the sea, 11 miles by water and 33 by rail NE. of Corunna. A poor fishing-town until 1752, it now is one of the strongest fortified places in the kingdom, and possesses one of its three largest arsenals (with dockyards, naval workshops, &c.), but the annual trade has decayed somewhat. The harbour is safe and capacious, and has a very narrow entrance, defended by two forts. The town has manufactures of naval stores, linen, cotton, and leather, and exports corn, brandy, vinegar, and fish. The 30,000 inhabitants are engaged principally in the arsenal and in the sardine fishery. In 1805 a French fleet was defeated by the English off Ferrol. The town was taken by the French in 1809 and 1823, and in 1872 was the scene of a republican rising.

Ferrottype, or **ENERGIATYPE**, a photographic process, first made public by Robert Hunt in 1844, in which the negative was developed by a saturated solution of protosulphate of iron, with mucilage of gum-arabic, and fixed by soaking in water to which a small quantity of ammonia or hyposulphite of soda had been added.

Ferry, a passage by boat across water. Common rowing-boats are generally used for ferrying foot-passengers, but when horses and carriages have to be taken across, a flat-bottomed barge, with an inclined plane at one end, to rest upon the shore, for landing and embarking, is generally used. This may also be rowed across, but is usually drawn by a cable. The rope stretched across the river passes through rings or over pulleys attached to the barge, and the ferryman move the barge across by pulling the rope. The rope restrains the barge from drifting in the direction of the stream. With a small boat this difficulty is obviated by the ferryman rowing obliquely, as though he were steering for a point higher up the river. Rafts are sometimes used for ferrying; and steam ferry-boats of various kinds and sizes are familiar to everybody.

Flying-bridge is the name given to a kind of ferry-boat which is moved across a river by the action of the combined forces of the stream, and the resistance of a long rope or chain made fast to a fixed buoy in the middle of the river. The boat thus attached is made to take an oblique position by means of the rudder; the stream then acting against the side tends to move it in a direction at right angles to its length, while the rope exerts a force in the direction towards the buoy. The course of the boat is analogous to the path of a rising kite. The holder of the kite corresponds to the buoy, the wind to the tidal stream, and the tail to the rudder. Flying-bridges may be used for military purposes. In the case of a wide river the rope or chain requires to be of considerable length, and must be supported by movable buoys or by small boats. Such flying-bridges are familiar to

those who have sailed up the Rhine. In some cases, instead of an anchor laid in the stream, two shears or masts are erected, one on each bank, and firmly secured by guys. A stout hawser is then stretched tight from the top of one mast to the top of the other. There is a large iron ring or 'grummet,' to which is fastened one end of the boat rope, the other end being made fast to the boat or boats of which the bridge is composed.

Ferry, **JULES FRANÇOIS CAMILLE**, French statesman, born at Saint Dié in the Vosges, April 5, 1832, was admitted to the Paris bar in 1854, and speedily identified himself with the opponents of the Empire. His hostility was carried into journalism, and a series of articles in the *Temps*, in which he analysed the accounts of the prefect who was then rebuilding Paris, were republished as the *Comptes Fantastiques d'Haussmann* (1865). In 1869 he was elected to the Corps Législatif, where he voted against the war with Prussia; and during the siege of Paris by the Germans (1870-71) he played a prominent part as central mayor of the city. He was minister to Athens in 1872-73, and in 1879 became minister of Public Instruction, in which capacity he brought forward an education bill containing a clause, which was levelled at the Jesuits, shutting out members of 'unauthorised religious communities' from the schools. The clause was twice thrown out in the senate, but the expulsion of the Jesuits was effected by decrees founded on laws long since fallen into disuse, and brought about the dissolution of the ministry in September 1880. M. Ferry then formed a cabinet, which remained in office until November 1881. Again becoming premier in February 1883, he boldly embarked on a policy of 'colonial expansion,' involving a war in Madagascar, and an invasion of Tronquin, where a military disaster brought about his downfall in March 1885. He died 17th March 1893. See A. N. Rambaud, *Jules Ferry* (1905).

Fertilisation is that essential process of sexual reproduction in which the male element (spermatozoid, antherozoid, pollen-tube) comes into contact and more or less complete union with the female element or ovum (see **REPRODUCTION**), and through which the subsequent division and differentiation of the ovum becomes effectively possible (see **EMBRYOLOGY**). The term is, however, often more loosely employed to denote those preliminary processes by which the male fertilising element is brought into conditions for beginning fertilisation proper. Hence, while the zoologist speaks commonly of the fertilisation of the ovum, but of the fecundation of the female animal, the botanist, in speaking of the fertilisation of the flower, is referring to the wind or insect agencies by which the pollen is brought to the stigma, and of the details of floral structure and mechanism adapted to these, the term fecundation thus being more frequently applied to the subsequent and essential process. See **FLOWERS**.

Fesa, or **FASA**, a town of Persia, in the province of Fars, about 80 miles SE. of Shiraz, with a population of 10,000. It has manufactures of silken fabrics, and some trade in tobacco.

Fescennine Verses, one of the oldest forms of popular poetry in Italy, consisted of dialogues in rude extempore verses, generally in Saturnian measure, in which the parties rallied and ridiculed one another. The making of them formed a favourite amusement of the country-people on festive occasions, especially at the conclusion of harvest and at weddings. But, degenerating into extreme license, the practice had at last to be regulated by law. The Fescennine verses are usually considered to derive their name from the Etrurian town Fescennium.

Fesch, JOSEPH, Cardinal and Archbishop of Lyons, was born 3d January 1763, at Ajaccio. Of Swiss parentage, he was the half-brother of Letizia Ramolino, the mother of Napoleon Bonaparte. During the French Revolution he became commissary to the Army of the Alps under his nephew in Italy. The First Consul having resolved on the restoration of the Catholic worship, Fesch resumed the clerical habit—for he had originally taken holy orders—and was active in bringing about the concordat with Pope Pius VII. in 1801. He was now (1802) raised to be Archbishop of Lyons, and in the following year to be cardinal. In 1804 he was sent as French ambassador to Rome, where he ingratiated himself with the pope by his adroit management and ultramontane sentiments. Two years later he was appointed associate and successor of Dalberg, Prince Primate of the Confederation of the Rhine. At a national conference of clergy assembled at Paris in 1810 he gave utterance to views which lost him the favour of Napoleon, who was still further exasperated against him on account of a letter which Fesch wrote to the pope, then (1812) in captivity at Fontainebleau, and which was intercepted. After this he lived in a sort of banishment at Lyons. At the approach of the Austrians in 1814 he fled to Rome, where he spent nearly the whole of the rest of his life. His resistance to the will of his nephew, and indeed his whole conduct, seems to have been actuated by sincere zeal for what he considered to be the interests of the church. He died at Rome, 13th May 1839. Of his large collection of paintings he bequeathed a part to the city of Lyons. See *Life* by Ricard (Paris, 1893).

Fescue (*Festuca*), a large and widely diffused genus of grasses, very nearly allied to Brome-grass (q.v.), and including many of the most valuable pasture and fodder grasses—e.g. Meadow Fescue (*F. elatior*, var. *pratensis*), with the allied Tall Fescue (var. *arundinacea*), Sheep's Fescue (*F. ovina*), of which as many as eight varieties are enumerated, but of which, besides the common form, (var. *vulgaris*) only Hard Fescue (var. *duriuscula*) is of agricultural importance. Red Fescue (*F. rubra*) has also the important varieties, creeping (var. *genuina*), tufted (var. *fallax*), various-leaved (var. *heterophylla*), and violet (var. *violacea*). See GRASSES, and PASTURE.

Fess, one of the heraldic ordinaries. See HERALDRY.

Fessa. See FESA.

Festiniog, a village of Merionethshire, North Wales, 22 miles by rail WNW. of Bala, and 3½ S. of Blaenau-Festiniog. Standing amid waterfalls and mountains (the loftiest Moelwyn, 2529 feet), it is a great tourist centre. Pop. 8000. Blaenau-Festiniog, 27 miles SSW. of Llandudno Junction, and 13 NE. of Port Madoc by the 'Toy Railway' (1869), is a place of recent growth, inhabited chiefly by slate-quarrymen.

Festivals, or FEASTS, a term denoting certain periodically recurring days and seasons set aside by a community for rest from the ordinary labour of life, and more or less hallowed by religious solemnities. These may be joyful occasions commemorating the lives of heroes, or general days of humiliation for disasters. But even when sorrow was to be expressed the mortification of the body did not always suffice, but plays, songs, dances, and processions full of boisterous mirth were resorted to—as in the festivals of Isis at Busiris, of Mars at Papremis, in the Adonia of Egypt, Phœnicia, and Greece—because the divine wrath or sorrow was, like that of man, to be changed into satisfaction. Festivals have also helped onward the progress of

civilisation itself. Besides helping to knit together into unity the body politic, they stimulated the artistic sense to emulation in music and the dramatic art, and thus laid the foundations of the greatest æsthetic triumphs. Enthusiastic, wild, metaphysical Egypt invested the countless days consecrated to her deified stars, plants, animals, and ideas, to the Nile, to Ammon, Kneph, Menes, Osiris, to Horus, to Neitha, to Ptah, with a mystery, sensuality, and mournfulness always exaggerated, sometimes monstrous. The Hindu, no longer daring to offer human sacrifices, shows his odd and cruel materialism by throwing into the waves, on his festival of rivers, some of his costliest goods, gold, jewels, garments, and instruments; while in the licentiousness and debaucheries perpetrated on the festival of Siva, the god of procreation, or on the Bacchantics of the goddess Bhavani, he exceeds even those of the Egyptians on their Neitha feasts at Bubastis, and the Greek worship of Aphrodite in her Cyprian groves.

The ancient Persians alone of all nations had no festivals, as they had no temples and no common worship. These 'Puritans of Polytheism,' who worshipped the sun only, and his representative on earth, fire, scorned show and pomp and large religious gatherings. A striking contrast to them is formed, in another hemisphere, by the ancient Mexicans, who were found to possess one of the most richly developed calendars of festivals, scientifically divided into movable and immovable feasts. As a strange and singular phenomenon among festivals we may also mention here that 'of the Dead' or 'of Souls,' celebrated among the wild tribes of North America. At a certain time all the graves are emptied, and the remains of the bodies buried since the last festival are taken out by the relatives, and thrown together into a large common mound, amid great rejoicings and solemnities, to which all the neighbouring tribes are invited.

Greece had received the types of civilisation, religion, and art from Egypt and the East, but she developed them all in a manner befitting her glorious clime and the joyous genius of her sons. At the time of the *Iliad* two principal festivals only—the harvest and the vintage—seem to have been celebrated (ix. 250); but they soon increased to a very large number. The religious part of the festival—homage offered to personified ideas—consisted mostly in the carrying about of the deity of the day to the sound of flute, lyre, and hymns, and in a sacrifice, followed by a general meal upon certain portions of the animal offered. Then followed scenic representations symbolising the deeds of the gods; after which came games and matches of all kinds—foot, horse, and chariot races, leaping, boxing, throwing, and wrestling. Separate accounts are given of some of the more remarkable Greek festivals under BACCHUS, MYSTERIES, and PANATHENÆA, and of the 'Holy Games' proper, the Olympian, the Pythian, the Nemean, and the Isthmian, under these heads. As all these festivities were provided out of the public purse the individual did not suffer more than a welcome interruption of his usual business, and under that genial sky the penalty to be paid for occasional indolence was not too heavy.

Rome adopted and acclimatised the foreign deities as she went on from conquest to conquest, exactly as, with her usual prudence and practical sense, she conferred her right of citizenship on the nations subjected to her rule. Her yoke was thus less galling to the new provinces, while at the same time the populace at home found sufficient distraction in the many ancient and newly imported festivals, with their quaint rites and gorgeous pageantry. Yet the Romans never exceeded in their festivals a hundred in a year, and in these, again, a

distinct line was drawn between civil and religious ones. Some of the principal religious festivals were the *Sementine*, on the 25th of January—the rural festival of the seed-time; the *Lupercalia*, in honour of Pan; the *Cerealia*; the night festival of the Bona Dea; the *Matronalia*; and the *Minervalia*. To the purely civil ones belong the *Januaria*, the 1st of January and the New-year's Day, when the new consuls entered upon their office, and friends used to send presents (*strenæ*) to each other; the *Quirinalia*, in memory of Romulus, deified under the name of Quirinus; and the *Saturnalia*, in remembrance of the golden age of Saturn, beginning on the 19th of December. The celebration of these festivals was in all respects imitated from the Greeks, with this difference only, that the games connected with them became with the pre-eminently bellicose Romans terribly lifelike images of war. Their sea-fights; their pitched battles between horse and foot, between wild beasts and men; their so-called Trojan games, executed by the flower of the nobility; their boxing-matches (with gloves that had lead and iron sewed into them); circus, arena, and amphitheatre, gave, especially in later times, the greater satisfaction the greater the number of victims.

With the first and strictest monotheists, the Hebrews, the remembrance of their liberation from Egypt, and the momentous period of preparation in the desert which followed it, mingled with almost all their religious observances, and especially their festivals, and infused into them all a tone of deep and fervent gratitude; while at the same time it held ever before their eyes the cause of their nationality, and their aim and destiny 'to be a kingdom of priests and a holy people.' The Hebrew festivals, too, are of an historical, agricultural, astronomical, and political nature; but they mostly combine all these characteristics, and are always hallowed by the same religious idea. Connected with their festivals were no plays and no representations of a god's deeds, no games and no cruelty, no mystery and no sensuality, but the sacrifice of the day, and a special occupation with the divine law. The influence of the number Seven (q.v.) is seen in the recurrence of many of the Jewish solemnities. The Sabbath, the first and most important of these septenary festivals, is treated of under its own head. The most exalted of new-moon festivals was that of the first day of the seventh month, 'the day of remembrance of the sounding' or 'of trumpets' (Lev. xxiii. 24), to which in later times, when the Seleucidian era was introduced, the name of *Rosh hashana* (New Year) was given; notwithstanding that in Exodus (xii. 2) Nisan is spoken of as the first month of the year. After a period of six years of labour the earth, too, was to celebrate a Sabbath-year; what it produced spontaneously belonged to the poor, the stranger, and to animals. After a revolution of seven times seven years the year of Jubilee or Yobel was to be celebrated, in which all the Hebrew slaves were set free, and all land which had been sold in the interval was restored to the former owners, in order that the original equilibrium in the families and tribes should be maintained intact. The pre-eminently agronomical and historical festivals were the three *Chaggim*—viz. Pesach (Passover, q.v.), Schabuoth (Feast of Weeks), and Succoth (Feast of Tabernacles), on which three every male was obliged to go up to Jerusalem and offer some of the first fruits, besides the prescribed sacrifices. Post-Mosaic and exclusively historical were the feasts of Purim, of Haman, and of the Maccabees.

Only a cursory glance can be here taken of the Christian festivals, which are treated separately under their various names. They were for the

most part grafted, in the course of time, upon the Jewish and Pagan ones, but always with a distinct reference to Christ and other holy personages. The weekly day of rest was transferred from Saturday to Sunday, and called the Day of Joy or Resurrection. For a long time both Saturday and Sunday were celebrated, especially in the East. Two separate celebrations took the place of the Jewish Passover: the *Pascha Staurosimon* was the festival of the Death, the *Pascha Anastasimon* of the Resurrection of our Lord (see EASTER); and the festival of Pentecost, or the law-giving at Sinai, became the festival of the outpouring of the Holy Ghost and of the inauguration of the New Covenant.

In the course of the 4th century two new festivals were introduced: Epiphany (q.v.), which originated in the East; and that of the Nativity or Christmas (q.v.). Circumcision, Corpus Christi, the festivals of the Cross, of the Transfiguration, of the Trinity, and many others are of still later date. The veneration felt for Mary as the 'Mother of God' found its expression likewise in the consecration of many days to her special service and worship; such as that of her Presentation, Annunciation (Lady Day), Assumption, Visitation, Immaculate Conception (q.v.), and many minor festivals, over and above the month of May and the Saturdays, which in some parts were entirely dedicated to her, in order that the Mother might have her weekly day like the Son. Besides these, there were festivals of Angels, of Apostles, Saints, Martyrs (on the supposed anniversary of their death, called their birthday, *dies natalis*), of Souls, Ordinations, &c. Some were of special importance owing to special circumstances; thus St Patrick's Day (March 17th) is especially sacred to Irishmen, St Andrew's Day (November 30th) to Scotsmen, and St George's Day (April 23d) to Englishmen. In the United States we find corresponding festivals in Washington's Birthday (February 22d), Independence Day (July 4th), Decoration Day (q.v.; observed in 1889 as a legal holiday in twenty-two states), and Thanksgiving Day (usually the last Thursday of November).

Celebrated at first with all the primitive simplicity of genuine piety, most of the church's festivals were ere long invested with such pomp and splendour that they surpassed those of the ancient Greeks and Romans. Burlesque, even coarse and profane representations, processions, mysteries, and night-services were in some places, although unauthorized by the general church, connected with them, and voices within the church loudly denounced these 'pagan practices.' Ordinances forbidding mundane music and female singers for divine service were issued, the vigils were transformed into fasts, days of abstinence and penance were instituted, partly as counterpoises, but with little result. Nor did the prodigious increase of these festive occasions, and the rigour with which abstinence from labour was enforced in most cases, fail to produce the natural results of infolence and licentiousness among the large mass of the people. But it was only after the most decided and threatening demands, as by the German Diet of Nuremberg in 1522, that Pope Urban VIII. was prevailed upon to reduce the number for Catholic Christianity (1642). Benedict XIV. (1742) and Clement XIV. (1773) followed in the same direction.

The Christian festivals have been divided variously into *feriæ statutæ* (returning annually at fixed times), *indictæ* (extraordinary, specially proclaimed), *duplicitæ* (double reminiscence, or of higher importance), *semiduplicitæ* (half double), &c. It was long the custom to recite the office of the Feria in addition to that of any feast chancing to fall on it. Hence, on the more important

solemnities, a *double* office had to be recited, one of the *feria*, another of the feast. *Semi-doubles* were those in which the two offices were made into one. The church celebrates certain festivals till the *octave* or eighth day after they fall due. Another division is into weekly and yearly feasts, these latter being subdivided into greater and minor, or into movable and immovable. There is also a distinction made between *integri* (whole days), *intercisi* (half-days), &c.

The only trace of the ancient manner of dating a festival from the eve or vesper of the previous day—a practice discontinued since the 12th century, when the old Roman way of counting the day from midnight to midnight was reintroduced—survives in the ‘ringing in’ of certain days of special solemnity on the night before, and in the fasts of the vigils.

Some of the principal Mohammedan festivals (see MOHAMMEDANISM) are partly based upon those of the Jews and Christians, such as the weekly Friday (the Jewish Day of Atonement); others are the Birthday of the Prophet, that of Hussein, of Mohammed’s granddaughter Zeynab, of the Night of the Prophet’s Ascension to Heaven, and Bairam (q.v.). See HOLIDAY.

See BREVARY, and works on this subject by Buxtorf, Lightfoot, De Wette, Baumgarten, Mai; also Thomassin, *Traité des Festes*; Gavantus, with Merati’s Notes; and Probst, *Brevier u. Brevier-gebet*.

Festoon, in Architecture, a sculptured wreath of flowers, fruit, leaves, &c., frequently used as an ornament in Roman and Renaissance buildings. Like many of the other ornaments of classic architecture, it owes its origin to one of the sacrificial

Festoon:
St Mark's Library, Venice.

emblems—viz. the flowers with which the heads of the animals, the altars, &c. used to be decorated.

Festus, PORCIUS, Roman procurator of Judæa, who succeeded Felix (q.v.), 60 A.D., and died a few years afterwards. In 62 Paul defended himself before him. See Acts, xxv.

Festus, SEXTUS POMPEIUS, a Latin grammarian, who flourished most probably in the 2d century A.D., and is one of our most important authorities on the Latin language. His epitome of the great work (now lost) of Verrius Flaccus, *De Verborum Significatione*, was arranged alphabetically in twenty books, of which only the latter half (M—V) survives, and even that in a single deplorably mutilated MS. This came from Illyria, and fell into the hands of Pomponius Lætus, a distinguished scholar of the 15th century. It ultimately passed into the library of Cardinal Farnese at Parma, and is now preserved at Naples. The work, in spite of all its imperfections, is a grand storehouse of knowledge on points of mythology, grammar, and antiquities. We have, too, a meagre abstract of Festus’s abstract, compiled by a priest Paulus in Charlemagne’s time. All previous editions of Festus are of little value compared with that of K. O. Müller (1839), in which he has made use of the Farnese MS. and other sources, distinguishing the value of each.

Fetch. See DOUBLE.

Fetichism, the worship of a fetich, or more strictly the belief that the possession of a thing can procure the services of a spirit lodged within it. The fetich is an object capable of being appropriated by an individual, and counted as animate and conscious. We find fetichism flourishing not only in Africa, but among the natives of both Americas, the Polynesians, Australians, and Siberians, and indeed in the lower strata of all known civilisations. The word itself is ultimately due to the Portuguese, the first Europeans to trade on the west coast of Africa, who expressed their conception of the religion of the natives by the Portuguese word *feticção*, ‘magic;’ but it received its currency through the medium of the French, the well-known treatise of Charles de Brosses, *Du Culte des Dieux Fétiches* (Dijon, 1760), having carried the word over Europe. Comte used it as a term to describe what he believed to be a necessary stage in the development of all religions in which all external bodies, natural or artificial, are supposed to be animated by souls essentially analogous to our own. Lord Avebury’s definition of fetichism is closer to its modern scientific sense—‘that stage of religious thought in which man supposes he can force the deities to comply with his desires.’ He makes it the next stage in the ascent of religion from pure atheism through totemism and shamanism into idolatry. But it is impossible to admit this transition from fetichism to idolatry, because the latter necessarily implies the superiority of the god over the man; the former, on the contrary, the superiority of the man over the god. Idolatry is properly the worship paid to an image which is taken to be the usual or merely temporary abode of a superhuman personality. Sir E. Tylor’s definition—‘the doctrine of spirits embodied in, or attached to, or conveying influence through certain material objects’—includes the meaning, but is not expressed with his usual exactness and point.

Fetichism may be said to be *primitive* when man, personifying everything around him, chooses among these imaginary personalities an object capable of being appropriated to himself, the spirit of which becomes his protector or his slave. Again, that may be called *secondary* fetichism which implies belief in the incorporation of a spirit in some object chosen as a fetich, either by a simple act of spontaneous choice or through a magical operation. The latter is far more widespread than the former, and obviously presupposes a belief in animism in Sir E. Tylor’s sense of the word. Any object may become a fetich, provided only it is capable of being appropriated literally or metaphorically by an individual. Such objects are flints, shells, claws, feathers, earth, salt, plants, manufactured articles, anything peculiar or unknown or not understood, trees, streams, rocks, and even certain animals, as the serpents of Whydah. All savage thinking is of course based on fancied analogies, and it is quite enough for an object to be accidentally associated with an event for it to be regarded as the cause and even the author of that event, whence its elevation to the rank of a fetich. Again, fetiches are attached to individuals, to families, or to tribes, and it is even not unusual to see them beaten and kicked as a warning when they have failed to bring the luck that was expected. Even in the crooked sixpences which we carry in our purses, and in the luck-tokens of our gamblers, there is something more than an analogy to the fetich of the savage.

See ANIMISM; Fr. Schultze, *Der Fetichismus* (Leip. 1871); Roskoff, *Das Religionswesen der niedersten Naturvölker* (ib. 1880); Bastian, *Der Fetisch an der Küste*

Guineas (1884); Baudin, *Fétichisme et Féticheurs* (1884); Miss Kingsley's two books on West Africa (1897 and 1899); and Nassau's *Fetichism in West Africa* (1904).

Fétis, FRANÇOIS JOSEPH, Belgian musician, also critic and historian of music, was born at Mons on 25th March 1784. His first appointment was that of organist and professor of music at Douai (1813). He then held successively the post of professor of counterpoint and fugue at the Paris Conservatory (1821), and that of director of the Brussels Conservatory (1833), combining with this last the office of musical director to the king of the Belgians. He died at Brussels, 25th March 1871. He wrote a considerable quantity of music, including operas and sacred music; but he is principally noticed for his works on the theory of music—*Traité de l'Accompagnement de la Partition* (1829), *Treatise on the Theory and Practice of Harmony* (1844), and *Treatise on Counterpoint and Fugue* (1824). But even more valuable than these are his *Universal Biography of Musicians* (1835–44; 2d ed. 1860–65), and *General History of Music* (1869–76). These books, although not free from careless errors, especially in chronology, and although marred by the writer's bias and partiality, are yet of great value to the historian of music.

Fetwa, the decision of a Turkish Mufti given in writing

Feu and Feu-duty, in Scots law. A feu may be described as a right in land, granted in perpetuity—the grantor being called the 'superior,' and the grantee the 'vassal'—in consideration of an annual payment in money, grain, cattle, or services, called *feu-duty*, and certain other contingent burdens called casualties of superiority (see CASUALTIES). Though the term feu was used by feudalists to express any relation of superior and vassal, in Scots law it was opposed to ward or military holding, and to blench or nominal holding. The superior and vassal each continues to have in law an estate, or right of ownership, in the land. But at the present day the vassal holds the land by a permanent and indefeasible tenure, so long as he pays the feu-duty, and the right of the superior is substantially nothing more nor less than the right to draw a fixed sum secured upon the land from the vassal. The system of feuing property for building purposes has several advantages over that of the long building-leases common in England. From its perpetual character it gives to the holder a greater interest in the property, and usually leads him to erect more enduring structures than he would do under a lease. For as time runs on the feu often increases in value, while the reverse must always be the case with the interest of the tenant in leasehold property. Hence the movement for leasehold enfranchisement in England, which is scarcely intelligible in Scotland. Neither does feuing interfere with the letting of property on lease or otherwise. Almost all the houses in Edinburgh and the other towns of Scotland which are let, either on leases or from year to year, are held by their proprietors in feu. Modern feu-duties are in general paid in money. When the stipulation is for a duty in grain the quantity is valued by *fiar* prices (see FIARS), and paid in money accordingly. Since 1874 the feu-duty, whether of money or grain, must be of fixed amount—i.e. not contingent. The original deed transferring the land in feu from the superior to the vassal is called a feu-charter or feu-contract, which is now a very simple and intelligible document. Registration has now the effect of *sasine* in making the vassal's right real; and, unless otherwise stipulated, the vassal is now perfectly free to transfer his property to any one. No charter or other writ of the superior is now necessary to complete the transferee's title.

Usually the feu-charter reserves to the superior all minerals in the ground, and stipulates that the vassal shall build his house either in a particular style or of a certain value. By the Scottish statute 1597, chap. 246, it is declared that all vassals by feu-farm failing to pay their feu-duty for two years together shall lose their right; but the superior is bound to accept payment of arrears before declaring an 'irritancy'—i.e. forfeiture. For the most part, land proprietors near towns and manufacturing villages are anxious to add to their annual rental by feuing grounds for building purposes. The rate of feu varies widely, from as low as £8 to as high as £500 per acre per annum; a common rate is from £20 to £40 per acre. Whatever be the amount, it is payable by the feuar—not the tenant to whom the feuar may have let the property. When a building consists of several floors forming distinct dwellings, the feu-duty payable in respect of the land is allocated by arrangement between the parties in certain proportions among the respective proprietors. When the feu-duty is thus split up each proprietor is responsible only for his own share. In the same way, when a property is sold subject to a *cumulo* feu-duty, it is necessary, with the consent of the superior, to *allocate* this feu-duty on the different portions of the subject. When feu-duties are offered for sale the vassal has an opportunity of extinguishing his feudal tenure, and becoming the superior. It is not unusual in feuing building-lands for the superior to make the roads and drains, the vassals being bound to contribute relatively to the first expense, or at least the subsequent maintenance of both. Interest does not run *ex lege* on arrears of feu-duties till a demand for payment is made.

Feud in the middle ages meant a war waged by private individuals, families, or clans against one another on their own account. See VENDETTA.

Feudalism. The feudal system formed in medieval Europe the connecting link which united the primitive society, whose basis was entirely personal, with the modern reign of law and order. It may be described as a great military and social organisation based on the holding of land, yet containing, imbedded within itself, like fossils in the rocks, the relics of the earlier systems which in each different country had preceded it. The result of the system was the establishment of the various great European powers on the ruins of the Roman empire, and the preservation of order and discipline in the wild times of the disintegration of that empire. For a clear understanding of the feudal system, how it came to be introduced, and the changes it wrought, a glance is necessary at the social systems which preceded it, and which can for this purpose be classed under two leading types, the Teutonic and the Roman, known respectively as the Mark system and Emphyteusis. The industry of Stubbs, Seebohm, and others has thrown a flood of light on the working of the mark system in the primeval German forests, by which we can almost accurately reproduce the primitive society and trace its growth.

In the first century the tribes seem to have been purely nomadic, each kept together under the control of its head, having cattle and other belongings, but no idea of permanent possession of the land, or, indeed, of anything more than taking the pasture and fruits of the earth for the time being, and defending their temporary encampment as long as they remained there. Each chief had his personal following, called by the Romans his *comitatus*, composed principally of the younger

sons of the chief families, and of men who preferred a life of adventure to peaceable cattle-feeding. The chief's council was composed of the heads of the chief families. In many of the larger tribes there were subordinate divisions, presided over by inferior chiefs, but the organisation, whether of the whole or of an individual part, was the same. Probably originally every man was free and equal, but by degrees a class rose up composed partly of prisoners taken in war and kept as slaves, partly of gamblers who, having lost all else, staked their freedom, and lost that; others, again, from mere poverty, might voluntarily surrender their freedom for subsistence, and thus a class of unfree men would gradually spring up. By degrees these nomadic tribes took to settling and cultivating the land, the influence of increasing wealth and civilisation and the knowledge of agriculture, derived from their Roman neighbours, tending largely to promote this result; but still the same broad principles obtained. A group of families would settle on an unoccupied tract of land, and the council of the heads would assign to each family a spot to build a homestead, and to put up cattle-sheds and stackyards; all the rest of the land they occupied in common. A fertile glade was chosen for a common meadow, and to each family the council allotted a share proportionate to its numbers. Each family cut and harvested its own hay, then the fences were thrown down, and the meadow became common pasture till the grass began to grow again next spring. Around the village and the meadow were the woods and wastes, always common, never divided or inclosed; these were called the 'mark,' a word meaning a boundary, and which yet lingers in the Scottish and Welsh Marches, and whence came the name of the Province of Meicia.

The next step in civilisation was the knowledge of tillage, and as arable ground could not well be re-allotted every year, a portion large or small came by degrees to be attached to each homestead, and not included in the yearly subdivision. Still, however, there was no ownership of land as we understand it. The head of each family was a member of the community, a freeman and a political unit, and in that capacity had a homestead assigned to him; this homestead was the outward badge or sign of his status as a freeman. This village was called the mark, a group of marks formed a district, called by Roman writers 'Pagus,' and by English writers a Hundred. The pagus elected a chief, who was a kind of local judge, and each pagus sent representatives to the national assembly, in whom the central power was vested. In war each pagus sent a hundred champions to the host, the nucleus of which was the chief of the tribe with his comitatus. Thus the host was simply the nation in arms, arranged according to the same divisions as in peace; and when a country was conquered they had merely to settle down in the order they stood, and recommence their mark life in a new place. The position of a Teutonic land-owner, then, was that he held his land not of any superior, but in token of his status as a freeman and head of a household; and on his death the assembly of the markmen would confer the homestead on the man on whom that headship devolved, which also, to some extent, they had the power of regulating. Such a system was it that in the 5th century the Saxons, Angles, and Jutes introduced into England; and its traces, notwithstanding the lapse of fourteen centuries, may still be found in village greens and many of the rights of common, whenever the latter are not manorial. Large grants of land were made to distinguished warriors of the comitatus, who settled down with their dependents and slaves, forming villages on their lands in analogy to the mark. The whole country was now

looked upon as one great mark, the unallotted lands forming a sort of treasury out of which grants could be made to new-comers by the great council. Theoretically, the possession of land still was the badge of a freeman; yet, as these grants of land were alienable, and could be sold, a class of landless men gradually arose, and as these had no visible sign of their status it became the rule that every landless man must commend himself to some land-owner who should be responsible to the state for him. Also, the smaller land-owners would often commend themselves to some powerful lord for the sake of honour and protection. A second stage in the progress of social organisation was thus reached; the purely personal basis was no longer the sole foundation of society, the land-owner, not the freeman, became the unit; the host was the body of land-owners in arms; but still it was open to the landless man to select his own lord, and such selection created no indissoluble tie; besides this, the freeman was still in political theory the equal of the noble, and thus the personal basis, though obscured, was not entirely lost sight of.

In the meantime developments somewhat corresponding to these were taking place in the Roman empire; long or perpetual leases of lands taken in war were granted by the state in the tenure called *Emphyteusis*. About the time of Constantine this tenure was also adopted by private persons and corporations, and was extended from land to houses, the person to whom the grant was made being called *Emphyteuta*. It may be defined as a grant of land or houses for ever or for a long period on the condition that an annual sum (*canon*) shall be paid to the owner or his successors, and, if not paid, the grant shall be forfeited. The *emphyteuta* is not legal owner, nor a mere hirer; but the agreement is determined by the *Lex Zenoniana* to rest neither on letting nor on selling, but to be a peculiar contract depending on agreements of its own. The *emphyteuta* had the usufruct of the land, was entitled to its fruits, and under certain restrictions could alienate his possession, which on his death passed to his heirs; but the ownership remained with the *dominus-emphyteuseos* or lord, and the *emphyteuta* was bound to pay the agreed rent, to manage the property as a good paterfamilias, and to pay all the burdens and deliver the receipts to the lord. A good account of this tenure may be found in Hunter's *Roman Law*, pages 426-429. In the later empire, by a modification of this tenure, the frontier lands on the Rhine and Danube were granted to chiefs of the German tribes on condition of their being always ready to defend the integrity of the empire, this service being taken in lieu of the canon or rent of the ordinary *emphyteusis*. Thus the rival systems of the German mark and the Roman *emphyteusis* were brought into direct juxtaposition, and when the barbarians, who for so long had hung 'poised on the edge of the empire,' broke into the Roman world, carrying their ideas of social organisation with them, it was natural that the grants of conquered lands to great warriors should be made on terms analogous to *emphyteusis* rather than (as happened in the earlier conquest of Britain) on the older mark system. These grants were called *beneficia*, the *beneficium* being held on condition of the performance of certain services, of which the most important was naturally military. As in England also, so on the Continent the weaker and poorer would commend themselves to some powerful lord, surrendering their allodial lands (i.e. those held in absolute ownership) to him, to be received back in a sort of *emphyteusis* tenure on condition of the performance of military service. Hence arose feudalism. Littré makes the Low Lat. *feudum* of Teutonic origin, and thus cognate with Old High German *fihu*, Gothic *faihu*,

A.S. *feoh* (our *fee*), mod. Ger. *vieh*, cattle being originally the only wealth. It came subsequently to mean property of any kind, including land, the second part of the root being taken from the word *od*, also meaning property or pay; thus *fee-od*, *feodum*, or *feudum* means property held on condition of pay or services rendered. Guizot in *Civil France*, iv. 41, says: 'The word (feudalism) appeared for the first time in a charter of Charles the Fat in 884.'

So now the third stage of progress was reached, when land became the sole basis of society, the sacramental tie of all public relations; the poor man depended on the rich, not as his chosen patron, but as the owner of the land he cultivated, the lord of the court to which he did suit and service, the leader whom he was bound to follow in the field (see Stubbs, i. 187). The feudal theory was that the king was the sole allodial or absolute owner of all the land in the kingdom; the chief lords held their lands from him on condition of military service; their vassals from them on similar conditions; and sub-vassals from them again, and so on in an infinite chain; each vassal owing fealty to his own immediate lord, but being bound by no tie whatever to the lord's lord. Such was the leading principle of the system which prevailed over France and Germany at the time of the Norman Conquest, which was introduced into England by William the Conqueror and his Normans, and engrafted on the Saxon mark system, but modified by the genius of William I. to suit his own theories of statesmanship. It was introduced about the same period into Scotland by various adventurous Norman knights, and engrafted on the older clan system with such modifications as suited their purpose. Thus three distinct types of feudalism arose with marked differences, as we shall see. The disruptive tendency of the continental feudalism is obvious; the system was there pushed to its logical conclusion. Thus, for instance, the Duke of Brittany was vassal of the king of France, and owed him fealty, as did the vassals of the duke to him, but between the king and the vassals of the duke there was no tie whatever. When therefore the duke chose to throw off his allegiance and rebel against the king, his vassals were bound by their feudal obligations to support him. Such a system could only result in making France a mere congeries of powerful barons bound by slight ties to a nominal head. The weakness of the Carolingian kings and the early Capets largely conduced to this, as did also the degeneracy of the people, who seem to have forgotten that they ever had rights, and who became the ready tools and subservient slaves of the ambitious nobles. In Germany, though the disintegrating tendency was equally marked, the social development was different, owing to the sturdy independence of the German people making it necessary for any chief who aimed at independent power and throwing off the yoke of the central authority to identify himself with the nationality and the aspirations of his vassals. In this way the Guelphs became practically independent lords of the vast fiefs in Swabia, and many another great chief threw off his feudal allegiance, and Germany became a collection of confederacies, the feudal lord of each being representative of the race of his vassals, as well as supreme land-owner.

William I. in introducing feudalism into England had no intention of becoming himself a mere *roi-fainéant*; he intended to be king of all England, lord of the lowest as well as the highest, not mere feudal lord of a number of practically independent chiefs. In this policy of course he had to face the opposition of his chief followers, whose object was to carve out large lordships for themselves, rendering a nominal homage to William, but practically independent of him. William's policy showed a

grasp of the principles of statesmanship rarely equalled; being obliged to reward his chief followers handsomely, he soon saw that it would be dangerous not to make large grants of land, and equally dangerous to make such grants as would enable them to set up independent kingdoms. The plan he took was to make extensive grants, but to scatter them through various counties. For instance, his half-brother Odo of Bayeux got 439 manors, but they were scattered through 17 counties; Robert of Mortain had 793 manors scattered through 20 counties. Thus, had either of these been minded to rebel, no coherence or union was possible among vassals so scattered, and in each county an attempt to collect forces for rebellion would have resulted in a collision with a powerful sheriff at the head of his *fyrð* (the army of the shire), who, being a continuation of the Saxon and popular system of government, and being royal officers entirely, might be trusted to curb the lawless barons. This, however, was not all. No sooner was William I. firmly seated on the throne, and the Domesday survey completed, than in 1086 at Salisbury he took a step which was in direct violation of the elementary feudal principles; for he summoned a great meeting to which we are told there came 'all his witan and all the land-owners of substance in England, whose vassals soever they were, and they all submitted to him and became his men, and swore oaths of allegiance to him that they would be *faithful to him against all others*.' Thus there was provided a direct tie between the king and all the freeholders which no intermediate tie would justify them in breaking.

We may now consider the nature of the services on condition of which land was feudally held, premising that in English nomenclature the man who held land was called a *tenant*, the land holden was his *tenement*, and the conditions of holding his *tenure*. Tenures, then, were of three kinds, answering to the three chief classes of the community, viz. free, unfree or base, and religious; and each of these might be for certain services—i.e. a fixed amount of money or labour at fixed periods—or uncertain—i.e. such amounts and at such times as the lord might require. For example, the free and uncertain tenure, usually considered the noblest of all the tenures, was on condition of following the lord when he went to battle (which might of course be every year, or not at all for a number of years), with a body of men and for a number of days in the year accurately proportioned to the size and value of the holding; this was called Tenure in Chivalry or by Knight Service. The free and certain tenure was the payment of a fixed sum of money, or sometimes the performance of some service of a peaceful and usually agricultural nature, and this was termed Free and Common Socage. The base tenures were those which depended originally on the performance of menial offices, and were in fact the tenures by which serfs allowed to squat on the lords' land held their little patches at the will of the lord; a modernised and greatly modified form of this tenure still exists in England under the name of Copyhold (q.v.). The religious tenures, under which in early times all the church lands were held, were known as Frankalmoin and tenure by Divine Service, the theory being that the prayers of holy men were all they could be called on to give by way of service to men, and the difference between the two being simply that in the former the number and times of the prayers was left to the conscience of the tenant, in the latter a certain number of masses was laid down, and if they were not duly said the lord had his remedy by distress; this last tenure became obsolete at the Reformation. Frankalmoin or free alms is still the tenure whereby in England

the parson holds the church and glebe, the nearest thing to allodial ownership known in England. The necessity, especially in military tenures, of knowing accurately who the tenant was, gave rise to a number of so-called 'incidents of tenure.' Thus, on death of a tenant, the custom of the particular manor, which was pretty much the same all over the country, pointed out who by descent became his rightful successor; if the heir was a minor, another incident gave the lord the wardship of his person and lands till his majority; if a female, the lord might dispose of her hand in marriage, lest she should marry a hereditary enemy; if the tenant wished to sell his land, the lord must accept the new-comer as his tenant; and if the tenant died altogether without heirs, the land escheated to the lord. Accordingly, the lord might always know who his tenant was, and where to look for his services.

In England, though the oath at Salisbury to a large extent took the sting out of feudalism and minimised its disruptive effect, all these results and incidents developed themselves with great luxuriance and symmetry; but in or about the time of Henry II. a custom arose of commuting all the services for money to be spent in pay of mercenary soldiers, and thus another blow was dealt at the personal relationship based on land-holding which was of the essence of the feudal system. Later still, in the reign of Edward I., was passed the famous statute known as *Quia Emptores* (18 Ed. I. chap. 1), prohibiting any vassal from granting any land to be held in fee-simple under himself, and enacting that if he wished to sell it he must do so out and out, so that the purchaser thenceforth should hold of the same chief lord as the seller had held of before. Thus the formation of the infinite chain of lord, vassal, and sub-vassal was checked, till in process of time it has come about that nearly all freeholders in England hold directly from the crown. About the same time in France the influence of powerful kings began to absorb the semi-independent dukes and princes into the crown, but not till the following century was the result finally achieved by Louis XI. He broke the feudal power of the great Duke of Brittany, the last, as he was the most powerful of the feudatories of the crown. In this way French feudalism became a thing of the past by the absorption of all the mesne lords, finally bringing about the same end which William I. accomplished by masterly policy in England; but bringing it about by dint of the sacrifice of all the great nobles, and reducing France to the condition of a powerful king with a weak and servile people, a state of things necessarily leading to the greatest tyranny and to revolution and upheaval. Meantime in England the progress was steady and certain. *Quia Emptores* destroyed the disruptive force of feudalism; but the old military tenures remained in name, though in fact they were little more than excuses whereby the lord contrived to screw money out of the unlucky tenant in the guise of fines for alienation, reliefs on taking up the inheritance by the heir, heriots, first-fruits, prime seisms, &c. There were also the aids given by the tenant at certain expensive epochs of his lord's life, viz. when he was taken prisoner and required ransom, when his eldest son was dubbed a knight, and when his daughter was married—*pur ransommer son corps, pur faire fitz chevalier, et pur marier sa fille*. The extortion to which the feudal system finally degenerated, when all its original purpose was gone, was put an end to by the Statute abolishing Military Tenures, passed on the restoration of Charles II.; and from that time forward feudalism to all intents and purposes was dead in England, save only so far as it affected the forms of conveyance of land. A few

of the old tenures were preserved, probably on account of their picturesqueness and of their being too light to be any real burden, such as the tenures of grand and petit serjeanty, under the latter of which the Dukes of Marlborough and Wellington hold their lands on condition of the presentation of a flag to the sovereign.

We have seen how in France the disruptive nature of the feudal system and its tendency to create a class of petty sovereigns more powerful than their feudal lord proved the destruction of the system itself in that country in the 15th century; and how the very introduction of it into England was marked by a violation of one of its essential features, so that feudalism in its integrity never existed in England. But probably the country where the system can be most advantageously studied in its development and decay is Scotland; into this country it was introduced not by a powerful monarch like William I., but by a number of restless and ambitious Norman knights journeying north in search of adventure, who by their good swords and their Norman talent for organisation made themselves chiefs of powerful clans. The process by which this was accomplished and its general good effect on the country have been well shown by the Duke of Argyll in *Scotland as It Was and as It Is* (2 vols. 1887). From these Norman knights the great houses of Bruce, Stewart, Fraser, Grant, Comyn, and many others take their rise; but the poverty of the country and the sparseness of population, constantly reduced by devastating wars, prevented the aggrandisement of the feudal lords, and checked the disruptive tendency of the system just sufficiently to preserve its vitality to a comparatively modern period. Indeed, in the rebellion of 1745, it became evident that sufficient of the feudal spirit remained to be a source of danger to any government which chanced to be unpopular with the Highland chieftains, and also sufficient of its disruptive and disintegrating tendencies to render any enterprise depending on their support extremely precarious. Accordingly, after the suppression of that rebellion, the military tenures were abolished by legislation very similar to that which at the Restoration had abolished them in England. Nothing analogous to the oath at Salisbury ever took place in Scotland; accordingly the development of the system which made every chieftain a king in miniature, whose little realm was a sort of microcosm of the whole kingdom, proceeded unchecked. No statute analogous to *Quia Emptores* ever prevented subinfeudation, and accordingly to this day there may be any number of links in the chain of superior and vassal and sub-vassal; while in England, since no sub-vassal could be created after 18 Edward I., the intermediate lords have for the most part gradually dropped out, and most land-owners now hold directly from the crown, which was one result aimed at by William I., resulting in the most complete consolidation of the country.

Those who wish to see the remains of the feudal system in visible, albeit dead and fossilised form, may do so more completely on the banks of the Rhine than almost anywhere else. The castle of the feudal baron towers on its height; the village of his dependents nestles at its foot, with the church whose priest was his tenant in frankalmoign, or maybe his chaplain; the pier, it may be, which paid his dues—in fact, all the machinery of a tiny kingdom. Between one baron and another there might be friendship; there was more often feud. Over a number of the barons was some feudal lord, a prince-bishop perhaps, or a duke, and over them again the king; and in legend and story as well as in visible remains of the ancient buildings may be traced all the ramifications of the system, till the

eye of fancy can without much difficulty reconstruct it again.

See the histories of Hallam (1818) and Stubbs (1874-78); works by F. W. Maitland, Vinogradoff, and J. H. Round; Seebohm, *Village Community* (1883); Guizot, *Histoire de la Civilisation en France* (1845); Waitz, *Deutsche Verfassungsgeschichte* (new ed. 1879-86).

Feu de Joie, or 'running-fire,' a discharge of musketry into the air, by a line of soldiers, in honour of a victory or other great occasion. It commences with the right-hand man of the line, and passes rapidly down it, each man discharging his rifle after a short but regular interval, till the extreme left of the line is reached.

Feuerbach, LUDWIG ANDREAS, German philosopher, fourth son of the following, was born at Landshut, 28th July 1804. After he had studied theology for two years at Heidelberg under Paulus and Daub, Hegel attracted him to Berlin, and ere long he abandoned theology for philosophy. In 1828 he became *privatdocent* at Erlangen, but failed as a lecturer, and next retired to Bruckberg, where his wife's means enabled him to live in studious quiet for more than twenty years. In 1830 he published anonymously his *Gedanken über Tod und Unsterblichkeit*—an attack on the doctrine of immortality—and during the next few years, works on the philosophers between Bacon and Spinoza, on Leibnitz, and Pierre Bayle. But these historical works only paved the way to a critical investigation into the nature of religion and its relation to philosophy, the results of which have been given to the world in several works well known to speculative theologians. The most celebrated of these is his famous work on the nature of Christianity, *Das Wesen des Christenthums* (1841), which had the honour of translation into English from the pen of Marian Evans (George Eliot). Starting from the Hegelian doctrine that the Absolute comes to consciousness only in humanity, Feuerbach denies to it any existence beyond the human consciousness, maintaining it to be merely the projection by man of his own ideal into the objective world, on which he feels his dependence. All authority above man, and consequently all moral obligation, is therefore consistently regarded as a delusion proceeding from man himself, and the highest good is explained as that which is on the whole most pleasurable. Yet even this highest good is further explained as consisting in resemblance to that ideal humanity which man creates for himself, and worships as God. A kind of ideal theism is therefore retained by Feuerbach; but when his doctrines were adopted by the mass of German communists, they degenerated, perhaps logically, into an actual atheism, which ignored any moral or social law imposed on the individual from any other source than himself. The last years of the philosopher were vexed with poverty, from which he was relieved by the offerings of admirers, by paralysis, and at last by death, 13th September 1872. His works were collected, with additions and corrections to bring them into accordance with his later views, in 1846-66. See books by Grün (1874), Beyer (1872), Starcke (1885), Engels (1888), Bolin (1891), and Lévy (1904).

Feuerbach, PAUL JOHANN ANSELM VON, one of the most distinguished criminal jurists of Germany, was born at Jena, 14th November 1775. From the gymnasium at Frankfurt-on-Main, where his father was an advocate, he passed in 1792 to Jena to study first philosophy, then law. Already he had made a brilliant reputation by his *Kritik des natürlichen Rechts* (1796), and his *Anti-Hobbes* (1798), when he began to deliver lectures which introduced into criminal jurisprudence a new method of treatment, systematised in his *Lehr-*

buch des gemeinen peinlichen Rechts (1801; 14th ed. 1847). This celebrated work placed Feuerbach at the head of a new school of jurists, who maintain that the decision of the judge in every case ought to be determined solely by an express deliverance of the penal law, never by his own discretion, and who on that account obtained the name of Rigorists. It gave a powerful impetus to the feeling in favour of more humane and less vindictive punishments. In 1801 he was appointed professor in Jena, but in 1802 accepted a call to Kiel. In 1804 he removed to Landshut; but next year he was transferred to an official post in Munich, and in 1808 was appointed privy-councillor. The new penal code which he planned for Bavaria (1813) was taken as a basis in the emendation of the criminal law of several other countries. During this period also he published his *Merkwürdige Kriminalrechtsfälle* (1808-11). In his *Geschworenengericht* (1813) he maintained that the verdict of a jury is not necessarily adequate legal proof of a crime. Supplements were published in 1819 and 1821, and a second volume was added in 1825. In 1814 Feuerbach became second president of the Court of Appeal in Bamberg, and afterwards first president of the Court of Appeal at Anspach. In 1832 he published a work on Kaspar Hauser (q.v.). He had just edited a collection of his *Kleine Schriften* when he died suddenly at Frankfurt-on-Main, 25th May 1833. An interesting life was written by his son Ludwig (2 vols. 1852).

Feuillants, CONGREGATION OF, a reform of the Cistercian order, remarkable as forming part of the great religious movement in the Roman Catholic Church during the 16th century, contemporary with and probably stimulated by the progress of the Reformation. The author of this reform was Jean de la Barrière, abbot of the Cistercian monastery at Feuillants in Languedoc (20 miles south-west of Toulouse), who, painfully struck by the relaxation of its discipline, laid down for himself a new and much more austere course of life, in which he soon found many imitators and associates among the brethren of his order. The rule thus reformed was, after considerable opposition from the advocates of the old rule, approved, with certain modifications, by Pope Sixtus V., the reformed congregation, however, being still left subject to the authority of the abbot of Cîteaux; and a convent was founded for them by Henry III. in the Rue St Honoré, Paris. The subjection to the abbot of Cîteaux was removed by Pope Clement VIII. in 1595; and Urban VIII. in 1630 separated the congregation into two branches, one for France and the other for Italy, each under a distinct general. The rules of both these branches were subsequently modified about the middle of the same century.

The celebrated revolutionary club of the Feuillants took its name from this order, whose convent in the Rue St Honoré was its meeting-place. It was founded in 1790 by Lafayette, Sieyès, Laroche-foucauld, and others holding moderate opinions, but it soon fell before the devouring fire of revolution. At length, on the 28th March 1791, the assembly in the cloister was forcibly dispersed by a raging mob. In October 1791 the extreme right and the right in the Legislative Assembly were often called Feuillants.

Feuillet, OCTAVE, a distinguished French novelist, born at Saint-Lô, in La Manche, 11th August 1821. He was numbered for some time in the band of Dumas' literary assistants, and began his own literary career with *Le Fruit défendu*, in the *Revue Nouvelle*. From 1848 he published in the *Revue des Deux Mondes* a series of

proverbs, comedies, tales, and romances, collected in *Scènes et Proverbes* and *Scènes et Comédies* (5 vols. 1853-56). Elected Scribe's successor in the French Academy (1862), and afterwards librarian to the emperor, he died 29th December 1890. Some of the earlier novels, as the pathetic story *La Petite Comtesse*, gave promise of power, but his popularity as a novelist really awoke with the publication of the masterpiece *Le Roman d'un Jeune Homme Pauvre* (1858), and the only less beautiful *Sibylle* (1862). These were followed by *M. de Camors* (1867), *Julia de Trécœur* (1872), *Un Mariage dans le Monde* (1875), *Les Amours de Philippe* (1877), *Le Journal d'une Femme* (1878), *Histoire d'une Parisienne* (1881), and the striking *La Morte* (1886). He wrote many successful comedies, but it remains true that his dramatic faculty is more effectively displayed in his novels than in his work for the stage. Feuillet had many excellent gifts as a writer of fiction. His stories are cleverly constructed, gracefully told, and unstained by coarseness; he is thoroughly acquainted with the high circles in which his characters move; he has pathos and even passion at his command. Yet he cannot be classed as a great novelist. He never created a really strong character; he frequently strikes a false note; he indulges in morbid sentimentalism, and has a weakness for treating dubious situations while posing as a strict moral teacher. These defects are in the main unapparent in *Le Roman d'un Jeune Homme Pauvre*, but the story, though interesting and in parts charming, yet fails to leave a powerful impression on the reader.

Feuilleton (Fr. lit. 'a small leaf'), the name applied to that portion of a political newspaper set apart for intelligence of a non-political character, for criticisms on art or literature, or for fiction, and usually separated from the main sheet by a line. The feuilleton was first adopted in 1800 by the Abbé Geoffroy for dramatic criticisms in the *Journal des Débats*, but by degrees the element of belles-lettres became dominant, and the result was a species of light journalistic literature, in which Jules Janin became the acknowledged king. In the years immediately preceding the revolution of February 1848 entire romances were spun out in the feuilleton, as the novels of Eugène Sue in the *Constitutionnel*. Among the later French *feuilletonistes* may be named Fr. Sarcey, P. de Saint-Victor, Alb. Wolff, Jul. Claretie, and A. Scholl. The French system has been imitated in Germany, though with less success than in France, but has hitherto found less favour in England. The more eminent of recent German *feuilletonistes* are K. Frenzel, P. Lindau, L. Pietsch, F. Gross, O. Bauck, and the humorists, Eckstein, Stettenheim, Trojan, and Dohm.

Féval, PAUL HENRI CORENTIN, a French novelist, born at Rennes, September 27, 1817. Of his many bright and vigorous novels may be named *Les Mystères de Londres* (1844), *Le Fils du Diable* (1847), and *Le Bossu* (1858), the last named dramatised with much success. Féval became converted to the strictest Roman Catholicism in 1876. He died at Paris, 8th March 1887.

Fever (Lat. *febris*) is a condition of the system in which the most marked sign is rise in temperature. It is one of the most common accompaniments of disease, especially of disease caused by infection. When it occurs in a moderate degree, it must be regarded in general as a necessary accompaniment to the processes which form the defensive mechanism of the body against bacteria and other outside influences which produce disease. In some persons a feverish condition is provoked by very slight causes, as in children and in hysterical subjects.

The temperature of the body is regulated by a nervous and chemical mechanism, so that in health it ranges between 98.4° and 99.5° Fahr., liable to slight variations from the eating of food, muscular exertion, and a natural fluctuation which rises about four in the afternoon and sinks to its lowest point in the early morning. The maintenance of the proper amount of heat when the surrounding air becomes colder is brought about by contraction of the vessels in the skin, and a destructive oxidation of the bodily tissues. In the feverish state the latter process takes place to an excessive degree, and the skin, which at first is cold and bloodless, becomes later flushed in an attempt to get rid, from the surface, of the unusual amount of heat produced in the deeper tissues. In this condition the body wastes rapidly, the loss to the system being chiefly in the form of nitrogen compounds; so that in the early stages of a fever a patient excretes about three times the amount of urea that he would excrete on the same diet if he were in a state of health. The degree of the fever is estimated by the height of the temperature above the normal standard. In most of the febrile diseases, like influenza, rheumatic fever, diphtheria, &c., a rise to 102° or 103° is usual; in others, the oxidation process in the tissues is more violent, and in pneumonia, typhoid fever, &c., it frequently stands at 104° or 105°; when it reaches as high a point as 106°, the term 'hyperpyrexia' (excessive fever) is applied, and this is regarded as a point of danger; while if it exceeds 107° or 108° Fahr. for more than a short period death almost always results. Sometimes in febrile diseases, in apoplexy, &c., the temperature may rise to 110° or more before death takes place.

The commencement of a fever is usually marked by a 'rigor' or shivering, which may only exist as a slight but persistent feeling of chilliness, or may form a distinct stage of the attack, as in malaria, or may even be so violent, as sometimes happens with children, that well-marked convulsions appear. There are other feelings of illness also, such as pain in the back, headache, sickness, thirst, and great lassitude. This stage, known as the 'chill' or 'cold stage,' is soon followed by the full development of the 'hot stage.' The skin now feels hot and dry, and the temperature, raised above the normal level, is often found to show daily variations corresponding to those of health—that is, a rise in the evening, with a fall towards normal or even sometimes below normal every morning. There is an increase in the rate of the pulse and of the breathing; the tongue is dry and furred, especially in some fevers, like typhoid; thirst is marked, the appetite disappears; while the urine is scanty, and of high colour. The bowels are generally constipated, though in some fevers, like dysentery and typhoid, in which the intestine is diseased, there is diarrhoea. The nervous system shares in the general disturbance, so that sleeplessness and often delirium come on. The wasting of the muscles is very marked after some days of fever, and there is consequently great loss of strength, even although considerable quantities of food are taken. Some fevers come to a sudden end by *crisis*, when the temperature falls to normal along with profuse perspiration, copious flow of urine, and disappearance of the nervous symptoms. Pneumonia and typhus fever end typically in this way. Other fevers, of which typhoid is an example, end by a gradual subsidence of the temperature known as *lysis*, the sick person becoming better each day for a week or so till the normal is reached.

The term *exanthemata* is applied to that group of fevers which are characterised by a distinctive rash—e.g. scarlet fever, measles, smallpox. All these and some others, in which the temperature,

after rising to a certain point, remains more or less steady there for some days, are known as *continued fevers*. Some attacks of fever tend to have a distinct fall of temperature every day, and this type, frequently seen, for example, in the disease called *emphyæma*, is known as *remittent fever*. *Hectic fever*, which occurs in advanced consumption, with a high rise by day and a fall of temperature below normal, accompanied by profuse sweating in the early morning, is of the remittent type. *Intermittent fever* is one in which there is periodically a complete subsidence of the symptoms with recurrence at regular intervals. This is specially characteristic of the malarial fevers, and these are named *quotidian* if the fever recurs each day, *tertian* if it recurs on the third, fifth, &c., days, and *quartan* if on the fourth, seventh, &c. These periodic returns of the fever depend on the length of time necessary for a cycle of development to take place in the parasites which cause the disease. The term *malignant*, when applied to fevers, is indicative of special severity.

As regards treatment of the fever, the condition being in mild degrees simply a manifestation of the reaction of the body to the disease, no treatment beyond means intended for the comfort of the sick person are, as a rule, necessary. The continued fevers run a course of more or less definite duration, and in general sponging with tepid water to keep the skin clean, the administration of mild diaphoretic and diuretic medicines, the maintenance of the recumbent position in bed, and careful restriction of the diet to milk, light soups, and farinaceous materials afford all the treatment that is necessary. Among the drugs frequently used may be mentioned milderer spirit, sweet spirit of nitre, salicylate of soda, and aceto-salicylic acid, better known as aspirin. When the fever is undesirable but not dangerously high, some of the coal-tar derivatives are frequently administered, e.g. antipyrin, phenacetin, &c. Quinine, as well as having a general application in feverish states, is the drug used *par excellence* in malaria with the object of killing off the parasite to which the attacks are due.

When the temperature has reached an alarming height, and especially in cases where the heart's action is much weakened, the use of these 'febrifuge' drugs is not admissible, and the great remedy is to cool the patient by the bath. The fevered person is usually placed in water at about the normal temperature of the body; and, by adding cold water, this is cooled down to a temperature of 60° or 70° Fahr. The relief to the patient is remarkable, the body parts rapidly with its superfluous heat, and general improvement takes place. This lasts for several hours, after which the bath may be repeated if necessary. The same result is attained by the use of the wet-pack, which consists in a wet sheet wrapped round the patient as he lies on the bed.

Fever-bush (*Lindera Benzoin* or *Benzoin odoriferum*), a shrub common in the northern United States, remarkable for its graceful form and beautiful leaves. A decoction of its aromatic and tonic bark is used as a stimulant in fevers.

Feverfew (*Matricaria—Pyrethrum—parthenium*), a composite perennial, common in hedgebanks and waste places, but in Britain usually as a garden escape. It is closely allied to camomile, and still more to wild camomile (see CAMOMILE), and like these is of immemorial use in medicine as a tonic and bitter, its popular name recording its febrifugal properties. Like many other popular medicines, it has now been replaced by more potent remedies, save occasionally in the domestic practice of country districts, or in

that of the herbalist. A double variety is not uncommon in gardens. The Mayweed (*M. inodora*) with leaves more resembling those of camomile, but almost scentless, and large flowers with white ray and yellow disc, is common in cornfields and waste places in Britain and throughout Europe. See PYRETHRUM.

Feverwort (*Triosteum perfoliatum*), a perennial of the order Caprifoliaceæ, a native of North America, where its dried and roasted berries have been occasionally used as a substitute for coffee; its roots act as an emetic and mild cathartic. It is sometimes called *Tinker's Root*, from the physician who first brought it into notice.

Common Feverfew
(*Matricaria parthenium*).

Fez, or more properly FAZ, one of the capitals of the sultanate of Morocco, lies inland in 34° 6' N. lat. and 4° 58' W. long., about 100 miles E. of Rabat on the Atlantic. Standing in a pear-shaped valley surrounded with hills, which are clothed with orchards of orange, pomegranate, apple, and apricot trees, and with olive-gardens, whilst the plain is strewn with numerous ruined buildings, Fez presents a strikingly oriental appearance. The town itself, divided into two parts by a little stream that joins the Sebu 2½ miles to the NE. of the town, is encircled by crumbling walls, and has narrow, dirty, sunless streets. For more than a thousand years Fez has been one of the sacred cities of Islam, being especially renowned for its university and schools of learning. The university, attached to the mosque of the Cherubim, called also the mosque of Muley Edris (one of the largest and most venerated in North Africa) was founded in 859; at present it is frequented by about 1500 pupils, who come from all parts of the Mohammedan world. Attached to this mosque is a library, computed to contain 30,000 MSS. Besides the university there are also fourteen colleges. The extensive palace of the sultan is now partly in ruins. A railway from Fez to Rabat by Mequinez was completed in 1915. Fez is one of the busiest commercial towns of north-west Africa; its merchants import European manufactured wares and the productions of tropical lands, which they despatch by periodical caravans to Timbuktu and the interior of Africa, and export (since 1885 very largely by way of Rabat, instead of as formerly by Tangier) the products they receive thence in return, such as fruits, gums, ivory, gold, together with those of the native industries, chief amongst which are morocco leather, fez caps, pottery, and gold and silver wares. The population is very variously estimated from 150,000 to 50,000; a native computation in 1898 puts it at only 24,000, embracing Arabs, Berbers, Jews, and Negroes. Fez was founded by Muley Edris in 808, and was the capital of the Edrisi dynasty as long as it lasted. Towards the end of the 11th century the town was made the capital of an independent kingdom, founded (1086) by the Almoravid prince, Yussuf ibn Tashfin, and from that time onwards it ranked, on account both of the veneration it was held in as a sacred city and of its learning, as one of the first cities of Islam. But from the date of its incorporation with Morocco, in 1548, it began

to decay in importance. It was occupied by a French relieving force in May 1911. See Meakin's books (1899-1902), and other works named at the article MOROCCO.

Fez, a red binless cap of fine wool, fitting closely to the head, with a tassel of black or blue, worn in Turkey (till 1924), Persia, Greece, Albania, Egypt, and on the shores of the Levant generally. The name is derived from the town of Fez, where such caps were long made; at present the best are manufactured in Tunis, but fezes of fair quality are prepared in Germany, France, and Switzerland. In Africa they are usually called *tarbûsh*.

Fezzan, a province of North Africa, transferred in 1912 from the Turkish empire to Italy, is politically attached to Tripoli, to the south of which country it lies. Extending some 390 miles N. and S., and some 300 E. and W., Fezzan belongs to the desert region of North Africa. It consists of a huge depression, fenced in on all sides except the west by low ranges of hills, and traversed by barren, stony, shelterless plateaus, between which lie long shallow valleys, containing numerous fertile oases. The northern barrier of the province is the range of Jebel es-Soda, which strikes off nearly due east from the south-east corner of the Saharan plateau called the Hammada el-Homra, and is continued towards the south-east by the Haruj el-Aswad. The Jebel es-Soda measures about 125 miles in length, and has an average altitude of 2950 feet. South of this range stretches for some 80 miles a series of low elevations, strewn with smooth stones, destitute of water, and almost entirely devoid of plant and animal life; beyond these again comes a region of sandy alluvial soil, containing saline deposits, with a tolerably good supply of water at 10 to 12 feet below the surface. South of the Hammada el-Homra Fezzan is invaded by the *edeyen* or Saharan sand-dunes; and these are separated from the Hammada of Murzuk on the south by the Wady Ladshal, a watercourse extending north-east for about 125 miles. The southern border of the province is formed by the Tûmmo Hills, more than 2500 feet high, which connect the Ahaggar plateau in the north-west with the mountainous region of Tibesti in the south-east. The entire region slopes gently towards the east.

The oases, mostly depressions in the valleys, are the only cultivated spots, where a little grain and a few vegetables are raised, and where grows the date-palm, the principal source of food for the inhabitants and their domestic animals. Of these camels, poultry, and pigeons are alone kept in any great number. The climate is on the whole uniform and healthy. Fezzan is both hotter in summer and colder in winter than Tripoli; its temperature ranges from 23° to 112°, the annual mean being 70° F. The atmosphere is very dry: rain scarcely ever falls. The principal winds blow from the south and east, but from December to April north and west winds are very prevalent. There is no industry, no export trade except in soda, obtained from extensive salt lakes north-west of Murzuk, and very little commerce. Formerly, however, the Fezzan merchants occupied a very important position as intermediaries in the trade between Tripoli and Egypt on the one hand, Bornu and Timbuktu on the other; but the opening of new routes and the attempts to check the trade in slaves—the great staple of this route—have destroyed the commercial importance of Fezzan. The inhabitants, variously estimated at from 50,000 to 200,000, are a mixed race, embracing Tuareg, Tibbu, Bornu, Haussa, and Arab elements grafted on the original nomadic stock. They are frivolous, pleasure-loving, and idle, but noted for their honesty and good-nature, as well as notorious

for their immorality. In their manners and social customs they have borrowed largely from Arab originals; in religion they are Mohammedans of the Sunnite creed. The principal town of the province is Muzuk (pop. 5000).

Fezzan is the ancient Phazania, or the land of the Garamantes, who were conquered by the Roman Balbus in 20 B.C. In the 7th century the country was subdued by a lieutenant of 'Amr, the Moslem conqueror of Egypt. From the 10th century onwards, except in the 13th century, when it was held by the kings of Kanem, Fezzan was ruled by native or Arab dynasties. From the 16th century its history was a series of struggles against Tripoli, until in 1842 it became Turkish, in 1912 Italian.

Festiniog. See FESTINIOG.

Fiacre, or FIACRACH, ST., an Irish hermit who settled near Meaux in France, building a small monastery there. He died about 670, and from the 9th to the 17th century was famed as a worker of miracles, especially curing a kind of tumour. His shrine, ultimately deposited in the cathedral of Meaux, was long an object of pilgrimage. His name has been oddly perpetuated in connection with Cabs (q.v.) and Hosiery (q.v.).

Fiars (connected with the French *affourage*, 'taxation,' and the English *feor*) is a term meaning 'prices,' and now in Scotland used to denote the prices of grain fixed annually, mainly for the purpose of settling the rate at which the stipends of the parochial clergy are converted into money. The *fiars* prices are the prices of the different kinds of grain of the growth of each county for the preceding crop, as fixed by the sentence of the sheriff, proceeding on the report of a jury summoned for the purpose, before whom the evidence of farmers and corn-dealers is produced. The original use was to fix crown rents, but at an early date the system was applied to church stipends. See TENDS. *Fiars* prices, in addition to being the basis for payment of stipend, are also used in varying degrees in different districts in connection with the payment of grain rents of farms, and in the settlement of valuations as between landlord and tenant or incoming and out-going tenants.

The procedure in 'striking the fiars' is regulated by Act of Sederunt, 21st December 1723, re-enacted by the Codifying Act of Sederunt, 1913. The time fixed by this act for summoning the jury is between the 4th and 20th of February, and the sentence of the sheriff, applying the verdict of the jury, and fixing the fiars prices for the preceding crop, must be pronounced before the 1st of March. The sheriff selects a jury of fifteen, of whom eight are heirs, who elect one of themselves as chancellor, receive the evidence tendered, and on that evidence fix or, as it is termed, 'strike' the fiars prices of the several sorts of victual. An Act of Sederunt, 29th January 1918, permits the sheriff, in fixing the fiars prices, to dispense with a jury, and to proceed to fix the fiars prices on such evidence as seems to him proper and sufficient. Since the passing of this act the general practice has been for the sheriff, instead of calling witnesses to attend at the Fiars Court to speak to their individual transactions in grain, to require farmers and others in the various parishes in the county to fill up signed statements giving details of their transactions in the different kinds of grain during the year. The existing system of striking fiars prices is open to adverse criticism, on the ground that it is antiquated in principle, uncertain in results, and troublesome in operation. Remedies were suggested by departmental committees in reports dated 30th August 1901 and 31st May 1911. The report, dated 20th April 1917, of a departmental committee on fiars prices in Scotland sets out the fluctuations in these

prices in recent years. A bill for the standardisation and commutation of victual stipends was brought forward by the Secretary for Scotland in 1920, but was withdrawn. The departmental committee on the endowments of the Church of Scotland in their report, dated 4th April 1923, recommend the conversion of victual stipend into a fixed and permanent money value, on the basis of average value over a period of fifty years up to and including 1922. In England, under the Tithe Commutation Acts, one set of values, based on an average of the preceding seven years, is fixed for the whole country (see TITHES). See Paterson, *Historical Account of the Striking of the Fairs in Scotland* (1852); *Fairs Prices*, by William Hector; *Position of Fairs Prices and Conversion of Grain Payments*, by N. Elliot (1879). For the fairs prices prior to 1776, see Bald's Tables. See also Taylor's *Tables of Value of Tithe Rent Charges* (1879), and, for fairs prices in the several counties of Scotland, see annual issue of Oliver and Boyd's *Edinburgh Almanac*.

Fiasco, a term borrowed from the usage of the Italian theatre, and now naturalised in France, Germany, and England, for a failure in acting or singing, or by extension of the metaphor for a failure of any kind. In Italy it is not uncommon to hear an audience cry out, 'Olà, olà, fiasco,' even when the singer has only made a single false note. The word means literally 'a bottle,' and its metaphorical use may contain an allusion to the bursting of a bottle.

Fiat, in English law, a short order or warrant of a judge or public officer for making out or allowing processes, letters-patent, &c.

Fiber. See MUSQUASH.

Fibre. See FIBROUS SUBSTANCES, MUSCLE.

Fibrin is a protein substance appearing in the blood during coagulation. In blood, which has escaped from a blood-vessel, there appears, in the course of a few minutes, a fibrous network, which, with the corpuscular elements of the blood enmeshed in it, becomes denser and undergoes contraction, forming the clot. Fibrin is the material of which this fibrous network is composed.

Fibrin is most easily prepared by whipping blood during coagulation with a bundle of fine twigs. The fibrous, elastic threads, as they are formed, adhere to the twigs, and the resulting mass of fibrin may then be freed from the other components of the blood by washing in water. It is a stringy, elastic, white substance, insoluble in water, alcohol, or ether, soluble in dilute salt solution, and precipitable by saturation with sodium chloride or magnesium sulphate, reactions which place it in the globulin class of proteins.

Fibrin arises from a substance of apparently similar chemical nature, *fibrinogen*, which is normally present in the circulating blood. On examining coagulating blood with the ultramicroscope the fibrin is seen to be deposited as very small needles, at first exhibiting some freedom of movement, but, rapidly becoming more numerous and interlacing with one another, ultimately forming a stationary mass. The process is apparently one partly of crystallisation and partly gelatinisation.

The conversion of the fluid fibrinogen to the solid fibrin is brought about by a substance, *thrombin*. Thrombin is not present as such in circulating blood, but again is formed from a precursor *prothrombin*. Two views exist as to the cause of the transformation of prothrombin to thrombin in shed blood. According to one of these, there arises from the blood-platelets, which are in great part destroyed when blood is shed, a substance *thrombokinas*, which, reacting with the prothrombin in the presence of calcium in the ionic state, changes the prothrombin to thrombin. According to the

other view, prothrombin and ionic calcium in themselves can produce thrombin, but are prevented from doing so in the circulating blood by the presence of a substance of phosphatide nature. On the escape of blood from a vessel, there is produced, either from the disintegrated blood-platelets or the injured tissues, a substance, also of phosphatide nature, and probably identical with the phosphatide *cephalin*, which has the property of neutralising the antiprothrombin substance, thus allowing the prothrombin-thrombin change to proceed.

Fibroline, a yarn made from flax, hemp, and jute waste, and used with linen or cotton yarn for the backs of carpets and such-like purposes.

Fibrous Substances (all except asbestos animal or vegetable) owe to a peculiarity of structure their capacity for being spun, woven, and felted. Human hair or horse-hair is not suitable for ordinary textile fabrics, because either resembles a very thin flexible rod with smooth sides, so that when an attempt is made to twist a number of them into a yarn, or form them into a felted substance, they will not hold together. Horse-hair used singly is made into cloth because it is exceptionally strong. But nearly all fibres suitable for woven or felted fabrics, such as wool, silk, cotton, or flax, have on their surface serrations or projections of some kind, or they have a proneness to twist and curl, either of which characters causes them to interlock, so that when they are spun into yarn they do not untwist again. These little prominences or projections are only seen when the fibre is highly magnified.

In addition to suitable structure, the value of a fibre for industrial purposes depends upon its strength and elasticity, and upon its capability of being bleached and dyed. Length and fineness are also considered, as well as abundance of supply.

The wool of the sheep and the shawl goat is described under WOOL and KASHMIR GOAT. See their respective heads for alpaca, mohair, fur, and silk. There are a few other animal fibres of some interest or importance, such as camel's hair, from which an excellent cloth is made, and cow-hair, which is used in considerable quantity for inferior kinds of woollen goods. A fibre of a silky nature is obtained from the byssus of a large Mediterranean bivalve shell-fish (*Pinna nobilis*), which is made into shawls and gloves.

Different parts of plants yield fibres. Only dicotyledonous plants have a true bark, and from these come the most important textile fibres of vegetable origin. These generally consist of strong, fine, flexible bast fibres from the bark sheath, of which flax, hemp, reha, and jute are examples (see BAST). The most valuable of all, however—viz. cotton, consists of hairs which surround the seeds of the plant. In monocotyledonous plants, which also yield many serviceable fibres, these are commonly obtained from the fibrous portions of leaves and of leaf-stalks. More rarely they occur as hair-like fibres which form appendages to leaves or surround their base. Coir (q. v.) fibre is from the husk of the nut of the coconut palm.

Vegetable fibres consist essentially of Cellulose (q. v.), a substance which is not easily acted upon by chemical reagents such as affect allied bodies found in plants. This is an important property in connection with some of the manufacturing processes through which they require to pass.

During the Great War, under stress of shortage of raw materials, various fibrous substances, which had never before been used, or only in some slight measure experimented with, were pressed into service, in Central Europe more especially, in the production of textiles, paper, explosives, &c. Experiments were made, too, in deriving foodstuffs

from fibrous materials hitherto classed as indigestible, and cattle foods of this description were indeed actually adopted.

Cotton, flax, hemp, jute, sisal hemp, and cotton-grass are described under these heads; ramie, rhea, or China-grass under *BEHMERIA*; and New Zealand flax (*Phormium tenax*) under *FLAX*. The vegetable fibres noticed in what follows, though less known than those used in our principal textile industries, are nearly all of some importance commercially. Besides these there are quite a number of plants yielding fibres known to have valuable properties which have not, except in the countries in which they grow, received any industrial application.

FIBRES FROM DICOTYLEDONS.—*Asclepias syriaca* (Silk Weed).—The seeds of this plant are covered with a silky down which is used for a variety of purposes, such as the stuffing of beds and for mixing with wool for certain kinds of cloth and felt. The species is a native of Syria, but is also found in North and South America, and is cultivated in some parts of Europe.

Beaumontia grandiflora is another plant yielding a hairy or silky fibre from the seeds. This is considered to be one of the best and strongest of the seed-hairs called 'vegetable silk.'

Broussonetia papyrifera (Paper Mulberry).—A fine white cloth called *tapa* is made in a number of the Pacific Islands by beating the bark of this tree. The bark of this and another species of *Broussonetia* is much used for making paper in Japan. The fibrous portion of the bark of the young shoots of white mulberry (*Morus alba*) has been used as a textile material in Italy (see *MULBERRY*).

Crotalaria juncea (Sunn Hemp).—Indigenous to Southern Asia and the tropical portion of Australasia; cultivated all over India. The fibre is very suitable for cordage, considerable quantities being exported from India for this manufacture.

Daphne longifolia, *D. papyracea*, *D. Wallichii*.—The fibre of the bark of each of these Indian plants is used in the manufacture of paper and ropes.

Eriodendron anfractuosum (Silk-cotton tree).—This is a tropical American tree of the order *Bombacaceæ*, whose seeds are covered with silky hairs, used for stuffing cushions, &c. The cotton-tree of India and Ceylon, *Bombax malabaricum*, is used in the same way.

Hibiscus cannabinus (Hemp-leaved hibiscus, Deccan hemp).—In Bombay, the Central Provinces, and Madras (regions unsuitable for jute-growing), this small herbaceous shrub is largely cultivated for its fibre, which is used as a substitute for jute. It is rather coarse and harsh, though strong. In India it is made into ropes, sackcloth, and nets, and largely into paper.

Humulus lupulus (Hop).—From the hop vine a useful fibre is obtained, which is turned to account for making cloth in Sweden. In England it has been made into millboard.

Tilia europæa (Common Lime-tree).—The bast fibres of this tree are extensively used in Russia for mats, ropes, and other purposes.

FIBRES FROM GYMNASPERMS.—*Pinus sylvestris* (Pine-wood).—Fibre obtained from the leaf-needles of the Scots pine has, on the continent of Europe, been made into a blanket stuff for hospitals, flannels, and hosiery. It is usually mixed with cotton or wool. The material is believed to have medicinal properties.

FIBRES FROM MONOCOTYLEDONS.—*Agave americana* (Spanish aloe).—An excellent fibre is obtained from this plant, which grows in great abundance in all parts of tropical America. It has also been successfully introduced into some countries of the Old World. The fibre is made into ropes, twine, and netting, as well as into matting and imitation haircloth.

Agave mexicana.—A plant distinct from the last, though often confounded with it. The fibres of both are used for the same purpose. Paper was made by the ancient Mexicans from *A. mexicana* in the same way as the Egyptians made it from the papyrus.

Attalea funifera (Piassava).—From this palm much of the cordage used on the Amazon River is made. The strong fibres used surround the young leaves. These are known in commerce as piassava fibre, or at least one kind of it, which is used in Europe chiefly for brushmaking. Another kind of piassava is got from *Leopoldinia piassava*, also a Brazilian palm.

Bromelia ananas (*Ananassa sativa*) (Pine-apple).—In some places, such as the Bahamas and India, this plant is cultivated for its fruit, but in Malacca, Java, China, and some other eastern places chiefly for its fibre. Several species of bromelia yield useful fibres. The *B. pigna* of the Philippines yields the fine thread from which the costly pina cloth or pina muslin is made. *B. sylvestris*, called in Central America the *ptia*, and in Mexico the *istle*, also produces an excellent fibre.

Carludovicia palmata (Panama screw-pine).—The unexpanded leaves yield the straw of which Panama hats, so much valued for their durability, are made.

Caryota urens (Kittool).—From the leaves of this Indian palm the kittool fibre, now largely used to mix with bristles in brushmaking, is obtained. Strong ropes are made of it in India.

Copernicia cerifera (Carnauba or Carnahuba —q.v.—palm).—A Brazilian palm remarkable for the number of useful products obtained from it. In that country the fibres of its leaves are used for ropes, mats, brooms, &c.

Corypha australis (Australian cabbage-palm).—The fibre obtained by splitting the leaves is made into clothing, netting, and hats.

Macrochloa tenacissima (Esparto-grass).—Esparto fibre is now manufactured into Paper (q.v.) on a great scale. For this purpose it is extremely well suited, being fine and strong, with a tendency to curl. Until comparatively recently much of the esparto-grass of commerce was supposed to be the *Lygeum spartum*, an allied plant.

Musa textilis (Manilla hemp).—The chief use of this fibre is in ropemaking, but matting is also made from it on a considerable scale in Dundee. It is prepared from the leaf-stalks of a wild plantain growing in the Philippine Islands.

FIBRE FROM A FLOWERLESS PLANT. *Cibotium barometz* (Pulu fibre).—The fibre so called surrounds the stalks of the fronds (leaves) of the plant, which is a fern growing in the Sandwich Islands. This fibre, like some of those occurring as hairs on seeds, is called 'vegetable silk.' It is used in the United States and Australia for stuffing in upholstery work.

Fibro-vascular Bundle. See *LEAF, STEM, BARK, VEGETABLE HISTOLOGY, &c.*

Fib'ula, a clasp or buckle (see *BROOCH, BUCKLE*). For the bone so called, see *LEG*.

Fichte, JOHANN GOTTLIEB, a distinguished German philosopher, was born at Ranmenau, near Bautzen, in Upper Lusatia, 19th May 1762, of a family distinguished for their simple piety, uprightness, and firmness of character. His earlier years were marked by a love of solitary musing and meditation. In 1774 he was placed at the gymnasium of Pforta, near Naumburg; and in 1780 he entered the university of Jena, where he devoted himself at first to theology, but afterwards to philosophy. During the years 1784-88 he supported himself in a precarious way as tutor in various Saxon families. Subsequently he went to Zurich in a similar capa-

city, where he first met Johanna Maria Rahn, who afterwards became his wife. Circumstances preventing their immediate union, Fichte in 1791 accepted a tutorship at Warsaw, in the house of a Polish nobleman. The situation proving disagreeable, it was thrown up, and Fichte proceeded to Königsberg, where he had an interview with Kant, of whom he had become an ardent disciple. At first he met with a rather chilling reception. With the view of establishing a better understanding, he resolved to write his 'Critique of all Revelation' (*Kritik aller Offenbarung*), published in 1792. Kant, on the work being submitted to him, praised it highly, and ultimately recommended Fichte to his own publisher, Hartung. In the meantime, however, Fichte's available means of subsistence being exhausted, he was forced to ask the loan of a small sum of money from Kant, which the latter refused. A temporary appointment as tutor in the family of the Count of Krokow, near Danzig, relieved him from immediate difficulties; and the high literary fame which rapidly followed the publication of the *Kritik* having opened to him a new career in life, he returned to Zurich in 1793, where on 22d October he married Johanna Rahn. In 1794 he was appointed to the chair of Philosophy at Jena, where he commenced to expound his system of transcendental idealism. His prelections were distinguished by singular earnestness and oratorical power, combined with the enunciation of the loftiest moral principle.

He now clearly broke away from the limitations of the Critical Philosophy of Kant, of which he had already declared, writing to Niethammer in 1793: 'My conviction is, that Kant has only indicated the truth, but neither unfolded nor proved it.' His 'Doctrine of Knowledge' (*Wissenschaftslehre*, Jena, 1795), his work on the 'Foundation of Natural Rights' (*Grundlage des Naturrechts*, 1796), and the 'Ethical System' (*System der Sittenlehre*, 1798) contain a systematic exposition of his philosophy in its earlier form, expressed in an abstract and somewhat repellent terminology which was laid aside in his later and more popular works. In 1799 an absurd accusation of atheism, fervidly but fruitlessly refuted, led to his removal to Berlin, where he delivered lectures on philosophy to a select auditory. In 1800 appeared his work 'On the Vocation of Man' (*Ueber die Bestimmung des Menschen*). In 1805 he obtained the chair of Philosophy at Erlangen, with the privilege of residing at Berlin during winter. Here he delivered his celebrated lectures 'On the Nature of the Scholar' (*Ueber das Wesen des Gelehrten*, 1805-6). In 1806 appeared his 'Characteristics of the Present Age' (*Grundzüge des gegenwärtigen Zeitalters*), and in the same year his 'Way to the Blessed Life, or the Doctrine of Religion' (*Anweisung zum seligen Leben oder Religionslehre*). In these works we find the highest expression of his philosophy in its mature form, divested of the earlier technicalities. In his relation to the public events of his time Fichte exhibited a high-toned and earnest patriotism. The victories of Napoleon at Auerstadt and Jena drew forth the famous 'Addresses to the German Nation' (*Reden an die Deutschen*). In these addresses, following out the leading idea of his 'Characteristics,' Fichte summoned his fellow-countrymen, in tones of spirit-stirring enthusiasm, to the duty handed down to them from past ages, of founding an empire of reason in which mind alone should assume the guidance of human affairs. With impassioned eloquence he pointed out the true means of national regeneration in a system of public education, of which he laid down the plan and delineated the chief features. His patriotic zeal was fully appreciated by the king, who on the restoration of peace requested

him to draw up a constitution for a new university in Berlin. In 1810 the university was opened, with a host of brilliant names, Fichte, Wolff, Müller, Humboldt, De Wette, Schleiermacher, Neander, Klaproth, and Savigny. By the votes of his colleagues, Fichte was unanimously elected rector. Here, as at Jena, he laboured with unrelenting energy for the suppression of all those customs which he deemed barbarous in themselves, and incompatible with the true idea of a scholar. But his public career came to a premature close. In 1813 the war of independence broke out, and the hospitals of the Prussian capital were soon crowded with patients. Fichte's wife was one of the first who offered her services as a nurse. For five months she tended the sick with all the patient tenderness and devotion of her nature. At last she was seized with fever, 3d January 1814. After a fearful struggle she recovered; but her husband caught the infection, and in spite of all remedies sank under its influence, and died 27th January 1814. Of Fichte it may be said that he combines the penetration of a philosopher with the fire of a prophet and the thunder of an orator; and over all his life lies the beauty of a stainless purity. See *Fichtes Leben*, by his son (1831); and Dr William Smith's *Memoir*, prefixed to his translation of the *Popular Works* (4th ed. 1889).

The fundamental idea of the *Wissenschaftslehre* in its earlier form is that of a primitive act of consciousness; the *Ego*, or I, posits itself—it affirms itself, simply and unconditionally. But in this self-affirmation it necessarily posits a negative—a *Non-ego*—an opposite which is not itself. This activity of the *ego* is its very essence, the necessary condition of its existence. It is itself the absolutely productive, which, however, would not attain to consciousness of itself—i.e. of its infinite spontaneous activity, did it not at the same time place in contrast to itself, and as an impediment (*anstoss*) and limit to its activity, the non-ego—i.e. the objective world, or nature. The *ego*, in so far as it is determined by the non-ego, is the intelligent *ego*, and, as such, the subject of theoretical science—the science of cognition; the *ego*, on the other hand, as determining the non-ego, is the subject of practical science—the science of the will. Freedom, absolute, spontaneous activity, for its own sake, is not with Fichte, as with Kant, the condition and presupposition of moral action, but is itself the highest expression of the problem of the moral law. To realise this self-activity, however, the *ego* requires an external world of objects, in order that in them as limits it may become conscious of its own activity. Generally speaking, Fichte makes that which, from the standpoint of ordinary consciousness, we call the world merely a product of the *ego*; it exists only through the *ego*, for the *ego*, and in the *ego*. In his later and more popular writings, from 1800 onward, Fichte's transcendentalism assumes a more profoundly religious character, the centre of the system being now an *Absolute Ego*, in whose self-determination all the *Non-ego* is determined—the One Universal Being or God, of whom all finite existence is but a manifestation—the vesture of the Infinite. This transition first appears in his *Bestimmung des Menschen* ('Vocation of Man,' 1800), and is more fully developed in the *Wesen des Gelehrten* and the *Religionslehre*; and it is also set forth in a strictly scientific manner in the *Nachgelassene Werke* (1835), in which his *Speculative Logik* and his revised theory of right and morals are particularly deserving of attention.

Although Fichte never, strictly speaking, formed a school, his influence upon the subsequent development of German philosophy has been very im-

portant; and indirectly, through the writings of Thomas Carlyle, he has exercised a marked and important influence on the course of recent thought both in Great Britain and America. Fichte's doctrine of the Divine Idea of the Universe underlies Carlyle's most impressive teachings regarding human life and duty. His popular works have been translated into English by Dr William Smith; their titles are: *The Vocation of the Scholar*; *The Nature of the Scholar*; *The Vocation of Man*; *The Characteristics of the Present Age*; and *The Way to the Blessed Life, or the Doctrine of Religion* (4th ed. 1889). An American translation of the *Wissenschaftslehre* and the *Naturrecht*, by A. E. Kröger, appeared at Philadelphia in 1868-69 (reprinted London, 1889). An admirable monograph of Fichte, by Professor Adamson, forms one of the volumes of Blackwood's *Philosophical Classics* (1881).

IMMANUEL HERMANN VON FICHTE, son of the former, was born at Jena, 18th July 1797. Occupied at first as a teacher, he was appointed professor of Philosophy in Bonn in 1836, and from 1842 to 1863 held a chair in the university of Tübingen. He was ennobled in 1867, and died at Stuttgart, 8th August 1879. He wrote works on speculative theology (1847), ethics (1850), anthropology (1856), psychology (1864), the immortality of the soul (1873). In philosophy he occupies the position of a mediator between an extreme monistic and an equally extreme individualistic metaphysic, between pantheism and deism, between Hegel and Herbart. The great aim of his speculations was to find a philosophic basis for the personality of God, and for his theory on this subject he proposed the term *Concrete Theism*, to distinguish it alike from the abstract theism which makes God almost an unreality—a barren aggregate of lifeless attributes—and, on the other hand, from the all-absorbing pantheism of Hegel, which swallows up the human and the divine in its own inapprehensible totality.

Fichtelgebirge, a mountain-system, chiefly situated in the N.E. of Bavaria, once covered with pines (*Fichte*, 'pine'), and constituting a watershed between the head-feeders of the Elbe, the Rhine, and the Danube. Roughly speaking, it forms a rhomboid, lying between Hof, Baireuth, and Eger, its intersecting axes being disposed N.E.—S.W. and N.W.—S.E. The length of each axis thus measured is about 24 miles. The main chain forms the N.W. fringe of the system, and at its S.W. extremity wheels round so as to present a N.W.—S.E. strike, the average elevation of the peaks ranging from 2700 to 3200 feet. The highest summits are Schneeberg (3461 feet) and Ochsenkopf (3334). On the S.W. edge the system falls away by steep gradients; but in the opposite direction its descent is much more gradual, the hills in the N.E. averaging an altitude of 2000 to 2300 feet. In their northern extremities the Fichtelgebirge are connected by intermediate chains, on the one hand with the Erzgebirge, and on the other with the Thuringian Forest. Geologically they are composed principally of granite and primitive crystalline slates, with which are conjoined bands and intrusions of gneiss, micaceous slates, basalt, and some strata of the Tertiary age (*Oligocene*). The climate of the region is decidedly raw and cold; snow lies on the summits as a rule from October to May. Owing to the extensive forest tracts and the moory soil, mists are of common occurrence. The only industries carried on by the inhabitants are those connected with mining (chiefly iron and stone quarries), with the exploitation of the forests, and with the manufacture of glass. Of recent years the Fichtelgebirge have come much into vogue with tourists. See Schmidt's Guide.

Ficino, MARSILO, an illustrious philosopher of the Italian Platonic school, was born at Florence in 1433. The son of the principal physician of Cosmo de' Medici, he was appointed by that prince in 1463 president of a classical academy (founded 1440) having for its aim the diffusion of the Platonic doctrines, which Ficino held to be the basis and confirmation of the Christian system; and at his suggestion he undertook the translation of Plotinus, Iamblichus, Proclus, and Porphyry, besides a Latin but by no means literal version of Plato. On the death of Cosmo, Ficino found a no less munificent patron in this prince's grandson, Lorenzo de' Medici; and having, at the mature age of forty, decided on entering the church, he was endowed by Lorenzo with the rectorship of two churches in Florence, and a canonry in the cathedral. His theological doctrines, while undoubtedly sincere, present a strange medley of incongruous views, the natural result of his attempt to fuse the philosophy of Plato with the Christian creed. He died in 1499. His collected works were published at Basel (1491, and in 1561-76), and consist of translations from the Greek philosophers, and original metaphysical and theological compositions, of which may be named *Theologica Platonica seu de immortalitate animarum ac eterna felicitate*. See R. L. Poole's *Medieval Thought in Theology* (1884), and the books named at MEDICI.

Fick, AUGUST, an eminent philologist, was born at Petershagen, near Minden, 5th May 1833, studied philology under Benfey at Göttingen from 1852 to 1856, and taught in the gymnasium until his appointment as professor of comparative philology in the university there in 1876. In 1887 he was called to a chair at Breslau, and he retired in 1891. *Vergleichendes Wörterbuch der Indogermanischen Sprachen* (1870; 4th ed. 1890 *et seq.*), his greatest work, is a stupendous monument of learning, albeit its value is somewhat impaired by the over-ardacity of its reconstruction of the primitive parent-speech. Other works deal with Greek personal and place names, the language of Homer, and the Indogermanic language.

Fiction. See ROMANCES, NOVELS.

Fiction, LEGAL, a supposition of law that a thing is true, which is either certainly not true, or at least is as probably false as true. Fictions have existed in all legal systems. They have served many useful purposes, by enabling individuals who by the strict letter of the law would have been excluded from obtaining redress of evils to procure that remedy by a pious fraud. There are two general maxims which regulate the application of fictions—viz. that no fiction shall be allowed to operate a wrong, and that no fiction shall be admitted which in the nature of things is impossible. The Roman form of judicial procedure abounded with fictions, by which alone, in many cases, a party aggrieved could enforce his right. Thus, an heir, unjustly disinherited, by the *querela inofficiosi testamenti* feigned that his father had been mad. A stranger in Rome who had been robbed could not in early times obtain restitution without the *fictio civitatis*, whereby he feigned himself a citizen. Many of the fictions existing in Rome have found a counterpart in modern systems; thus, the *fictio longæ manûs*, whereby lands at a distance were feigned to be delivered, resembles an English feoffment at law. In like manner, the *fictio traditionis symbolice* of keys of a warehouse to give possession of the articles contained therein, and of a deed in confirmation of the covenants contained therein. The 'fiction of the unity of the persons' was the original of the Scottish fiction that 'the heir is the same as the deceased.' But in no system of laws have fictions

been so liberally adopted as in that of England. It was by means of fictions alone that the original limited jurisdiction of the courts of King's Bench and Exchequer was extended to ordinary suits. In the latter court every plaintiff assumed that he was a debtor to the crown, and was debarred from discharging his obligation by the failure of the defendant to satisfy his demand; in the former it was assumed that the defendant had been arrested for some supposed trespass which he had never in fact committed. The fictitious characters of John Doe and Richard Roe long contributed to make the action of Ejectment (q.v.) famous. And though these fictions have disappeared before the ruthless hand of modern legislation, yet to this day in England, in an action at the instance of a father for the seduction of his daughter, damages can only be awarded on the assumption that she was his servant, and that he has suffered pecuniary loss by deprivation of her services. In the law of Scotland fictions of law are not of frequent occurrence. For the benefit of creditors the principle that the heir is 'the same person as the deceased' is admitted; and in an action of 'Reduction-improbation' of a deed it is assumed that the document was false, whether the fact be so or not. The legitimization of natural children by the subsequent marriage of their parents is an instance of a 'retroactive fiction.' See *Maine's Ancient Law*, and Colquhoun's *Summary of the Civil Law*.

Ficus. See FIG; also CAPRIFICATION, INDIA-RUBBER.

Fiddle. See VIOLIN.

Fideicommissum, in the Civil Law, was a conveyance of property in trust to be transferred to a third person named by the trustor. *Fideicommissa*, when first introduced, were not supported by the law. The performance of them depended, therefore, on the conscience of the party intrusted, and consequently they were frequently not carried out. They were originally adopted for the purpose of conveying property either where a party, from the circumstances of the case, as inability to procure the proper number of witnesses, was prevented from executing a will, or where he desired to benefit those who by law were precluded from taking the property. To effect this purpose an actual conveyance was made to a friend, coupled with a request that the property should be transferred to another. *Fideicommissa*, having thus been introduced for a special purpose, were by degrees extended to conveyances of the whole inheritance, and finally were used for the purpose of settling estates in a particular order of succession, forming the earliest instance of Entails (q.v.). *Fideicommissa* first received the sanction of positive law in the reign of Augustus, by whom authority was given to enforce the performance of these fiduciary obligations. A special prætor was afterwards appointed for the enforcement of trusts, and the Emperor Claudius subsequently extended this authority to the consuls and presidents of provinces. *Fideicommissa* were either *particular* or *universal*, the former being a bequest of a particular subject, or a part only of the inheritance; the latter comprehended the whole estate. The *Senatus-Consultum Trebellianum* enabled a person profiting by a universal succession of this kind to sue or be sued as heir.

In Holland the principles of the civil law as to *fideicommissa* form an important branch of the law in regard to landed estates. An heir may be required to transfer either the whole or a portion of his inheritance. The provisions of the *Senatus-Consultum Trebellianum* also have been adopted. Children who have received their legal portions, and are required to transfer to a stranger the rest

of the inheritance, are entitled to retain a fourth part for themselves. Similar provision may be found in the legislation of other countries which follow the civil law. See Hunter's *Roman Law*, and the Dutch and German manuals of Civil Law.

Fidei Defensor. See DEFENDER OF THE FAITH.

Fief. See FEUDALISM.

Field, in Heraldry, the whole surface or content of the escutcheon or shield. See HERALDRY.

Field, DAVID DUDLEY, an American jurist, the eldest son of a Congregational minister (1781-1867), was born in Haddam, Connecticut, in 1805, and was admitted in 1828 to the New York bar, at which he practised until 1885, distinguishing himself especially by his labours in the direction of a reform of the judiciary system. In 1837 he was appointed by the state to prepare a political, civil, and penal code, of which the last has been adopted by New York, and all have been accepted by some other states. In 1866, by a proposal brought before the British Social Science Congress, he procured the appointment of a committee of jurists from the principal nations to prepare the outlines of an international code, which were presented in a report to the same congress in 1873. This movement resulted in the formation of an association for the reform of the law of nations, and for the substitution of arbitration for war, of which Field was the first president (see INTERNATIONAL LAW, CODE). An LL.D. of Edinburgh, he presided over the London Peace Congress in 1890. He died 13th April 1894. His *Speeches and Papers* fill 3 vols. (1884-91).

His brother, STEPHEN JOHNSON FIELD (1816-99), born in Haddam, was for some time a partner in Dudley's firm, and settled in 1850 in California, where he was instrumental in forming the laws of the state, and was judge of the Supreme Court in 1857-59. Appointed chief-justice in 1859, he was raised to the supreme bench of the United States in 1863, and voted with the Democratic minority of the electoral commission in 1877. In 1880 he received 65 votes on the first ballot for the presidential candidate.

Another brother, CYRUS WEST FIELD, was born in Stockbridge, Massachusetts, in 1819, and at the age of fifteen entered the employment of A. T. Stewart, in New York. In the twelve years preceding 1853 he built up a prosperous paper-manufacturing business, from which he then partly retired, only to engage with great enthusiasm in the promotion of the Atlantic telegraph. For this he secured a charter from the colonial government of Newfoundland for fifty years; and, being joined by Peter Cooper and other American capitalists, he organised two great companies for the purpose. Devoting himself entirely to the work of 'moving the New World alongside the Old,' he crossed the ocean repeatedly in order to arouse public interest; and after the final success in 1866 he received from Congress a medal and the thanks of the nation. He helped to develop the elevated railways of New York, but died in straitened circumstances on 12th July 1892.

Field, EUGENE (1850-95), born at St Louis, Missouri, was a journalist at twenty-three, and gave much of his best work to the columns of a Chicago paper, his column of 'Sharps and Flats' being for years a characteristic feature. His work in prose and verse varies from tender pathos and delicate humour to the broadly farcical; he is best known as humorist and as poet of childhood. His best verses for children are those in *With Trumpet and Drum* (1892); *A Little Book of Western Verse* may fairly represent another type of work; and his humour is perhaps best illustrated in *The Love Affairs of a Bibliomaniac*. See his *Poems* (1911).

Field, JOHN, musician and composer, commonly known as Russian Field, was born in Dublin, 26th July 1782. A pupil of Clementi, he accompanied him in 1802 on a continental tour, but, settling in St Petersburg as a teacher of music, remained there from 1804 till 1823, when he proceeded to Moscow; in 1832 he returned to London. Nevertheless in the following year he once more started on a long continental tour, which terminated with his death at Moscow on January 11, 1837. Although Field wrote seven concertos, three sonatas, and numerous pianoforte pieces, he is to-day only remembered as the author of about half-a-dozen *Nocturnes*, which were Chopin's models. Liszt wrote an essay on Field, prefixed to Schubert's edition of the *Nocturnes*, and Spolín in his *Selbstbiographie* (vol. i.) gives some account of him. See *Memoir* by Grattan Flood (1921).

Field, MICHAEL, is the pseudonym of Katharine Harris Bradley (d. 1914) and her niece, Edith Emma Cooper (d. 1913), who, from 1884, wrote in collaboration several remarkable poetic diamas and some beautiful lyrics; notable are *Callirrhoe* (1884), *Fair Rosamund* (1884), *The Father's Tragedy*, *Canute the Great*, *Long Ago*, *The Tragic Mary*, *Sight and Song*, *Wild Honey*, *Poems of Adoration*, *Mystic Trees*, *In the Name of Time*. See *Life* by Mary Sturgeon (1922).

Fieldfare (*Turdus pilaris*), a species of thrush, common in Britain as a winter visitor. It is a native of North Europe, breeding and spending the summer in Scandinavia and other northern countries, but migrating southwards in winter as far at least as the Mediterranean. It is very abundant in Norway, and, contrary to the ordinary habit of thrushes, is social in its nest-building,

Fieldfare (*Turdus pilaris*).

numerous nests being often seen on one spruce-tree. There are no authenticated instances of the fieldfare nesting in Britain. As a winter visitor it has familiarised us with its harsh call-note, but its true melodious song is mostly reserved for the northern summer. The fieldfare is about the size of a blackbird, but has longer wings. The head, neck, and some other parts are grayish; the tail is black, with a white line on the outer feathers; the general upper surface is chestnut brown; the under surface is white, with a reddish-yellow breast streaked and spotted with black. In Britain the fieldfare feeds on worms, snails, and such like, or in severer weather on haws and other available fruits and seeds. It is sometimes tamed as a songster. See THRUSH.

Field-glass. See OPERA-GLASS.

Fielding, ANTHONY VANDYKE COPLEY, water-colour painter, was born in 1787. He came of an artistic family, for his father, T. N. Fielding, was a portrait-painter residing near Halifax, his mother

became a member of the Water-colour Society, and three of his brothers were painters in the same medium. He received his early instruction at home before being placed under John Varley; and, like Turner and Girtin, he worked in the house of Dr Monro. In 1810 he began to exhibit with the Water-colour Society, of which he was successively treasurer and secretary; and in 1831 he succeeded Crisall as president. In one year he contributed to the exhibition of the society no fewer than 56 subjects, occasionally, in addition, sending an oil-picture to the Royal Academy. His early works show breadth, freedom of treatment, and a fine sense of atmosphere; but in later life the quality of his art deteriorated, greatly in consequence of the facile methods and mannerisms into which his practice as a fashionable teacher of painting had betrayed him. He died 3d March 1855.

Fielding, HENRY, born at Sharpham Park, Glastonbury, April 22, 1707, was the son of Lieutenant Edmund Fielding, afterwards a general, belonging to the younger branch of the Denbigh family (whose connection with the Hapsburgs, set to his credit by Gibbon in the *Autobiography* and alluded to in *Esmond*, was proved by Mr Round to be purely apocryphal). He went to Eton, which he left before November 1725; in which month took place at Lyme Regis his attempt to abduct his first love, a relative and an heiress, Miss Sarah Andrew. At Leyden University, where he was admitted a student of literature (not civil law) in March 1728; he was there in 1729, but had left before 8th February 1730. His first comedy, *Love in Several Masques*, was produced at Drury Lane in February 1728, just before he started for Leyden—perhaps the money required was thus raised. *The Temple Beau* appeared in 1730. From this date until February 1735 he wrote a number of comedies and farces, the best of which are *The Author's Farce* (1730), the burlesque of *Tom Thumb*, afterwards *The Tragedy of Tragedies* (1730), *Don Quixote in England* (1734), *The Mock Doctor* (1732), and *The Miser* (1733), two adaptations from Molière, and *The Intriguing Chambermaid* (1734), an adaptation from Regnard. His dramatic works in general bear signs of haste and carelessness. A brief interval in their rapid manufacture was filled by his marriage (28th November 1734) to Miss Charlotte Cradock, a Salisbury beauty and his acknowledged model for the 'Sophia Western' of *Tom Jones*.

For a year or more Fielding appears to have led the life of a country gentleman at East Stour in Dorsetshire, where he had resided as a boy. But his wife's fortune of £1500 was not inexhaustible, and early in 1736 (probably with what remained of it) he took the Little Theatre in the Haymarket, where he brought out two very successful burlesques—*Pasquin* (1736) and the *Historical Register* (1737). The bold satire on the ministry contained in these pieces led to the precipitate passing of the Licensing Act of 1737, which made the consent of the lord chamberlain necessary to the representation of any play. This effectually closed Fielding's theatre, and in November 1737 he became a student of the Middle Temple. He was called to the bar in 1740, and travelled the western circuit. But, though he does not seem to have neglected law, he did not relinquish literature. During his studentship he edited (with James Ralph) the *Champion*, a paper of the *Spectator* type. His real *début*, however, came in 1740, not long after Richardson published his popular *Pamela*. Apt at burlesque and eminently manly, Fielding's genius saw at once how effectively ridiculous the feeble side of Richardson's morality might be made by transferring his heroine's difficulties to a male hero. Designing at first no more than railery, his plan

grew under his hand, and *Joseph Andrews* became a novel of life and manners, with a group of characters, of which one, Parson Adams (based on the writer's friend, William Young) is immortal. His success probably revealed to him a power he had scarcely suspected, and opened a wider perspective of fiction. But for the moment his precarious means prompted no more than the publication by subscription of three volumes of *Miscellanies*, made up mainly of early work. They included another play, *The Wedding Day*, an old comedy revised for Garrick, and produced at Drury Lane without success in February 1743, some essays, some youthful verse, a clever Lucianic fragment called *A Journey from this World to the Next*, and the surpassing study in irony known as the *History of the Life of the late Mr Jonathan Wild the Great*. Despite its maturity, it had probably been written before *Joseph Andrews*, as it seems unlikely that after so signal a success its writer would have essayed a line so different.

From the preface to the *Miscellanies* it is clear that Fielding's circumstances at this date were far from good. His means were uncertain, his health already broken (he was a martyr to gout), and his beautiful wife an invalid. She seems to have died at Bath, and was buried in London, 14th November 1744. Fielding was so heart-broken by her loss that his friends feared for his reason. From the preface to his sister's novel of *David Simple* (2d ed. 1744) he still appears to have hoped for success at the bar. But in 1745 he again drifted into journalism as the author of the *True Patriot*, a government organ, succeeded in 1747 by the *Jacobite's Journal*. In November 1747 he married his wife's maid, Mary Daniel, who had remained in charge of his surviving child, Harriot; and a year later, by the interest of his schoolfellow Lyttelton, he became a justice of the peace for Westminster, moving into a house in Bow Street belonging to the Duke of Bedford. Thence in February 1749 he put forth a second novel, his famous *Tom Jones*, the 'labour,' he says, 'of some years.' Less than three years later came a third novel, *Amelia*. The remainder of his life was a continued struggle with ill-health and a harassing vocation, which he nevertheless followed most assiduously. His further literary efforts are confined to a few pamphlets, philanthropic and professional, and a fresh periodical, the *Covent Garden Journal* (1752). In 1754, sinking under a complication of disorders, but gallantly struggling with his magisterial duties to the last, he quitted England for Lisbon in search of health. After a voyage of many vicissitudes, narrated with the most touching and manly cheerfulness in his posthumously printed *Journal*, he reached the Portuguese capital, where he died two months later, 8th October 1754, aged forty-eight. He was buried in the English cemetery. *Luget Britannia gremio non dari fovere natum*, says the inscription on his tomb.

The only portrait of Fielding is a sketch from memory by his friend Hogarth, whose works he greatly admired. Representing him in later life, it exhibits little more than the shadow of that handsome Harry Fielding who at twenty-two rushed upon London from Leyden in all the ardour of health and animal spirits. He paid the penalty of his youthful appetite for pleasure by a broken and laborious middle age, endured with a courage and fortitude which command respect. Of his work his three novels now chiefly survive. His plays were hasty and ill-considered productions; and he is best in pure burlesque, or when he takes his plot ready-made. His essays and journalism are hack-work. But he is fairly what Scott calls him, the 'Father of the English Novel.' In *Joseph Andrews* he first felt his feet; in *Tom Jones* he perfected his

method and put forth his full powers. When Coleridge extravagantly praised its plot, the modern novel was yet young, and the dictum now needs qualification. But the skill and variety of the book, its close characterisation, its happiness of illustration, and the wealth of wit, wisdom, and irony cannot be contested. There are—and it is to be regretted—pages which show an artistic insensibility, and an over-indulgence to certain forms of masculine frailty which even the manners of the time cannot wholly excuse; but apart from this there is no reason to doubt the sincerity of the moral purpose proclaimed. *Amelia*, a shorter, more subdued, and less elaborated work, has also its admirers. But Fielding put his best 'criticism of life' into *Tom Jones*.

His biography has been written by Murphy (1762), Watson (1807), Lawrence (1855), Austin Dobson (1883; new ed. 1907), Miss Godden (1909), and W. L. Cross (1919). Thackeray's sympathetic lecture and Sir Leslie Stephen's introduction to the *édition de luxe* of 1882 are valuable.

Field-madder (*Sherardia arvensis*, order Rubiaceae), a small purplish weed, common on cultivated lands, of which the root is a substitute for the closely allied true Madder (q.v.).

Field-marshal is now the highest rank of general officer in the British and most foreign armies. In the former it is a special honour only conferred on the ground of distinguished service or royal birth. The etymology of the word *marshal* and the date of the introduction of the rank Field-marshal into the British service are given at MARSHAL. A field-marshal has no higher pay than any other general, except when commanding an army. The insignia of the rank is the baton.

Field-mouse, a name popularly given to certain species both of Mouse (q.v.) and of Vole (q.v.). See also SHREW.

Field-officers, in the Army, are always mounted officers—viz. majors, lieutenant-colonels, and colonels. They command, in the infantry, half-battalions (or wings), battalions, and regiments (see COLONEL) respectively; whilst the captains, lieutenants, and second-lieutenants are called company officers. In the cavalry, artillery, engineers, and other corps, officers bearing the same titles are called field-officers, but their duties and commands are different from those of the infantry.

Field of the Cloth of Gold, the place of a splendid, but fruitless, diplomatic meeting of Henry VIII. (q.v.) of England and Francis I. of France, near Calais, in 1520.

Fields, JAMES THOMAS, American publisher, was born in Portsmouth, New Hampshire, in 1817, and from 1839 to 1870 was a partner in the publishing firm of Ticknor, Reed, and Fields in Boston. He edited the *Atlantic Monthly* in 1862-70, and for many years lectured on literary subjects; and he wrote some books of verse, besides interesting volumes on Hawthorne and Dickens. He died in Boston, 24th April 1881.

Field-train, formerly a department of the Royal Artillery responsible for the custody and supply of artillery ammunition in the field. The duties are now performed by the Ordnance Store Department.

Field-works are intrenchments and other temporary fortifications thrown up by an army in the field, either as a protection from the onslaught of a hostile force, or to cover an attack upon some stronghold. Field-works will be more particularly described under the article FORTIFICATION.

Fieri Facias, WRIT OF. The judgment or order of an English court of law, directing the payment of *money* or *costs*, may be enforced by a

writ of execution called the writ of *feri facias*—often contracted to *fi. fa.* It is, in form, a command by the sovereign to the sheriff of the bailiwick in which execution is to be levied, to 'cause to be made' (*feri facias*) out of the goods and chattels of the debtor the amount of the judgment entered against him, together with interest thereon, as agreed between the parties, or at the rate of 4 per cent. from the day of the judgment or order, or the day from which interest is directed to run. A judgment creditor may sue out this writ immediately after entry of judgment in his favour, except where a time is limited for payment of the judgment debt which has not yet expired, or where the court has ordered a stay of execution. As between the original parties to a judgment or order, execution may issue at any time within six years from the recovery of the judgment or the date of the order.

In regard to the execution of a writ of *feri facias*, the sheriff must seize such quantity of the goods and chattels of the debtor within his bailiwick as will, if sold, be reasonably sufficient to pay the judgment debt and interest. Seizure is effected by the sheriff or his officer taking actual possession of the debtor's movable property. In entering upon the premises where the goods and chattels are, the sheriff must request admission, and is liable to an action of damages if he breaks open an outer door of the judgment debtor's house. But, having once effected an entry, he may break open inner doors and chests, if necessary to his purpose. Possession of the debtor's property must be retained after seizure; and the sheriff may—and, where there is any risk of injury or rescue, ought to—remove the goods for safe custody. If the debtor do not at once satisfy the judgment debt, the sheriff may proceed to sell a sufficient quantity of the debtor's property to meet it; and then, as a matter of practice, he hands over the amount to the judgment creditor without bringing or paying it into court. The Bankruptcy Act of 1883 provides that, where the sheriff sells the goods of a debtor under an execution for a sum exceeding £20, the sale shall be by public auction, and shall be publicly advertised by the sheriff on and during the three days next preceding the sale. Seizure and sale of a debtor's goods under a writ of *feri facias* amounts to an act of bankruptcy. An execution creditor may levy the poundage fees and expenses of execution over and above the sum recovered.

The property legally available for seizure and sale under a writ of *fi. fa.* may consist of (1) goods and chattels in the ordinary sense of the term, such as furniture belonging to the debtor; (2) money, bank-notes, bills of exchange, and other securities; (3) chattel interests in land, such as leaseholds; (4) growing crops, subject to the rent accruing due; (5) shares in ships (the only legal method of selling such shares is by bill of sale).

If goods are removed from lands or premises let on lease, the sheriff must levy sufficient to pay to the landlord the sum due for arrears of rent, provided such arrears do not amount to more than one year's rent. A sheriff may not take in execution (1) manure, hay, &c., where by the covenants of the lease the tenant is restricted from removing them; (2) the wearing apparel or bedding or tools of the debtor, where the value of the whole does not exceed £5; (3) such fixtures as the judgment debtor himself has no right to remove. At common law the writ of *feri facias* 'bound' the debtor's goods from the *teste*, or date of issue; the Statute of Frauds provided that no purchaser should be prejudiced till the writ had actually been delivered to the sheriff for execution; while the Mercantile Law Amendment Act, 1856, enacts that a writ of *feri facias* shall not prejudice the title to goods

acquired *bonâ fide* and for value by any person before the actual seizure thereof under the writ.

Where it appears by the return of a writ of *fi. fa.* that the debtor is a beneficed clerk not having any lay fee within the sheriff's bailiwick, the plaintiff may sue out a writ of *feri facias de bonis ecclesiasticis*, directed to the bishop of the diocese, commanding the debtor to enter upon and hold the benefice till he shall have satisfied the plaintiff's judgment debt out of the rents, tithes, and profits thereof.—In Scotland the corresponding process for seizing and selling a debtor's goods is termed Pounding (q.v.).

Fiery Cross, an ancient summons to arms used in the Scottish Highlands, sent by swift messengers from place to place. It was a small cross of light wood, one extremity of which was set on fire, and the other dipped in the blood of a goat. See Wade's report in *Historical Papers* (ed. Allardyce, New Spalding Club, 1895-96), and for a similar usage among the Goths, Olaus Magnus.

Fieschi, COUNT GIOVANNI LUIGI DE', a member of one of the most illustrious houses of Genoa, was born about the year 1523. In addition to the lustre of ancestral fame, his name has attained a tragic historical celebrity in connection with a remarkable conspiracy of which he was the chief. Andrea Doria, the famous admiral, sprung from a race hereditarily at feud with that of Fieschi, having expelled the forces of Francis I. from the state, had restored the republican form of government, but at the same time, by his vigorous administration, effectually held in check the ambition of the nobles. Count Fieschi organised a plot for the overthrow of Doria (who was supported by the Emperor Charles V.) and the establishment of an oligarchic form of government. Instigated by the approval of France and Rome, Fieschi speedily enrolled a formidable array of accomplices, his three brothers among the foremost. Three galleys, under the pretext of an expedition against the Turks, were fully equipped and filled with mercenaries; and, all being in readiness, the attempt was fixed for the 2d of January 1547. Doria, in spite of repeated warnings, refused to ascribe treacherous or subversive designs to Fieschi. Complete success seemed at first to crown the conspirators; the gates of the city were forced, the fleet captured, Gianettino assassinated, Doria in flight. Fieschi had but to appear and dictate, but he was nowhere to be found. In stepping from one galley to the other in the darkness of night he had stumbled, and, falling overboard, been borne down by his ponderous armour, and miserably drowned in the harbour, or, according to some, stifled in the slime. The scheme ended here, and Doria returned. See DORIA, GENOA; and the monographs of Brea (1863) and Cesalia (1864).

Fieschi, JOSEPH, known by his attempt on the life of King Louis-Philippe, was born in Corsica in the year 1790. He served in Russia in 1812, and on Murat's expedition suffered imprisonment as a thief, but in 1830 got a small government appointment at Paris. Dismissed for fraudulent conduct, he secured accomplices in an audacious plan, and invented an infernal machine with twenty-four barrels, which was fired while the king and his party were passing the house, 28th July 1835. Eighteen people were killed, among whom was Marshal Mortier, but Louis-Philippe himself escaped with a mere scratch. Fieschi was immediately seized, and, along with his accomplices, was tried, condemned, and executed on 16th February 1836. See Ducamps, *L'Attentat Fieschi* (1877).

Fiesolè (Lat. *Fœsulæ*), one of the most ancient of Etruscan cities, is situated on the crest of a hill, about 3 miles N.E. of Florence. Here the Gauls

defeated the Romans in 225 B.C.; and here Hannibal encamped after crossing the Apennines. The city was made a military colony for Sulla's veterans, who twenty years later lent warm support to Catiline. The place was seized by the Goths, and was not captured by Belisarius until after a long siege. Its decay began in the middle ages with the rise and growth of Florence, and it has now only about 10,000 inhabitants, chiefly occupied in straw-plaiting. The sole vestige of Etruscan architecture remaining is the cyclopean wall. The amphitheatre and other remains belong to the Roman age. The town has several buildings dating antecedent to the 15th century, amongst them the cathedral, built in 1028 and restored in 1256; a pretorian palace of the 13th century; and a Dominican (1406) and a Franciscan (1350) monastery.

Fiesole, GIOVANNI DA. See ANGELICO, FRA.

Fife, a smaller variety of the flute, usually with only one key. Fifes were at one time generally used in the army and navy in conjunction with drums, for playing marches and other simple melodies. They are usually pitched in the key of B \flat or C. Originally the fife was made with a cylindrical bore throughout, but this was many years ago superseded by the conical instrument. It is rather curious that the ancient cylindrical bore superseded as unsuitable in the fife should have been resuscitated and perfected in the modern Flute (q.v.). See BAND (MILITARY).

Fife, a maritime, almost peninsular, Scottish county, washed on the N. for 21 miles by the Firth of Tay, on the E. for 24 by the German Ocean, and on the S. for 55 by the Firth of Forth. Its extreme length is 42 miles, its extreme breadth 21, and its area 513 sq. m. The surface offers a succession of cultivated vales and hills, the most prominent eminences being the East and West Lomonds (1471 and 1713 feet), Largo Law (965), and Burntisland Bin (632). Almost the only streams are the Eden (30 miles long) and the Leven (16); whilst of lakelets the chief are Loch Gelly, Loch Pitty, Kilconquhar Loch, and Lindores Loch. Fife rests on the Old Red Sandstone, with trap rocks in the north, Carboniferous strata and trap in the south. Its mineral wealth includes coal (which is largely mined), shale, ironstone, limestone, and freestone. The soil is some of it very fertile, especially in the Howe of Fife, or Stratheden; and whilst barely one-fourth of the whole of Scotland is in cultivation, in Fife the proportion is nearly three-fourths. 'A gray cloth mantle with a golden fringe,' said James VI. of Fife, referring to the many towns and fishing-villages that skirt its ancient sea-margin—Rosyth, Inverkeithing, Aberdeen, Burntisland, Kinghorn, Kirkcaldy, Dysart, Wemyss, Buckhaven, Methil, Leven, Largo, Elie, St Monans, Pittenweem, the Anstruthers, Kilrenny, Crail, St Andrews, Ferryport, Newport, and Newburgh. Inland lie Cupar, Dunfermline, Falkland, Lochgelly, &c. Under those towns are noticed the manufactures, the chief antiquities, the illustrious natives, and the outstanding points in the peaceful history of the 'Kingdom of Fife,' which took so leading a part in the Scottish Reformation. Here, then, we need mention only the fine Romanesque church of Leuchars; the ruined abbeys of Balmerino and Lindores; Magus Muir, the scene of Sharp's murder; Cultra, the birthplace of Wilkie; and Balcarras, of Lady Ann Barnard. Fife, excluding two groups of burghs, returns two members to parliament. It is sixteenth in size among Scottish counties. Pop. (1801) 93,743; (1841) 140,140; (1881) 171,931; (1911) 267,739; (1921) 292,902; mainly in the 28 burghs. See the history by Sir

Robert Sibbald (1710); Æ. J. G. Mackay, *History of Fife and Kinross* (1890 and 1896); A. H. Millar, *Fife Pictorial and Historical* (2 vols. 1895); E. S. Valentine, *Fifeshire* (1910); J. Wilkie, *History of Fife* (1925).—The county has since 1759 given the title of Earl to the family of Duff. The sixth earl (1849–1912) married in 1889 the Princess Louise, and became Marquis of Macduff and Duke of Fife.

Fifth-monarchy Men, an extreme sect of the time of the Puritan revolution, strongly represented in Cromwell's army, who looked on the establishment of his power as the commencement of a new reign of Christ on earth, in succession to the four great monarchies of Antichrist marked out by the prophet Daniel. Cromwell crushed their rebellious intrigues with his soldiers and their plot to murder himself, and in 1657 flung their leaders, Venner, Grey, and Hopkins, into prison. In 1661 Venner headed another rising, for which he and sixteen others were executed.

See Louise Fargo Brown, *The Political Activities of the Baptists and Fifth-Monarchy Men* (1913).

Fig (*Ficus*), a genus of trees and shrubs belonging to the order (or sub-order of Urticaceæ) Moraceæ, characterised by the remarkable inflorescence in which that normal checking of the flowering axis which reduces the elongated spike to the flat capitulum has gone so far as to render this positively concave, the apex thus coming to be at the bottom of a cup (see INFLORESCENCE). This axis almost closes upon the small internal flowers, save for a small opening at the apex, and becomes succulent and fruit-like. It is always monœcious or dicecious. The male flowers, which in the monœcious species develop round the opening of the fig, have three or five stamens, and the female, which arise on the sides and bottom, a bilobed stigma, but the ovary contains only a single seed, which becomes stony. For fertilisation, see CAPRIFICATION, and FLOWERS. There are about 600 species, some of them very large trees. Almost all belong to tropical and subtropical countries, of the vegetation of which they often form a most important feature. They abound in India, in every jungle and hilly situation, to the most northern Himalaya, and some of them are cultivated about every village. Both *F. religiosa* (the Peepul) and *F. Rumphii* are held in veneration by the Hindus. The most notable species are the Common Fig (see below); the Banyan (q.v.); the Peepul (q.v.); Bo Tree, or Sacred Fig of India, the Sycamore (q.v.); and the India-rubber Fig (*F. elastica*). See INDIA-RUBBER. The leaves of some species are entire, those of others are lobed. Several species of fig exhibit the character, for which the banyan in particular has become celebrated, of sending roots straight down to the ground from their spreading branches, and thus multiplying the apparent stems, by which a vast canopy of branches and foliage is supported. The East Indian Caoutchouc or India-rubber Tree is remarkable for the exposure of its main roots, which rise in masses above ground, extending on all sides from the base like great writhing snakes. Some figs are creeping or trailing shrubs, with slender stems, covering heaps of stones, or ascending trees like ivy. Besides the common fig, many species yield edible fruits, although none of them are nearly equal to it in value. The milky juice of several species is bland and abundant, as of *F. Saussureana*, which has therefore been ranked among Cow-trees. In other species the milky juice is very acrid. That of the common fig produces a burning sensation on the tongue. That of *F. toxicaria*, a native of the Malayan islands, is used for poisoning arrows. Lac (q.v.) is gathered from some species. The leaves of *F. politoria* are so rough that they are used for polishing wood and

ivory in India. The juice of the fruit of *F. tinctoria* is used in Tahiti to dye cloth: the colour is at first green, but being acted on by the juice of a *Cordia* it becomes bright red. The bark supplies cordage, of which fishing-nets are made.

The Common Fig (*Ficus carica*) is a native of the East, as the specific name (from *Caria*) imports; but it is now cultivated throughout the whole of the south of Europe, and is even found naturalised there. Its cultivation has also extended to many warm countries. In North America it is seldom to be seen farther north than Philadelphia; and it is not sufficiently hardy to be a common fruit-tree in Britain, although even in Scotland figs

Common Fig (*Ficus carica*):
a, fruit; b, section of fruit.

may occasionally be seen ripened on a wall; and in the south of England fig-trees are sometimes grown as standards, and a few small fig orchards exist. It seems to have been grown in England by the Romans, but was not reintroduced until 1525, when Cardinal Pole brought several trees to Lambeth from Italy. Protection is given in some way during winter. Near Paris, and in some other parts of the continent of Europe, fig-trees are so trained that the branches can be tied in bundles and laid along the ground, when they are covered with litter and earth, or, as in the case of the celebrated fig-tree of Roscoff (Finistère), the branches are trained over a vast area of pillared framework. The fig is a low deciduous tree or shrub (15–25 feet), with large, deeply-lobed leaves, which are rough above and downy beneath. The branches are clothed with short hairs, and the bark is greenish. The fruit is produced singly in the axils of the leaves, is pear-shaped, and has a very short stalk; the colour in some varieties is bluish-black; in others, red, purple, yellow, green, or white. The varieties in cultivation are numerous. In warm climates the fig yields two crops in the year—one from the older wood (midsummer shoots of the preceding year), and a second from the young wood (spring shoots of the same year); but in colder regions the latter never comes to perfection. Fig-trees are propagated by seed, by suckers, &c.; very frequently by layers or by cuttings. In Britain they are often to be seen in greenhouses, and grow well in pots. If the soil of the open border is too rich, root pruning must be adopted, although liquid manure may be given while the figs are swelling. Figs may be eaten 'green' (i.e. ripe) or dried, and the latter form an important article of food in the Levant; in more northern regions they are used for dessert, or for medicinal purposes, being applied to gumboils and other sores, and also administered

in pulmonary and nephritic affections, and to relieve habitual constipation. The pulp contains about 62 per cent. of grape-sugar. Figs are either dried in the sun or in ovens built for the purpose. Great quantities are annually imported into Britain from the Mediterranean. The best are mostly brought from Smyrna. Greece and various parts of Italy also export figs. The finest kinds are tightly packed in boxes; others are crowded into sacks of matting, or strung, by a hole in the middle, on strings of bast. In the Levant, Portugal, and the Canaries a spirit is distilled from fermented figs. In some places figs roasted and ground are used to produce the so-called fig-coffee; the excellence of the Vienna coffee is sometimes attributed to an admixture of ground figs.

The fig has been reckoned among the most valuable fruits since the earliest times; thus, it is mentioned with corn, wine, and oil as one of the leading riches of the promised land. The Athenians, too, seem to have largely subsisted upon figs, especially before the culture of cereals became general; and a fig-tree was the device of the city. It appears that special officers were appointed to denounce illicit export or engrossing of figs, the 'sycophants,' whose title came to acquire such different meaning. The word, however, in this sense is not found in any ancient author. See Solms-Laubach, *Domestikation des Gewöhnlichen Feigenbaums* (1882); Ravasini, *Die Feigenbäume Italiens* (1911); Bicknell, *The Common Fig-tree* (1912).

Figaro, a dramatic character introduced on the Parisian stage in 1775 by Beaumarchais (q.v.) in his *Barbier de Séville* and his *Mariage de Figaro*, is first a barber and then a valet-de-chambre, and has become a type of cunning, intrigue, and dexterity. Mozart and Rossini made Beaumarchais's plays the basis of classic operas. The name has been adopted by a well-known Parisian newspaper (founded 1854).

Figéac, a town in the French department of Lot, is situated in a valley surrounded by finely wooded hills, 32 miles ENE. of Cahors. Irregularly built, with a medieval aspect, it possesses two beautiful Gothic churches, and owes its origin to a Benedictine monastery founded by Pepin the Short in 755. Figéac has cotton manufactures, dye-works, and a trade in cattle. Pop. 5500.

Fighting-fish (*Betta pugnax*), a small freshwater fish, especially at home in Siam, where it is reared on account of its curious pugnacity. It belongs to the family Labyrinthici, which includes other interesting fishes, such as the Climbing Perch (*Anabas*), the beautiful Paradise-fish, the well-flavoured Gourami. When two fighting-fish are brought together they often rush immediately to combat; or it is even enough to introduce a looking-glass into the water, when the fish hastens to attack its own image. Fish-fights are a favourite amusement of the Siamese; the license to exhibit them yields a considerable annual revenue; and an extraordinary amount of gambling takes place in connection with them—not merely money and property, but children and liberty being sometimes staked. When the fish is quiet its colours are dull; but when it is excited they glow with metallic splendour, and its projected gill-membrane waves like a black frill round its throat.

Figig, or FIGUIG, an oasis 6 miles square in the south-east of Morocco, occupied by Fiance in 1893. There are some 12,000 inhabitants in seven villages, mainly Berber in origin, who recognised only a shadowy suzerainty in Morocco.

Figueira da Foz, a Portuguese watering-place, 23 miles W. by S. of Coimbra; pop. 40,000.

Figueras, a town in the north-east of Spain, 25 miles N. of Gerona, with a few manu-

factories. Overlooking the town is the strong frontier fortress of San Fernando, constructed by Ferdinand VI. In the vicinity of the town are gold and copper mines. On three occasions (1794, 1808, 1823) Figueras has been taken by the French. Pop. 13,000.

Figueras, ESTANISLAO, a Spanish statesman, was born at Barcelona, 13th November 1819. Although he joined the republican party in 1840, he was not elected to the Cortes until 1850. For taking part in republican plots in 1866 he was in the following year cast into prison; but after the expulsion of Queen Isabella he became a member of the republican committee of government. Finally the abdication of King Amadeus, in 1873, opened the way for Figueras, and he became president of the Spanish republic; but, owing to differences with his colleagues in power, he was constrained to resign office after only about four months' exercise of authority. Retiring from public life, he died at Madrid on 11th November 1882.

Figuiet, LOUIS, writer, was born at Montpellier, 15th February 1819. His first appointment as professor was at the Montpellier school of pharmacy in 1846; seven years later he removed to Paris to occupy a similar post there. Amongst his books are several on the wonders, inventions, and discoveries of modern science and modern industry, a volume on alchemy, and one in defence of the immortality of the soul. Many of these have been translated into English (*The Ocean World, The World before the Deluge, The Day after Death, The Vegetable World, Reptiles and Birds*, &c.). From 1856 he edited an annual, *L'Année Scientifique et Industrielle*. He died 8th November 1894.—His wife, JULIETTE BOUSCAREN (1829–79), also made a name for herself by novels and interesting sketches.

Figurate Numbers. The nature of figurate numbers will be understood from the following table:

	1,	2,	3,	4,	5,	6,	7,	&c.
I.	1,	3,	6,	10,	15,	21,	28,	&c.
II.	1,	4,	10,	20,	35,	56,	84,	&c.
III.	1,	5,	15,	35,	70,	126,	210,	&c.
	&c.			&c.				

The natural numbers are here taken as the basis, and the first order of figurate numbers is formed from the series by successive additions; thus, the fifth number of the first order is the sum of the first five natural numbers. The second order is then formed from the first in the same way; and so on. If instead of the series of natural numbers whose difference is 1, we take the series whose differences are 2, 3, 4, &c., we may form as many different sets of figurate numbers. The name *figurate* is derived from the circumstance that the simpler of them may be represented by arrangements of equally distant points, forming geometrical figures. The numbers belonging to the first orders receive the general name of *polygonal*, and the special names of *triangular*, *square*, *pentagonal*, &c., according as the difference of the basis is 1, 2, 3, &c. Those of the second orders are called *pyramidal* numbers, and according to the difference of the basis are *triagonally*, *quadrangonally*, or *pentagonally pyramidal*. The polygonal numbers may be represented by points on a surface; the pyramidal by piles of balls.

Figure, in Music. See MOTIF; for Figured Bass, see ACCOMPANIMENT.

Figure-head, the ornamental figure or bust on the head of a ship, immediately under the bowsprit. Where the vessel's name cannot be represented by such a figure, a piece of timber, finished off in the form of a volute or scroll, often takes its

place on sailing-ships; on steamships the bow is usually plain. The huge figure-heads of several historical old line-of-battle ships are still carefully preserved at Millwall, including that of the 'fighting Téméraire.'

Figure-stone. See STEATITE.

Figwort, a name sometimes applied to *Scrophularia nodosa* (see SCROPHULARIA), and sometimes to *Ranunculus Ficaria*, the lesser Celandine (see CELANDINE).

Fiji. The Fiji or Viti Islands are a British dependency in the South Pacific Ocean, situated in 15°–22° S. lat. and 176° E.—178° W. long. Their nearest neighbours are the Tonga or Friendly Islands, between 200 and 300 miles to the south-east; they are about 700 miles from the French colony of New Caledonia, 1100 miles from Auckland in New Zealand, 1700 from Sydney in New South Wales, 1800 from Tahiti, and 4700 from the great American port of San Francisco. They have regular communication with Auckland, Sydney, Tonga, Honolulu, and Vancouver. The island of Rotumah (discovered 1793), about 250 miles distant, a little to the west of north, has been since 1881 included in the colony.

The islands were sighted in 1643 by Tasman, the great Dutch sailor, whose name is borne by Tasmania. Turtle Island (or Vatoa), in the extreme south-east of the group, was discovered and so named by Captain Cook in 1774; but, like most of the South Sea islands, the Fiji Archipelago was little known before the 19th century. Since that date its history has been the not uncommon one of native dissensions, gradual European intrusion, and finally European protection. In 1804 some escaped prisoners from Australia are said to have settled in the islands. In 1835 Wesleyan missionaries first came over from Tonga to begin their wonderful work of conversion to Christianity; and trade, which had begun with dealings in such articles as beche de mer and sandalwood, gradually led to a small white settlement.

In 1849 some damage was done to the property of the American consul; a heavy claim was in consequence preferred by the United States government against the leading chief Thakombau, which he was wholly unable to meet, and in 1853 he offered the sovereignty of the islands to Great Britain, on condition that he retained his rank and that his debt was paid. As a set-off to the payment he offered to make over, if required, to the British government the ownership in fee simple of 200,000 acres of land. Upon receipt of this offer a special commissioner, Colonel Smythe, was sent to Fiji, charged to report especially upon its prospective advantages as a naval and coaling station and as a place for cotton-growing. On his advice the offer of sovereignty was in 1862 rejected. The following years brought a considerable increase to the white population of the islands, cotton-planting being stimulated by the American civil war. About 1868 a company was formed in Australia, under the name of the Polynesia Company, to take over Thakombau's debt, and with it the 200,000 acres referred to above. In 1871 a kind of constitutional government was set up by the European advisers of King Thakombau, but the cession of the islands to Great Britain was again pressed on, and, after further inquiry in 1873, Sir Hercules Robinson, then governor of New South Wales, was sent to Fiji, and on the 10th of October 1874 formally accepted the sovereignty of the group on behalf of the British crown.

Fiji was constituted and remains a crown colony, with governor, who is also High Commissioner for the Western Pacific, an executive council of official and unofficial nominated members, and a legislative

council comprising the governor, not more than twelve nominated members (one Indian), seven elected members, and two native members. The natives have village, district, and provincial councils (there being seventeen provinces), and a special system of taxes, paid mainly in kind.

The islands, from 200 to 250 in number, lie in a ring, open on the southern side in a manner resembling the West Indies. On the west and north are the two large islands of Viti Levu and Vanua Levu, with a group of small islands and reefs outside them; and on the east there is a long string of islands of small size, answering to the Leeward and Windward groups in the West Indies.

The total area of the colony (including Rotumah) is given at 7083 sq. m., being about the same size as Wales. The area of Viti Levu is over 4000 sq. m., rather smaller than Jamaica, and the area of Vanua Levu is about 2100 sq. m. Since 1882 the capital of the colony has been Suva, on the south coast of Viti Levu, where there is a fine harbour; before that date Levuka, on the little island of Ovalau, off the east coast of Viti Levu, also possessing a good harbour, was the European capital. Municipalities have been established at both places.

The Fiji Islands are of volcanic formation, the shape of the mountains (the highest of which rise to some 4500 feet) and the existence of hot springs testifying to volcanic agency; and they are surrounded by coral reefs, which act as natural breakwaters. They are singularly favoured by nature, being well supplied with harbours, and equally well

The population of Fiji in 1921 amounted to 154,584, of whom some 3800 were Europeans, over 84,000 native Fijians, and over 60,000 Indians. The native population was larger in former years, and was much reduced by an outbreak of measles in 1875. The death-rate among the natives is high, being about twice the rate for England. They are in race akin to the Papuans, being the easternmost members of that family, but an admixture of the lighter Polynesians has been brought in from Tonga and elsewhere, and has, especially in the eastern islands of the group, leavened the native Melanesian breed. In language and polity the natives of Rotumah differ entirely from the Fijians. The Fijians were, prior to the introduction of Christianity, notoriously ferocious cannibals, but religious after their kind, and possessing a strong belief in a future life. At the present time the Christian religion (Roman Catholic and Wesleyan) is almost universal in the islands. Education is carried on in government schools and in mission schools, which on complying with certain conditions are entitled to government aid. Of government schools the chief are at Suva (one for boys, one for girls), Levuka, and Rarawai. The Queen Victoria Memorial School at Nasinu, also state aided, is for the higher education of natives. The revenue, derived mainly from customs duties and native taxation, has not always covered the expenditure. Sugar is far the most important export, though a scarcity of labour and an acute economic unrest, the outcome of the ending, in 1916, of the importation of Indian contract workers, and of the

cancellation, in 1920, of all the indentures of Indian labourers, have greatly hampered the industry's growth. Next in importance as exports come copra and fruit, especially bananas and pineapples. Rubber is also an established industry. Drapery, machinery, hardware, coal, breadstuffs, meats, and rice are the principal imports. Goods are imported mainly from Australia, while the bulk of Fijian produce goes to New Zealand. There are no railways in Fiji, but the tram-lines of the sugar plantations are sometimes open to public use. Fiji has become British by the force of circumstances, and not on account of its natural advantages; but it has considerable agricultural resources, and is a station from which British influence can be exercised in the South Pacific. In 1920 a prolonged strike of Indian labourers culminated

in rioting, which was quelled by show of naval and military force from Australia and New Zealand.

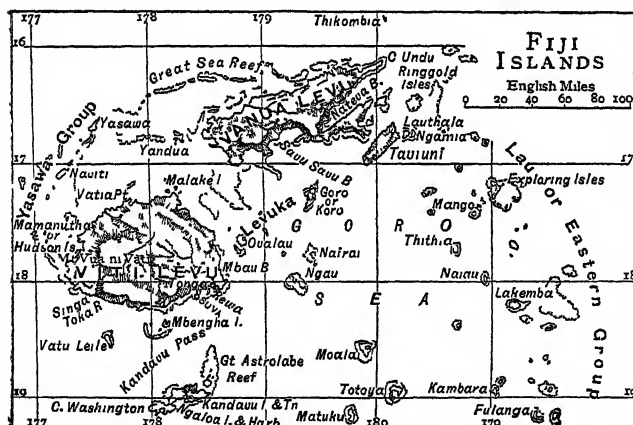

See parliamentary report of 1862 and the annual Colonial Office List; also C. F. Gordon Cumming, *At Home in Fiji* (1882); B. Thomson, *Fiji for Tourists* (1897), and *The Fijians* (1908); W. A. Chapple, *Fiji* (1921); W. Deane, *Fijian Society* (1921); and A. B. Brewster, *The Hill Tribes of Fiji* (1922).

Filament, in Botany, is the stalk of the stamen which supports the pollen-containing *anther*, and stands to the anther as the petiole to the leaf-blade. See FLOWER, LEAF, STAMEN.

Filaria, Filariasis. See the articles GUINEA-WORM, ELEPHANTIASIS ARABUM.

Filbert. See HAZEL.

Fildes, SIR LUKE, figure-painter, was born at Liverpool in 1844. He studied in the South Kensington Schools and in the Royal Academy, and became known first of all as a woodcut designer, contributing to *Once-a-Week*, *Cornhill*,

with rivers, having an abundant water-supply, a rich soil, and a climate which, though tropical and somewhat enervating to Europeans (who are subject to dysentery), is not unhealthy or extreme. They suffer, however, from the ravages of hurricanes, and earthquakes occasionally occur. The temperature varies from about 60°–90°, November to April being the warm season. The rainfall, abundant in the warm season, is greatest and the land is most heavily timbered on the south-eastern—the windward—side of the islands; on the leeward side the face of the country is more that of open grass-land. With the exception of the bêche-de-mer and pearl-shell industries, the resources of Fiji are almost purely agricultural. In addition to timber and fruit-trees, and coconut palms, the vegetable products of the islands include sugar, grown with the help of imported Indian and Polynesian labour, rubber, maize, cotton, tea, and coffee. There are hardly any indigenous mammals. Iron in considerable quantities, and traces of gold, silver, tin, antimony, manganese, &c., are found, but none of these minerals are worked.

and *The Graphic*, and illustrating Dickens's *Edwin Drood*. He began to exhibit in the Academy in 1868, with his 'Nightfall,' and in 1874 produced a very popular picture, 'Applicants for Admission to a Casual Ward'—originally a *Graphic* woodcut—followed in 1877 by the powerful 'Widower,' and in 1892 by 'The Doctor.' Other subjects have been portraits and figure-pictures of Venetian life, in which he has developed a stronger colour-sense than his earlier works gave any indication of. He was elected an A.R.A. in 1879, R.A. in 1887, knighted in 1906, and made K.C.V.O. in 1918. See D. C. Thomson in *Art Annual* (1895).

File, a steel tool, having its surface covered with teeth, and used for smoothing and shaping metals, &c. Files are classified and named according to their shape, size, and fineness of cut, and the purpose for which they are made. Thus, in shape they may be flat, square, round or *rat-tail*, triangular, half-round, feather-edged, &c., besides being variously bent, in order to get at intricate work. Most files are made thicker in the middle, or 'bellied,' a form which best suits the hands in the act of filing. Files generally are made of the best crucible steel, the forged and shaped blanks when ready for cutting being held upon an anvil by means of a long loop of leather-strap, into which the cutter places his foot. The face of the anvil is covered with a flat piece of pewter, the softness of which preserves the teeth on one side of the file when those on the opposite face are being struck. The cutter forms the teeth by striking with a hammer a short, stout chisel, held obliquely at an angle of about 12° or 14° from the perpendicular. If the chisel were perpendicular, a furrow like the letter V would be indented, and an equal burr struck up on each side; but as a cutting tooth somewhat like that of a saw is required, this is effected by the oblique stroke of the chisel, by which a burr is thrown up on one side only—viz. towards the tang. The cutting is commenced at the point of the file; the chisel is then drawn backwards, laid upon the blank, and slid forwards till it reaches the burr raised by the last cut; the blow is now struck, and another tooth and burr produced, which serves as a guide for the next cut; and so on. The distance between the teeth thus depends on the force of the blow and the obliquity of the cut; for the heavier the blow, the greater the ridge or burr, and the obliquity determines the distance of the cut from the burr. The skill of the workman consists, therefore, in the precise regulation of the blows.

Files are either single cut—i.e. made with a single series of parallel cuts—or, more commonly, double cut—i.e. they have two series or *courses* of chisel-cuts, which are oppositely inclined at an angle of about 55° to the central line of the file. The second course is made in the same manner as the first, but with lighter blows, and is usually somewhat finer than the first. This angular crossing converts the ridges into pointed teeth. Files used for soft metals which are liable to clog the teeth are single cut—i.e. they have but one course of cuts. Taper files have the teeth finer towards the point. Rasps for wood or horn, &c. are cut with triangular punches, each tooth being an angular pit with a strong burr, instead of a long furrow. The rapidity with which the blows are struck varies with the fineness of the file: sixty or eighty cuts are commonly made per minute. Classified according to fineness of cut, files are known as rough, bastard, smooth, and superfine. A superfine file of small size may have as many as 216 cuts per inch, while a large rough file may have not more than twenty-one cuts to the inch. The sharpness and abrading effect of files is greatly

improved by subjecting them after cutting to a sand-blast, whereby a slight recurvature of the burr, which is always present as the file leaves the cutter, is corrected, and the edge is rendered very keen.

Files have to be very carefully hardened and tempered. If heated too strongly, or made too hard, the steel is so brittle that the teeth tear off; if too soft, they wear down rapidly, and the file soon becomes useless. Great care is also required in keeping them straight, as the sudden cooling necessary for hardening is very apt to warp the steel.

Files are also cut by machinery, but attempts long met with only partial success; the chief difficulty arises from the necessity of modifying the force of the blow to suit the hardness of the steel. It is practically impossible to supply a large number of blanks all of exactly the same hardness; and if the machine be adjusted to suit the hardness of one blank, it may strike too heavy or too light a blow for the next; whereas the workman *feels* at once the hardness of the steel he is working upon, and adjusts his blows accordingly.

File (Fr. *file*, 'a row,' from Lat. *filum*; Ital. *fila*, *filò*), in a military sense, is used to signify any line of men standing directly behind each other, as rank refers to men standing beside one another. In ordinary two-deep formations, a file consists of two men, one in the front rank and one in the rear rank. *Single-file* formation signifies one man from a single rank followed by the men on his right (or left) in succession. *Rank and file* is a term often used to mean the private soldiers of a regiment only, but it really includes also the corporals, who are therefore sometimes called rank and file non-commissioned officers.

File-fish. See BALISTES.

Filey, a rising watering-place on the east coast of Yorkshire, 9 miles SE. of Scarborough by rail, occupies a picturesque site on cliffs overlooking Filey Bay. It has a spa, an ancient cruciform church, a safe harbour protected by Flamborough Head, and a sea-wall and promenade. Pop. 4500.

Filiation. See AFFILIATION.

Filibusters (Span. *filibustero*, apparently derived through the Fr. *filibustier*, formerly *fridustier*, from the Dutch *vrijbuitter*, 'freebooter'; possibly influenced in form by English *flyboat*, Dutch *vlieboot*, Fr. *flibot*, Sp. *fibote*, a fast sailing vessel of not more than 100 tons), originally another name for Buccaneers (q.v.). Later the term came to be applied to those adventurers who, between 1850 and 1860, organised expeditions from the United States in violation of international law, for the purpose of revolutionising certain states in Central America and the Spanish West Indies. The most noted was William Walker (q.v.). See Roche's *Story of the Filibusters* (1891). The term is now general, signifying persons engaging in unauthorised and irregular warfare, while in the United States the word also means an obstructionist in Congress.

Filicaia, VINCENZO, lyrical poet, was born at Florence, 30th December 1642. The publication of his six odes celebrating the deliverance of Vienna in 1683 by John Sobieski from the besieging forces of the Turks attracted the notice of Queen Christina of Sweden, who relieved him from harassing pecuniary embarrassments. Ultimately he obtained a post from the Grand-duke of Tuscany, and he died at Florence, 25th September 1707. Some of his patriotic sonnets are famous; but his verse, though not without beauty and spirit, is disfigured by the rhetorical tricks and false conceits of the period. An edition of his works appeared at Florence in 1864.

Filices. See FERNS.

Filigree (through Span. from Lat. *filum*, 'a thread,' and *granum*, 'a grain'), so called because composed of fine wire of silver or gold, often ornamented with small beads. The wire used is twisted into spirals and other convoluted forms, which are united and partly consolidated by soldering; and these spirals, &c. are combined to form a sort of metallic lace-work, which is shaped into brooches, ear-rings, crosses, head-ornaments, card-cases, trays, and other objects of a light and elegant character. Filigree-work is also employed for the ornamentation of articles having a solid metallic base of precious metal, or of copper, the wires being soldered down in definite patterns to the supporting plate. That filigree, as a style of jeweller's work, is of great antiquity is evidenced by remains found in ancient Egyptian tombs. That a knowledge of the art was very widespread is also manifest from the fact that it was largely practised by the ancient Greeks, the Etruscans, and the Romans. We know further that from remote ages it was practised in Central Asia and in India, where to this day it has continued in unbroken succession, and it is now a most characteristic style of work in the Central and the United Provinces. Among the Celtic and Scandinavian tribes of early times filigree was also a favourite method of ornamentation. The Quigrich (see FILLAN, ST), and the Hunterston Brooch (see BROOCH) are magnificent examples of early northern metal-work in which filigree ornamentation on a solid basis is a prominent feature. In the jewelry of the Scandinavian races filigree still occupies an important place. The manufacture of filigree jewelry is so characteristic of Malta that the style has come to be popularly known as Maltese work.

Filioque. See CREEDS.

Fillan, ST, was the son of Feredach, a prince of Munster, and of St Kentigerna, who in 734 died on Inchcailloch in Loch Lomond. He succeeded St Mund as abbot of the monastery on the Holy Loch, but presently withdrew to Upper Glendochart (Strathfillan), 3 miles SSE. of Tyndrum, where he died on 9th January 777. In 1318 Robert Bruce re-established here an Augustinian priory; and here too was the 'holy pool of Fillan,' in which, not a century since, sick people bathed, and lunatics were plunged. The latter were afterwards left all night, bound hand and foot, in a stone coffin; and if in the morning the knots were

untied there was hope of recovery. Two relics of the saint have, after strange wanderings, been reunited at Edinburgh in the Antiquarian Museum. One, his square-shaped bell of cast bronze, 12 inches high, lay in the churchyard, and was employed in that lunatic 'rope-trick,' till in 1798 an English tourist bore it off to Hertfordshire, whence in 1869 it was recovered through Bishop Forbes of Brechin. The other relic is the Quigrich (Gael. *coygerach*, 'stranger')—the bronze head of a pastoral staff (fig. 1), adorned with niello, and inclosed in a beautiful outer case of silver (fig. 2), 9 inches high, gilt, and ornamented with chased work and filigree. Both are undoubtedly of Celtic workmanship; but the case is naturally the later of the two, and seems partly assignable to the 14th and 15th centuries. Possessed of both thieving

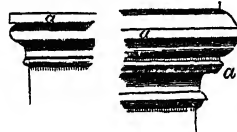

finding and healing properties, the Quigrich from Bruce's time and earlier was in the hereditary custody of a family named Jore, Doire, or Dewar, who enjoyed certain privileges therefor. James III.'s charter of confirmation (1487) to Malice Doire was presented for registration among the public records of Scotland so recently as 1734. In 1818 the Dewars emigrated from Balquhider to Ontario, taking with them the Quigrich, which in 1876 was, through Dr Daniel

Fig. 2.—Silver Case of the Quigrich: Wilson, bought for £100 by the Scottish Society of Antiquaries.

St Fillan, at the foot of Loch Earn, is associated with an earlier saint, called *an Iobar*, 'the leper,' whose feast fell on 20th June. See Dr John Stuart's 'Historical Notices of St Fillan's Crozier,' in *Proc. Soc. Ant. Scot.* (xii. 1877), and Dr Joseph Anderson's *Scotland in Early Christian Times* (i. 1881).

Fillet, in Architecture, a small space or band, like a narrow ribbon, used along with mouldings.

a, a, a (see fig.) are examples of fillets, both in classic and Gothic architecture.

Fillmore, MILLARD, thirteenth president of the United States, was born on 7th February

1800, at Summer Hill, New York, where his education was limited to the very imperfect instruction furnished during three months of the year by a primitive frontier school. At the age of fourteen he was bound apprentice to a wool-carder; and during the five years he laboured at this occupation he used every means at his disposal to cultivate his mind. In 1819 he began the study of law, receiving his board in return for his work in the office of a country lawyer; and during part of this time he also taught school, until in 1823 he was admitted to the Buffalo bar, where he built up a solid reputation for sound legal knowledge and sterling probity. In 1828 he began his political career, being in that year returned by Erie county to the state legislature of New York, where he joined the Whig party, and was mainly instrumental in procuring the abolition of imprisonment for debt in the state of New York. In the period 1832-42 he was four times elected member of congress; in 1844 he was defeated in a contest for the governorship of the state; in 1847 he was elected to the post of comptroller of New York; and in the following year he was made vice-president of the United States. The unexpected death of President Taylor in July 1850 left the chief magistracy vacant, and Fillmore succeeded to that office, which he held till 1853. He proved an able statesman, and his presidency was marked by the passing of some very salutary measures, notwithstanding that his party were in the minority; but his signing of and attempt to enforce the fugitive-slave law rendered him unpopular in the North. In 1856 he was nominated for the presidency by the American party, but the struggle lay be-

tween the republican and the democratic candidates, and he received the electoral vote of Maryland only. He visited Europe in 1855 and 1866. He took no active part in the civil war, although he gave his influence to the cause of the Union. After his retirement from political life he resided at Buffalo, where he died 7th March 1874. See Chamberlain's *Biography of Fillmore* (1856); Buffalo Historical Society's publications, vols. x.-xi. (1907); Life by Griffiths (1915).

Filmer, SIR ROBERT, an extreme advocate of the theory of the divine right of kings, was born at East Sutton in Kent, in the end of the 16th century. He matriculated at Cambridge in 1604, and died 26th May 1653. The germ of his theory is the proposition that the father of a family is the divinely ordained type of a ruler, and that his power is absolute. Accordingly, Filmer taught, a king's acts should be subject to no check or control whatsoever; his will is the only right source of law. Hence he is not in any sense answerable to his subjects for his doings; for them either to depose him or even to criticise his conduct is criminal and immoral. These views are expounded with most fullness in his *Patriarcha*, published in 1680 after his death, and were critically examined in Locke's *Treatise on Government*. Filmer's *Freeholder's Grand Inquest* (1648) is an exposition of his ideas as to the relations that ought to obtain between the king and the houses of parliament. See DIVINE RIGHT.

Filmy Ferns (*Hymenophyllaceæ*), an order of Ferns (q.v.), including only two (or three) genera, but over two hundred species. They grow in large, spreading, mossy masses on rocks and tree-stems in moist places, are chiefly tropical, rare in the southern hemisphere, still rarer in the northern. A British species of the large genus *Hymenophyllum* (*H. tunbridgense*), despite its apparently local name, is one of the most widely distributed of plants, being found not only over Europe, but in South America, at the Cape, and in New Zealand. *Trichomanes* has ninety species, mostly tropical, only one ranging as far as southern Europe. Although chiefly distinguished by systematists on account of the minute structure of their sporangia, they are more remarkable for the exceptionally simple structure of their moss-like leaves, which consist usually of only a single layer of uniform parenchymatous cells. More rarely several layers are present, but there is never a distinct epidermis; moreover, as the plants grow in very wet places—often, for instance, in the spray of waterfalls—and as the leaves are so hygroscopic as to be constantly saturated, even when not absolutely covered with moisture, the usual air-spaces, and with them the stomata of ordinary leaves, are not developed. From this saturation with water instead of air the thin, wet, filmy foliage is thus peculiarly transparent, and so seems singularly dark-green by reflected light. To the exceptional yet beautiful appearance thus accounted for their interest to fern-growers is due.

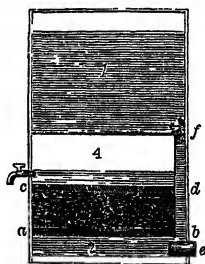

Filter. When solid matter is suspended in a liquid in which it is insoluble, it may be separated by various means (see CLARIFICATION), one of which is filtration. The process of filtration consists in passing the liquid through some porous substance, the interstices of which are too small to admit of the passage of the solid particles, the principle of the action being the same as that of a sieve. One of the simplest forms of filter is that commonly used in chemical laboratories for separating precipitates, &c. A square or circular piece of blotting-paper is folded in four, the corner where the four folds meet is placed downwards in a

funnel, and one side is partly opened, so that the paper forms a lining to the funnel. The liquid passes through the pores of the paper, and the solid matter rests upon it. The chief advantages of this filter are its simplicity and the ease with which the solid matter may be removed and examined.

A simple water-filter for domestic purposes is sometimes made by stuffing a piece of sponge in the bottom of a funnel or the hole of a flower-pot, and then placing above this a layer of pebbles, then a layer of coarse sand, and above this a layer of pounded charcoal three or four inches in depth. Another layer of pebbles should be placed above the charcoal, to prevent it from being stirred up when the water is poured in. It is obvious that such a filter will require occasional cleaning, and renewal of the charcoal. By a small addition to this a cottage-filter may be made which, for practical use, is quite equal to the most expensive filters of corresponding size. It consists of two flower-pots, one above the other; the lower one is fitted with the sponge and filtering layers above described, and the upper one with a sponge only. The upper pot should be the larger, and, if the lower one is strong, the upper one may stand in it. The two pots thus arranged are placed upon a three-legged stool with a hole in it, through which the projecting part of the lower sponge passes, and the water drops into a jug placed below. The upper pot serves as a reservoir, its sponge stops the coarser impurities, and thus the filtering layers of the lower one may be used for a long period without being renewed, if the upper sponge be occasionally cleaned. Care must be taken to wedge the upper sponge tightly enough, to prevent the water passing from the upper pot more rapidly than it can filter through the lower one.

A great variety of filters are made on a similar principle to the above, but constructed of ornamental earthenware or porcelain vessels of suitable shape. In purchasing a filter, the buyer must not be satisfied with merely seeing that the water which has passed through it is rendered perfectly transparent—this is so easily done by a new and clean filter—but he should see that the filter is so constructed as to admit of being readily cleansed, for the residual matter must lodge somewhere, and must be somehow removed. When large quantities of water have to be filtered this becomes a serious

difficulty, and many ingenious modes of overcoming it have been devised. In most of these water is made to *ascend* through the filtering medium, in order that the impurities collected on it may fall back into the impure water. Leloge's ascending filter consists of four compartments, one above the other; the upper part, containing the impure water, is equal in capacity to the other three. This

Leloge's Filter:

1, 2, 3, 4, the four compartments; *ab*, the first porous stone of third or filtering compartment; *cd*, the exit filtering stone of 2; *e*, the plug to remove for cleaning out second compartment; *f*, a loose sponge at entrance of communicating tube.

communicates by a tube with the lowest one, which is of small height. The top of this is formed by a piece of porous filtering-stone, through which alone the water can pass into the third compartment, which is filled with charcoal, and covered with another plate of porous stone. The fourth compartment, immediately above the third, receives the filtered water, which has been forced through the lower stone, the charcoal, and the

upper stone. A tap is affixed to this, to draw off the filtered water, and a plug to the second or lowest compartment, to remove the sediment.

A large number of other ascending filters have been patented. Siphon filters are cylindrical pewter vessels, containing the filtering media, to which is attached a long coil of flexible pipe. When used, the cylinder is immersed in the water-butt or cistern, the pipe uncoiled, bent over the edge of the cistern, and brought down considerably below the level of the water. It is then started by applying the mouth to the lower end, and sucking it till the water begins to flow, after which it continues to do so, and keeps up a large supply of clear water. This, of course, is an ascending filter, and the upward pressure is proportionate to the difference between the height of the water in the cistern and that of the lower end of the exit tube (see SIPHON). Filtering on a large scale is effected by using several tanks or reservoirs, in the first of which is coarse material such as gravel, the water passing from this to a second, and from there through a finer filter to the main receptacle, where the filtered water is stored and drawn off for use.

Various means of compressing carbon into solid porous masses have been patented, and filters are made in which the water passes through blocks of this compressed carbon. Most of these are well adapted for the purpose, but their asserted superiority over filters composed of layers of sand and charcoal is doubtful. A very convenient portable filter for soldiers, travellers, and others who may require to drink from turbid ponds and rivers is constructed of Ransome's filtering stone, and is also made of the compressed carbon. A small cylinder of the stone or carbon is connected with a flexible india-rubber tube in such a manner that the cylinder may be immersed in a river, the mouth applied to a mouthpiece at the other end of the tube, and the water drawn through the filtering-cylinder.

It has been questioned whether soluble matter, such as common salt, is in any degree removed from water by filtration. Theoretically it was assumed that this is impossible, since the filter only acts mechanically in stopping suspended particles; but the results of experiments show that from 5 per cent. of soluble salts may be separated by sand-filters such as above described. Another most important matter is to ascertain to what extent soluble organic matter may be decomposed by filtration, especially by charcoal filters, and to ascertain how long charcoal and other porous matter retains its property of acting on organic matter in watery solution (see CHARCOAL). This is of the highest importance, as it sometimes happens that water of brilliant transparency, and most pleasant to drink, on account of the carbonic acid it contains, is charged with such an amount of poisonous organic matter as to render its use as a daily beverage very dangerous. A filter of animal charcoal will render London porter colourless. Loam and clay have similar properties. The separation from drinking-water of pathogenic microbes (microscopic sources of pestilence) is very difficult, on account of their extreme smallness; but it has been effected by using porous unglazed earthenware as the filtering medium, filtration usually being hastened by putting the apparatus under pressure or by creating a vacuum in the receiving vessel. It is, however, rather troublesome in practice, as pressure is demanded, and the very fine pores are soon clogged. They may be cleansed by raising the filter material to a red heat. A duplicate is therefore required.

When a liquid contains mucilaginous or other matter having viscous properties, there is considerable difficulty in filtering it, as the pores of the medium become filled up and made watertight.

Special filters are therefore required for syrups, oils, &c. Such liquids as ale, beer, &c. would be exceedingly difficult to filter, and therefore they are clarified by the admixture of albumen, gelatin, or some substance with clarifying properties. Oil is usually passed through bags made of horse-hair or twilled cotton cloth (Canton flannel). Syrups are filtered on a small scale by confectioners, &c. by passing them through conical flannel bags, and on a large scale in *creased bag-filters*, made by enclosing a large bag within a smaller one. Thick syrups are clarified with white of egg, and then they may be filtered through a coarse cloth strainer. A recent theory is that the efficiency of filters, so far from depending on the cleanness of the medium, is largely owing to the multitudes of microbes at work in the substance through which the liquor passes. For the treatment of vegetable juices, see BEER, WINE, SUGAR, &c.; and for filtering on the large scale, see SEWAGE, WATER. The simple laboratory filter has to be modified when strong acid or alkaline solutions, &c. require filtration. Pure siliceous sand, a plug of asbestos, pounded glass, or clean charcoal are used for this purpose.

Air Filters.—The extraordinary powers of charcoal in disinfecting the gaseous products evolved from decomposing animal and vegetable matter have been made available in constructing an apparatus for purifying air that is made to pass through it. A suitable cage, containing charcoal in small fragments, is fitted to the opening from which the deleterious gases issue, and is found to render them perfectly inodorous, and probably innocuous. Mechanical impurities suspended in air may be filtered out by forcing the air through a plug of cotton-wool, as in firemen's respirators.

Fimbria, GAIUS FLAVIUS, Roman soldier of the party of Marius, in 86 B.C. encompassed the death of Valerius Flaccus, whose legate he had been. He then made war on Mithridates. By treachery he massacred the people of Ilium, and burned the town. Sulla attacked him in 84, and being deserted by his troops he committed suicide.

Fimbriate, **Fimbriated**, in biology fringed; in heraldry, having a narrow border.

Fin. See FINS.

Final, in the ecclesiastical modes of music, the fundamental note—the modern tonic or keynote.

Finale, the name given to that part of a musical composition which finishes the act of an opera; also to the last movement of an instrumental composition, as in the symphony, quartette, quintette, sonata, &c. The instrumental finale varies greatly in form, from the lively rondos of Haydn to the gigantic vocal finale, in variation form, of Beethoven's 9th Symphony. The operatic finale, as usually understood, is a concerted piece, sometimes extending to a considerable number of different movements, for one, two, or more single voices, with or without chorus. The best type is to be found in Mozart's operas. In Wagner's works there are no finales separable from the preceding parts of the acts; each act is a continuous whole.

Finance. See NATIONAL DEBT, BUDGET, &c.

Finch, a name applied to many Passerine birds included in the family Fringillidæ, but generally used with some prefix, as in the familiar names bullfinch, chaffinch, and goldfinch. A finch is usually small, has a hard conical beak, and generally lives upon seeds. The distribution is almost world-wide, excepting Australia; but the majority inhabit the palearctic region. The Buntings (Emberizidæ) and the Weaver-finches (Ploceidæ) of the Ethiopian and Australian regions are usually kept distinct. The limits of the family Fringillidæ are vague; among the more familiar members are the

Chaffinch (*Fringilla cœlebs*), the Brambling (*F. montifringilla*), the Canary (*Serinus*), the Cross-bills (*Loxia*), the Linnets (*Linota*), and the Sparrows (*Passer*).

Finch, HENEGAGE, first Earl of Nottingham and Lord Chancellor of England, was born in Kent, probably at Eastwell, on 23d December 1621. He was the nephew of Finch, the lord-keeper of Charles I. Educated at Westminster and Christ Church, Oxford, he was called to the bar in 1645. At the Restoration Charles II. made Finch solicitor-general; in this capacity he took an active part in the trial of the regicides, publishing an account of the trial in 1660. In 1670 he became attorney-general, and five years later lord chancellor. As high steward he presided at the impeachment trial of Stafford in 1680. He died in London, 18th December 1682, having gained a high reputation as a graceful orator, and as a lawyer of great integrity, wisdom, and skill. Several of his speeches were published during his lifetime.

Findhorn, a beautiful Scottish river, rising among the Monadhliath Mountains at an altitude of 2800 feet, and running 62 miles north-eastward through the counties of Inverness, Nairn, and Elgin, and past the town of Forres, till it enters the Moray Firth at Findhorn village by a triangular lagoon, 2 miles long by $\frac{2}{3}$ wide. Its waters abound in salmon and trout. Its basin consists of gneiss in the upper part, and of old red sandstone in the lower. At one place it rose nearly 50 feet in the disastrous floods of August 1829, known as the 'Moray Floods.'

Finding of Goods. See LOST PROPERTY.

Findlater, ANDREW, editor of the first edition of this Encyclopædia, was born in December 1810 near Aberdeen, in Aberdeenshire. He was the son of a small farmer, and was bred to farm-work; but he early resolved to go to the university, and in spite of having to do daily a full day's work on the farm, he contrived to qualify himself for entering Aberdeen University. There he graduated in arts, and began theology with a view to becoming a minister; but changing his intention, became a schoolmaster at Tillydesk in the parish of Ellon, and for seven years (1842-49) was head-master of Gordon's Hospital in Aberdeen. After a short residence in Canada, he came in 1853 to Edinburgh to superintend for Messrs W. & R. Chambers a new edition of the *Information for the People* (1857). His next task was the chief work of his life; he devoted himself to the preparation of *Chambers's Encyclopædia*, and ere long was its editor. A scholar of wide and varied learning, equally at home in the physical sciences, in the history of ancient religions, and in modern comparative philology, he turned his acquirements to good account, not merely in directing the Encyclopædia as a whole and fixing its form and scope, but in contributing to it many of its most important articles; and after its completion (1861-68) he superintended a revised issue (1874). He saw through the press a new edition of the *Miscellany* (1869-71) and of the *Etymological Dictionary* (1882); and wrote short but admirable manuals on Astronomy, Language, Physical Geography, and Physiography. In 1864 Aberdeen University gave him its degree of LL.D.; and J. S. Mill, while rector of St Andrews University, made him his assessor in the University Court. Many of the articles in the review columns of the *Scotsman* were from his pen. He was associated with J. S. Mill, Mr Grote, and Professor Bain in editing James Mill's *Analysis of the Phenomena of the Human Mind* (1869); and he counted Thackeray, Littré, and Dr John Brown amongst his friends. His health failing, he withdrew from active work in 1877, and died 1st January 1885.

Findlay, capital of Hancock county, Ohio, 37 miles SW. of Fremont by rail, with foundries, flour and saw mills, &c. Pop. 17,000.

Findon, a village of Kincardineshire, on the coast, 6 miles S. of Aberdeen. *Findon, Finnan*, or smoked haddocks were originally cured not here but on the Findhorn, and were long called *Findrams*.

Finds. See TREASURE-TROVE.

Fine in feudal law was a final agreement between lord and vassal as to the conditions on which lands were to be held by the latter, or between other persons as to rent. The *fine of lands* was a fictitious proceeding formerly in use in order to transfer or secure real property by a mode more efficacious than an ordinary conveyance. The party to whom the land was to be conveyed commenced a fictitious suit against the vendor; and leave being obtained, a covenant was entered into whereby the vendor or defendant recognised the right of the plaintiff to the lands wrongfully kept from him. The fine was registered; and the business was concluded by what was called the *foot of the fine*, setting forth the parties, the time and place, and before whom the fine was levied; the whole was embodied in indentures commencing *hæc est finalis concordia*. A fine was also one of the methods of barring an Entail (q.v.), till the Fines and Recoveries Act of 1833 substituted a disentailing deed. Fine is also a name for a money payment imposed for an offence by a judicial authority. In some offences imprisonment may be imposed, in minor cases with, in more serious cases without, option of paying a corresponding fine.

Fingal's Cave. See STAFFA.—For Fingal himself, see FENIANS, OSSIAN.

Finger-and-toe. See ANBURY.

Finger-prints taken on paper by means of printing-ink or other medium show in every individual peculiar markings, which remain unchanged through life. Such finger-prints have been used as a means of signing or certifying documents in China and Japan from a remote antiquity. The use of finger-prints for criminal identification was first officially sanctioned in England in 1901, following work by Sir F. Galton, Sir W. J. Heischel, and Sir E. R. Henry. By means of radiography extraordinarily accurate representations may now be obtained. See Galton, *Finger-Prints* (1892).

Fingers. See HAND.

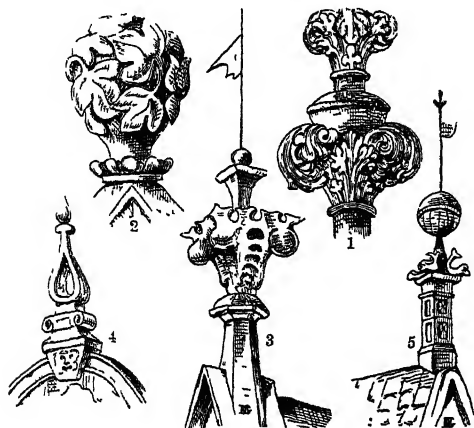

Fingos, or AMAFINGU, a Bantu people in the south-east of the Cape Province. See KAFFIRS.

Finial, an ornament, generally carved to resemble foliage, which forms the termination of pinnacles, gables, spires, and other portions of Gothic architecture. There are traces of foliated terminations, both in stone and metal, on the pediments of classic buildings (see ACROTERION), but it was not till the 12th century that the finial proper was introduced. During the latter part of that century and the whole of the 13th century, finials of the most perfect form and of infinite variety were used as the crowning ornaments of every salient point in the buildings of the period (see fig. 1). The architects of the 14th century in finials, as in other ornaments, imitated more closely the forms of natural foliage; but their finials had neither the variety of design nor the vigour of outline of those of the preceding century (see fig. 2).

In the 15th and 16th centuries the finials became more and more meagre in form, and are frequently only four crockets set upon a bare pyramidal terminal. Some variety of effect is often obtained during this period by surmounting the finial with a gilded vane. This is common in Tudor and in continental domestic architecture (fig. 3). Finials

were carved both in stone and wood, and in the latter material with great delicacy and minuteness. In connection with metal-work finials of metal were used, and, whatever the material adopted, its natural capabilities were made a source of special beauty.

The finial is one of the most effective ornaments of Gothic architecture, and when that style was succeeded by the Renaissance, in the reign of Queen Elizabeth, our forefathers could not persuade themselves to part with the finials to their buildings.

Finials:

1, from Bishop Bridport's Monument, Salisbury Cathedral; 2, York Minster; 3, Maulbronn, Germany; 4, Crew Hall, Cheshire; 5, Augsburg.

We thus find in Elizabethan architecture a great variety of finials; they are, however, almost entirely of a geometric form, and without foliage (fig. 4), and are frequently, especially when terminating wooden gables, combinations of finial and vane, partly wood and partly iron (fig. 5). In the stricter classic style which succeeded the Elizabethan, some traces of the favourite finial still remain in the balls, obelisks, &c. used as terminations, and also in the shields and supporters (themselves a remnant of feudal times) which form the crowning ornament of gate-piers, pedestals, &c.

Fining, the process of clearing turbid liquors, such as beer and wine. See CLARIFICATION, BEER, WINE, SUGAR, FILTER, &c.

Finistère (Lat. *finis terre*, 'land's end'), a département at the western extremity of France, comprehending a part of the former duchy of Bretagne, and washed on three sides by the English Channel and the ocean. Area, 2585 sq. m. Pop. (1872) 642,963; (1921) 762,514. It is traversed from east to west by two low but picturesque chains of hills, clad with fir-trees and heath, and forming fruitful valleys of meadow-land between. Its coast is very rugged and broken, its shores bristling with dangerous granite rocks, and fringed with many islands. The most dreaded headland is the Pointe de Raz, rising over 260 feet above the sea, near which, in the 16th century, were still visible the ruins of Is, the ancient capital of Cornouaille (q.v.). The temperature in general is low, the climate very humid: rain and mist are of almost daily occurrence. There are a number of coast streams, including the Odet, the Elorn, and the Anne, which forms part of the great line of communication between Brest and Nantes. The département raises more grain than even its dense population can consume, and vegetables, flax, and cider also are exported; it is noted for its small, hardy horses;

and cattle, swine, and bees are largely reared. Its argentiferous lead-mines are no longer worked, and its manufactures, which include rope-spinning, weaving, and some shipbuilding, are of little importance; its sardine-fisheries, however, are extensive. The département is divided into five *arrondissements*—Brest, Châteaulin, Morlaix, Quimper, and Quimperlé—with Quimper as chief town. See BRITANNY.

Finisterre, CAPE, a promontory at the north-western extremity of Spain, off which Anson (q.v.) defeated Jonquière, and Sir Robert Calder cut off two vessels of the Franco-Spanish fleet in 1805.

Finland (Finnish *Suomi* or *Suomenmaa*, 'the land of fens and lakes'), a republic of northern Europe lying between 60° and 70° N. lat., and 20° and 33° E. long., and bounded on the N. by Norway, on the E. by Russia, on the W. by Sweden and the Gulf of Bothnia, on the S. by the Gulf of Finland. Its greatest length is 717 miles, its average breadth about 185 miles. Its total area is about 144,000 sq. m. (or rather larger than Great Britain and Ireland). The surface consists of hard crystalline rocks, granite, gneiss, and schist, covered in most parts with a thin layer of infertile sands and clays. The drainage is bad, and the soil is soaked with water during most of the year.

The coast of Finland is extremely indented, and studded with thousands of small islands, forming a perfect archipelago (Swedish *skargård*), whilst the interior of the country, apart from the low coastal plains, and more especially in the southern as distinct from the northern or Lapland plateau, is covered with countless lakes. Some 12 per cent. of the total area is held to be so covered, while about 30 per cent. is occupied by marsh and bog, the quantity of which latter is, however, gradually being diminished by the united efforts of nature and man. The largest of the lakes—besides Lake Ladoga, of which part belongs to Russia—are Lakes Saima, Enare, Kemi, Oulujärvi, and Pajanne. The Saima consists of 120 large lakes and several thousand smaller ones, all connected, and having a natural outlet into Lake Ladoga, over the famous Imatra Falls—more correctly rapids—the finest in Europe from the point of view of scenery and the greatest in volume of water.

The interior of Finland forms a tableland of from 300 to 400 feet above the level of the sea, and there are no mountains worthy of the name, the highest being Haldefjall, in Lapland (Lapp *Haldischok*), 4126 feet high, near the frontier of Norway. The highest hill in the south is Turismaa, and this does not exceed 754 feet above sea-level. The principal rivers of Finland are the Kemi and Uleå in the north, and the Kymmene, the Kumo (Kokemäki), and the Vuoksen in the south. Owing to rocks and rapids they are usually navigable only for a part of their length, but they are well suited for floating logs from the forests of the interior to the coasts, and are also rich in fish; more important, they provide, as at the Inatrat (Vuoksen) and Anjala (Kymmene) Falls, a valuable source of water-power, a power, however, which is often severely curtailed by frost in winter and by drought in summer.

Relatively Finland is the most wooded country of Europe, more than half her land surface being under forest; even as regards absolute extent of forest area only Russia and Sweden exceed her. About two-fifths of Finland's woods are owned by the state, the remainder by private enterprise. The management of state forests is carefully regulated, and by a law of 1917 the reckless felling of timber by private individuals was prohibited. The Scots pine (*Pinus sylvestris*) and Norway spruce (*Abies* or *Picea excelsa*) are the most widespread and

most profitable; then come the birch, alder, ash, oak, &c., of which the three first mentioned alone grow far north, the others being found only in the centre and south of Finland. Among the fruit-trees which have been successfully acclimatised in Finland are the apple, pear, cherry, &c., but they produce no fruit in the north of the country beyond lat. 63°; currants, raspberries, strawberries, &c., thrive almost everywhere. The potato flourishes as far north even as lat. 69°, and of cereals, oats, rye, barley, and wheat are grown. The fauna of Finland is very rich. Among wild animals are the bear, wolf, fox, lynx, ermine, otter, elk, and hare; but the wild reindeer and beaver, formerly abundant, are now extinct. Seals are plentiful along the coast, as also in the Saima and Ladoga lakes. All domestic animals, replaced by reindeer in the far north, thrive in most parts of Finland. Of birds there are over 200 species—not counting the domestic sorts—including ptarmigan, blackcock, moorcock, swans, geese, ducks, many varieties of birds of prey, and most of the smaller birds common in Great Britain. There are some 70 species of fish in the rivers, lakes, and seas of Finland. Of these, a kind of herring (Swedish *stromming*) is very abundant on the south and south-west coasts. Salmon, trout, perch, pike, gwyniad, &c., abound in most of the rivers. Fish forms an important element in the food of all classes, large quantities, both smoked and salted, being stored for winter use.

Climate.—The climate of Finland is very rigorous in winter, even on the south coast, where 20° and 25° below zero (Fahrenheit) are often registered; but it is generally healthy, and, owing to the proximity of the sea, it is far milder than North Russia or any other region in the same latitude except Sweden and Norway. The summer, though short, is occasionally very hot in June and July. The ground is generally covered with snow from the middle of November till April; then follows a brief spring, accompanied by a rapid growth of vegetation. Autumn is likewise short, September being often very fine and October wet. The long summer days, when the sun only goes below the horizon for an hour or two, have a peculiar charm. At Helsingfors the mean temperature of the year is 39° (Fahrenheit), varying from an average of 17° in February to 62° in July. In the north and north-east of Finland, of course, the winters are longer and more severe, the mercury frequently freezing in the thermometer. The annual rainfall at Helsingfors is 20 inches, the prevailing winds being south and south-east. The country formerly suffered severely from occasional famines—the last was in 1868—owing to short or wet summers; but these disasters have now been obviated by means of railways, canals, and improved agriculture.

Industry.—Finland, though no more than a tenth of its area is under cultivation, is essentially an agricultural country. Thus about 65 per cent. of the inhabitants are engaged in agriculture, being for the most part peasant-proprietors with holdings of from 10 to 30 acres. The cultivated grounds lie for the most part along the coasts. Of cereals, oats is the most grown, then rye, barley, and a little wheat. Hay is an important crop, and the potato forms, after rye, the staple food of the inhabitants. Cattle and dairy farming are, however, the principal branches of Finnish agriculture. In addition to cattle—sheep, goats, and pigs are reared, while Finnish horses have long been remarkable for their speed, hardihood, and docility. Round the coasts fishing is an extensive industry, while river-fishing in the interior is also important. Apart from agriculture, lumbering and the production of wood-pulp and paper are the leading industries. Textile, leather, iron, and engineering works are also of considerable value. Industrial development gener-

ally, however, is greatly hampered through lack of minerals. Copper, tin, and gold exist, but iron is scarce, and there is no coal.

Commerce.—From the close of the 19th century the commerce of Finland as a Russian grand-duchy showed continuous and rapid expansion; and so also in the first years of the republic, exports in its fourth year, for the first time in the history of the country, definitely exceeding imports. Prior to this expansion the exports of Finland flowed eastwards by land to Russia, but their direction since has been increasingly westwards by sea to Europe (United Kingdom, Sweden, Denmark) and the New World (United States). Of exports, timber, pulp, and paper, and agricultural products (cattle, butter, cheese, hides, &c.) are the chief, while grains, colonial products (tea, coffee, sugar), metals, machinery, textile materials, and oils and fats are the principal imports.

Communications.—The harbours of Finland, peculiarly important in view of the increasingly westward character of her commerce, are many, but for the most part poor, both in themselves and in their equipment, while all, for some portion of the year at least, are icebound, with the exception of Pechenga, a port situated on a bay in the Arctic Ocean. In internal communications, however, Finland is probably better supplied than any other country in the world, her countless lakes being almost all connected with each other and with the Gulf of Finland either by nature or by canal. The Saima canal (36 miles), built in 1845–56, and linking the Saima lake basin with the Gulf of Finland, is reckoned a triumph of Finnish engineering. Railway building in Finland began about 1860, and some 2700 miles have been constructed, all, with the exception of one short line, belonging to the state. The telegraph, and especially the telephone, system is well developed, the first state owned, the second partly so.

Population.—The population of Finland, which was less than 1,000,000 in 1809, rose to 1,634,915 in 1850 and to 3,364,807 in 1920; it is densest on the coastal plains, especially of the south and south-west, the interior being but sparsely inhabited. In Helsingfors (Helsinki), the capital, there are 197,848 inhabitants, while in Åbo (Turku) there are 58,367; in Tammerfors (Tampere), 47,830; in Viborg (Viipuri), 30,071; in Vasa (Vaasa), 23,957; in Uleåborg (Oulu), 21,332. Of the population of Finland about 88 per cent. are of the native Finnish race, 11 per cent. Scandinavians (Swedes dwelling mostly along the southern and western coasts), the rest being Russians, Lapps, and Jews. Between Finns and Swedes racial feeling continues strong. The Finns are a Finno-Ugric people belonging to the great Ural-Altaic family. Physically they are a strong, hardy, athletic race, with round faces, square shoulders, fair hair, and blue eyes, though intermarriage with Scandinavians and Russians has in many cases caused variations. They are of a somewhat phlegmatic temperament, but are honest, hospitable, clean, and strictly moral. They were once distinguished by a love of strong drink, but since 1920 total prohibition has been in force. They possess many of the characteristics of the Mongolian races, to which they are ethnically related, and have a keen sense of independence and personal freedom, serfdom never having existed in the country except in the county of Viborg when it was in Russian hands.

Religion.—The Finns have long been famed as a religious people, and have been likened in this respect to the Scots. Of church members almost all belong to the national (Evangelic-Lutheran) church, though in the eastern parts of the country there are some 60,000 Greek-Catholics. Baptist, Methodist, Episcopal, and Roman Catholic churches

have quite insignificant followings. By law of 1922 religious toleration is complete.

Education.—The educational standard of Finland has always been very high, and to-day the percentage of illiteracy is almost negligible. As early as the end of the 17th century ability to read was made obligatory on all members of the church, and since 1866 a popular system of education has been in force. Instruction is given both in Finnish and Swedish. There are three universities, one at Helsingfors (Finnish-Swedish) and two at Åbo, one Finnish, one Swedish, while the technical (Finnish-Swedish) and commercial (2 Finnish) high schools at Helsingfors are all three of university standard. Secondary education is given in lyceums, high and middle schools, while in this category are also various institutions for the training of elementary and infant school teachers. Since 1920 elementary education has been compulsory, and here, apart from primary schools of the ordinary kind, there are also numerous navigation, commercial, trade, technical, arts and crafts, agricultural, dairy, cattle management, horticultural, and forestry schools.

History.—About the end of the 7th century or the commencement of the 8th the Finns, driven as is supposed by the Bulgarians from their settlements on the Volga, took possession of the country they now occupy; but they found inhabitants there already, whose memory popular tradition has handed down under the names of Hiidet, Jattilaset, Jatulit, and Jotunit. Probably the modern Lapps are the descendants of those primitive inhabitants. In the 12th century the Swedes turned their attention to Finland, seeking especially to introduce Christianity; but the struggle with paganism was long and obstinate, and lasted for nearly 200 years. Three separate crusades (1157, 1249, 1293), however, finally gave victory to Sweden and to the Christian religion. The first of these crusades was led by King Erik the Holy, accompanied by Henrik, Bishop of Uppsala, an Englishman by birth, who later, as Henrik the Martyr, became the patron saint of Finland. For over 600 years Finland was united with Sweden, and thus received the incalculable advantages of Christianity, civilisation, a constitution, and liberal laws. The Reformed religion was introduced into Finland by Gustavus Vasa in 1528, and King John III. raised the country to the dignity of a grand-duchy. The theatre of frequent bloody struggles between Russia and Sweden from the middle ages onwards, Finland was ultimately ceded to Russia in 1809, and became an autonomous grand-duchy with the emperor of Russia as grand-duke. Alexander I. promised the Finns that their constitution, religion, and laws should be faithfully preserved, and though the parliament or diet of nobles, clergy, burghers, and peasants, which the Finns had enjoyed from the days of Swedish rule, did not after 1809 reassemble till 1863, the promise was virtually kept till near the end of the century, autonomy being all but complete except in foreign affairs. But in 1898 imperial decrees altering the military system, and invading the privileges of the parliament, caused bitter discontent, the more so as throughout the century the tide of national and democratic feeling had been steadily rising. In 1899 the Finnish constitution was suspended, and under General Bobrikoff a military dictatorship established. In 1901-3 various ordinances further destroyed the autonomy of Finland, and reduced it to the condition of a province. The assassination of Bobrikoff in 1904 brought certain concessions and the restoration of some old privileges, but in 1909 a Russifying policy was resumed, and more markedly, if anything, after the commencement of the Great War in 1914. On the first outbreak, in

1917, of revolution in Russia, Finland recovered all her former rights, but complications ensued with the advent and triumph of bolshevism. Divided against herself as to the acceptance of soviet doctrine, and seeking escape from entanglement in Russian affairs, independence was proclaimed in December 1917. But civil war ensued, in which the revolutionary Red Guards, supported by men and materials from Russia, were eventually defeated in May 1918 by the constitutional White Guards, supported by men and materials from Germany. P. E. Svinhufvud became for the time being regent, and a monarchical form of government being subsequently definitely determined on, the crown was offered to Prince Frederick Charles of Hesse. On his refusal, however, General C. G. Mannerheim, who had led the White Guards to victory, became regent, and continued so till, following elections in 1919, a republic was proclaimed with Professor K. J. Ståhlberg as first president. In 1920, by the treaty of Dorpat, Finland established peace with Russia, and also secured the territory of Pechenga, so extending her boundaries to the Arctic Ocean. In the same year she was admitted to the League of Nations, and in 1921 was confirmed by the League in her retention of the Åland Islands, which, on the plea of self-determination, had demanded annexation to Sweden.

Constitution.—Finland is a sovereign republic. Ultimate power resides in the people as represented in a House of Representatives or Diet, a single chamber assembly of 200 representatives chosen directly by universal (male and female) suffrage on a system of proportional representation. A president elected for six years by vote of the citizens is head of the state. He possesses the highest executive power, and along with the Diet the right of initiative.

Language and Literature.—Swedish was formerly the official language of Finland, but since 1883 Finnish and Swedish have been placed on a footing of equality, and now the importance of Swedish is steadily decreasing. Finnish, held by some to be one of the most sonorous and harmonious of tongues, is of the Ugro-Finnic branch of the Ural-Altaic family, which comprises Ugro-Finnic, Manchu, Mongol, Turkish, and Samoyede (see ASIA). The group includes (1) Finn and Estonian (q.v.), (2) the tongue of the Lapps, (3) of the Finns of Perm, (4) of the Finns of Vologda, and finally (5) that of the Ugrian Finns, to which last belong the Vogul and Ostiak dialects in Siberia, and the Magyar in Hungary (see HUNGARY). The most highly cultivated language of the group is that spoken by the Finns proper, the Suomi of Finland. The Finnish dialects are all agglutinative forms of speech, with tendencies towards true inflection, so that occasionally the difference between agglutination and inflection is somewhat obscure. The nouns are not inflected, an additional word being used to denote the variations of case, number, and sex, whilst the prepositions and pronouns are suffixed to the words they modify. The verbs have only a present and past tense, another word being required to indicate the future.

The founder of Finnish literature is the Bishop of Åbo, Michael Agricola (d. 1557), who, besides translating the New Testament (1548) and parts of the Old, wrote also a primer and a prayer-book. His followers were mostly men of the church, makers of manuals and books of devotion, and writers of spiritual verse. In the 16th and 17th centuries, however, the output of Finnish literature was small, Latin or Swedish being preferred as literary languages. But in the 18th century new tendencies came into being, and H. G. Porthan (1739-1804), by stimulating interest in history and popular poetry, prepared the way for great de-

velopments in the century following. In 1822 was published by Z. Topelius, whose son of the same name was later to become a distinguished author, a collection of scattered songs, while in 1831 an association for the promotion of Finnish literature was established. But the great event of the time was the appearance in 1835 (in greatly extended form in 1849) of the *Kalevala*, an epic poem formed by E. Lönnrot (1802-84) out of a collection of popular songs taken down from the lips of the peasantry as they from time immemorial had heard them from their *Runolainen* or singers. The poem, which is a singular monument of the earlier culture of the Finns and of the utmost value philologically, gave a new impetus to the study of Finnish in Finland, and became, along with the *Kanteletar* (1840), a collection, also by Lönnrot, of national lyrics, the source and inspiration of a rich and very remarkable literature. An idea of the form and metre of the poem may be obtained from Longfellow's *Hiawatha*, known to be in imitation of the epic. The work, which has been translated into many languages, has been favourably compared with the *Iliad*, and has been placed fifth among the national epics of the world. As writers of original Finnish poetry A. Oksanen (A. E. Ahlqvist, 1826-89) and Suonio (J. Krohn, 1835-88) must be considered the first representatives in modern times, but in the lyric and patriotic songs of J. H. Eikko (1849-1906) the work of both was surpassed. K. Kramsu (1855-95) is a melancholy tragic-lyrist singing of freedom and the rights of the oppressed, while P. Cajander (1846-1913), though also a prominent lyricist, is mainly distinguished by his translation into Finnish of all the dramas of Shakespeare. The first noted novelist and dramatist is A. Kivi (1834-72), whose novel *Seitsemän Veljestä* ('Seven Brothers') and comedy *Nummisuutarit* ('The Shoemakers from the Moor') are still without rivals in Finnish literature. About 1880, largely through the influence of modern Scandinavian writers, Ibsen and Björnson in especial, a powerful realistic tendency appeared, and revealed itself in the novels of M. Canth (1844-97), the first noted woman writer of Finland, of J. Aho (1861-1921), of A. Järnefelt (b. 1861), of T. Pakkala (b. 1862), and of others. From time to time self-taught men from the peasantry of Finland have devoted themselves with success to letters. In his verse J. Linnan-koski (1869-1913) reflects the influence of Byron, while in his prose he is unsurpassed in Finnish literature. Amongst prominent novelists of to-day are S. Ivalo (b. 1866), J. Lentonen (b. 1882), F. E. Sillanpää (b. 1881), M. Tolvio (b. 1871), M. Jotuni (b. 1880), and A. Kallas (b. 1878), the last three women; while foremost amongst poets are V. A. Koskenniemi (b. 1885), L. Kyösti (b. 1873), and O. Manninen (b. 1872), who has also translated the *Iliad*. Apart from H. G. Porthan, already mentioned, Y. Koskinen (born G. Z. Forsman, 1830-1903) is the greatest name in Finnish historical research, while, as a sociologist, E. A. Westermarck (b. 1862) enjoys a European reputation.

From the days of Swedish dominion much of the greatest literature of Finland has always been written in Swedish. J. Frese (c. 1690-1729) was a prominent lyricist, and G. F. Creutz (1731-85), in his *Atis och Camilla*, a pastoral idyll in the rococo style, produced one of the most exquisite creations in Swedish verse, but greater than both was the poet F. M. Franzén (1772-1842). J. L. Runeberg (1804-77) is, however, the most brilliant name by far in the Swedish literature of Finland; his greatest achievements are in the epic form, and his *Elgskytarna* ('The Elk Hunters') left deep traces on the literature of both Finland and Sweden, while his *Fänrik Ståls Sägner* ('The

Tales of Ensign Stål') earned for him the title of 'Finland's national poet.' The journalist J. W. Snellman (1806-81), the poet F. Cygneus (1807-81), and the poet and prose-writer Z. Topelius (1818-98), whose *Faltskarens berättelser* ('The Tales of the Surgeon') has achieved a classic value, were all contemporaries of Runeberg, and all with him leading inspirers of Finnish national sentiment. Of representatives of modern realism K. A. Tavaststjerna (1860-98), lyric poet, and writer of drama and romance, is the chief, while of living Swedish authors of note in Finland are the poet and prose-writer M. Lybeck (b. 1864) and the lyricists H. Procopé (b. 1868), B. Gripenberg (b. 1878), A. Mörne (b. 1876), J. Tegengren (b. 1875), and J. Hemmer (b. 1893).

Fine Arts.—The engraver and miniature painter E. Brenner (1647-1717), the religious painter M. Toppelius (1734-1821), and the portrait painter, N. Schillmarck (d. 1804) are among the first of Finland's artists; but it is not till after the founding, in 1846, of the Finnish Association of Art that a specific Finnish art may really be said to exist. R. W. Ekman (1808-73) was the pioneer, but the landscape painter W. Holmberg (1830-60) was the first Finnish artist who could be judged according to European standards. A product of the school of Düsseldorf, he was followed by many in like style, most noticeably H. Munsteihjelm (1840-1905) and B. Lindholm (1841-1914). A. Edelfelt (1854-1905), illustrator, portraitist, and genre painter, was the first Finnish artist to come altogether under the influence of France, and later, through the power of his work, he completely established the French conception of art in Finland. A. Gallen-Kallela (b. 1865), figure and landscape painter, is to-day the most powerful artistic personality of Finland, while among his distinguished contemporaries are E. Järnefelt (b. 1863) and P. Halonen (b. 1865). Among the younger generation of Finnish painters, impressionist and neo-impressionist schools are fully represented. In M. Wiik (b. 1853), E. Danielson-Gambogi (1861-1920), and H. Schjerfbeck (b. 1862), Finland has produced three prominent woman-painters.

Finland's first sculptor was E. Cainberg (1771-1816), but C. E. Sjöstrand (1828-1906), a Swede, was the real pioneer. Among his disciples of note, W. Runeberg (1838-1920), son of the poet, and J. Takanen (1849-85) are to be numbered. Since 1870 the influence of France has been supreme, as is clearly to be seen in the work of V. Vallgren (b. 1855) and E. Wikström (b. 1864), and in the sculpture of the younger school, which has turned in especial to Rodin. The architecture of Finland is really a product of the 19th century, and, in so far as it is represented in Helsingfors, is mostly neo-classical and new-renaissance in style.

The Finns are a musical people, and earlier than any of the other arts music was purposely pursued amongst them, a musical society having existed at Åbo as early as 1790. In B. Crusell (1775-1838) Finland found her first composer, but the German, F. Pacius (1809-91) and his successor R. Faltin (1835-1918) were the real initiators of the musical life of the country. Among earlier composers, K. Collan (1828-71), F. von Schantz (1835-65), K. Moring (1832-68), and G. Linsén (1838-1914) are the chief. After 1880 the activity of M. Wegelius (1846-1906) and R. Kajanus (b. 1856), both as composers and as conductors, produced epoch-making effects on Finnish musical life, and later, amongst others, appeared J. Sibelius (b. 1856), a composer of genius and international fame, and a true interpreter of the real Finnish spirit in music. The drama and opera both flourish in Finland, and there is a national theatre at Helsingfors.

Finland, GULF OF, the eastern arm of the Baltic Sea, between 22° and 30° E. long., and between 59° and 61° N. lat. It receives the waters of the great lakes Onega and Ladoga. The water of the gulf is not deep, and only very slightly salt. The topography of the Gulf of Finland, which has been thoroughly elucidated by Struve, forms an interesting part of the great work of the Russian survey of the Baltic. The navigation on the northern or Finnish coast is very dangerous, on account of the numerous islands and shoals.

Finlay, GEORGE, the historian of Greece, was born of Scottish parents at Faversham, in Kent, where his father, Major John Finlay, was inspector of the government powder-mills, 21st December 1799. After his studies at Glasgow and Göttingen, Philhellenism carried him to Greece, where he met Lord Byron, and devoted himself with patient enthusiasm to the study of Greek history and antiquities. With the exception of a short period of residence in Rome, and of study at Edinburgh University, the whole of his life was spent in the land of his adoption, which he continued to love, spite of the unworthiness of its leaders and of the miserable failure of his own generous schemes for promoting agricultural progress. For relief he turned to the task of writing its history. 'Had the hopes with which I joined the cause of Greece in 1823 been fulfilled,' he wrote in 1853, 'it is not probable that I should have abandoned the active duties of life, and the noble task of labouring to improve the land, for the sterile task of recording its misfortunes.' The first portion of his great work, *Greece under the Romans*, appeared in 1844, and was followed by the following instalments: *The History of Greece from its Conquest by the Crusaders to its Conquest by the Turks, and of the Empire of Trebizond, 1204-1461* (1851); *History of the Byzantine and Greek Empires from 716-1453* (1854); *History of Greece under Ottoman and Venetian Domination* (1856); and *History of the Greek Revolution* (1861). Finlay devoted the remaining years of his laborious life to revising and partly rewriting his history, but his death at Athens, 26th January 1875, prevented his completing the work, which was issued by the Clarendon Press, under the care of the Rev. H. F. Tozer, with the title, *History of Greece from B.C. 146 to A.D. 1864* (7 vols. 1877; vol. i. contains an autobiography). Freeman declares his history the greatest English historical work since Gibbon's *Decline and Fall*.

Finnmark, the most northern province of Norway, consists of a narrow strip of rocky coast-land, cleft by numerous bays and fjords. The area is 18,295 sq. m., of which three-fourths belong to the continent, the rest to the numerous islands which skirt its shores. The chief sources of wealth are fishing and reindeer breeding. Only very scanty crops of barley, potatoes, and a few other vegetables are raised. Population 44,000, principally Lapps. Hammerfest, the capital (70° 40' N. lat.), with near 3500 inhabitants, is the most northern town of Europe. See Du Chaillu's *Land of the Midnight Sun* (1881).

Fins, a term vaguely applied to outgrowths and limbs in aquatic animals; the paired fins of fishes being true limbs. See FISHES.

Finsbury, a parliamentary borough of London, consisting in 1885-1918 of three one-member divisions, Holborn, Central, and East. In 1899 the two latter were formed into the metropolitan borough of Finsbury, which in 1918 became a one-member parliamentary borough; pop. 76,000.

Finsen, NIELS R. (1861-1904), discoverer of the curative power of the chemical rays of light (sunlight, electric light, Röntgen rays, &c.) and founder of phototherapy, was born in the Faeroe Isles, and taught anatomy at the university of Copenhagen, where he had studied.

Finsteraarhorn, the highest peak (14,026 feet) of the Bernese Alps. See ALPS.

Finsterwalde, an old town of Prussia, 71 miles by rail S. by E. of Berlin, with manufactures and coal-mines; pop. 14,000.

Fiord. See FIRTH, NORWAY.

Fir, a name applied in a comprehensive sense to the true Pines, the Larch, and certain other conifers, but more properly used to denominate the Norway Spruce, the Silver Fir, and their congeners. These two species—now the types respectively of the genera *Picea* and *Abies*—were included in the Linnæan genus *Pinus*; thus, the Norway Spruce was *P. Abies*, and the Silver Fir was *P. Picea*. By these specific names the trees were known to Pliny and other ancient writers, but by inadvertence on the part of Linnæus they were misapplied so that each bore the other's name. This confusion was perpetuated when the species were removed from the genus *Pinus*, and set up as representatives of distinct genera. As kindred species were discovered and introduced, nomenclature became more confounded. Continental botanists endeavoured for long with only partial success to restore the names *Picea* and *Abies* to their ancient use. The point, however, was at length conceded in the *Genera Plantarum* (1862-76) by Bentham and Hooker; but amateurs and students of coniferæ will still be confronted with the confused nomenclature of the species in works on the subject published prior to the adoption of this change of the generic names. Their difficulty will, however, be lessened by their bearing in mind that species ranged in old books under *Abies* must now be named *Picea*; thus, for instance, the Norway Spruce is no longer *Abies* but *Picea excelsa*, and the Silver Fir is *Abies pectinata*, not *Picea* of that designation.—It should also be noted that some trees commonly called fir are really pines; thus, the so-called Scotch Fir (*Pinus sylvestris*) is a pine. See PINE.

The genus *Abies* comprises somewhere about twenty species, which are easily distinguished from the Spruce Firs by their erect, cylindrical or but slightly tapering cones, the scales of which are deciduous and fall away in maturity from the axis, which adheres to the branch; and by their flattened leaves being always more or less distinctly arranged in two ranks on each side of the branches, and generally in a horizontal direction. The genus *Picea* consists of about twelve species, the cones of which are pendulous, and the scales persistent, opening only when mature to shed the seeds. The leaves are arranged spirally, scattered around the branches, needle-like and quadrigonal or almost round. These are the broad essential distinctions of these two genera of firs, but they have some features in common. They are all evergreen-trees, mostly of spiral or pyramidal habit, their branches spring from the stem in whorls—a characteristic of certain other conifers—and the scales of the cones are thin or almost scarious at the apex, a point

which distinguishes them from the true pines. The species of both are widely distributed over the extra-tropical regions of the northern hemisphere, and the Norway Spruce even penetrates within the Arctic circle.

The last-named species, *Picea excelsa*, is one of the noblest and most useful of European firs, attaining the height of from 80 to 150 feet, but with no proportionate diameter of trunk, which is usually rather slender compared with its height. It is a native of the north of Germany, Russia, and Norway, where it forms immense tracts of natural forest. Since its introduction into Britain about 1540, it has been extensively planted, chiefly as a nurse for more tender and slower-growing trees, for which purpose its evergreen character and hardy constitution adapt it well. It does not succeed in windy, exposed situations, nor in thin, dry soil, but in moist, alluvial soil it attains its highest development. It is the *Fichte* of the Germans, called also *Rottanne* or *Schwarzanne*.

It yields the same products as the Scots Pine—resin, turpentine, tar, and lamp-black (see these heads); but more resin than turpentine. The true Spruce Resin flows spontaneously from the bark. The purest pieces are whitish or pale yellow, are sold under the name of Common Frankincense, and used for ointments and plasters, and when melted yield

the common Burgundy Pitch (q.v.). The bark of the spruce is a good and cheap non-conductor of heat; the cones are an excellent substitute for tanners' bark. In Sweden and Norway the inner bark is made into baskets; and the long and slender roots, split and boiled with alkali and sea-salt, are dried, and twisted into cordage, which is used both for shipping and by farmers. The wood is used for fuel and for house-building; it also supplies masts and spars for ships. It is the White Christiania deal and Danzig deal of the market, and is very largely imported into Britain from Norway and the Baltic. It is whiter, lighter, less resinous, and more elastic than the timber of Scots Pine. The sapwood, whilst still in a gelatinous state, is sweet, and is eaten fresh in Sweden and Lapland; and the inner bark, in times of scarcity, is mixed with a little flour or meal of some kind and baked into bread. The young shoots, still covered with their bud-scales, are in many parts of Europe used for fumigation. The leaf-buds are also employed medicinally in cases of scurvy, rheumatism, and gout. The pollen is often sold by apothecaries instead of the dust of the Clubmoss or Lycopodium.

A very superior variety of this fir is known as the Red Norway Spruce. Dwarf varieties are cultivated amongst ornamental shrubs. The Black Spruce (*Picea nigra*), of which the Red Spruce (sometimes called *P. rubra*) is regarded as a mere variety caused by difference of soil, and the White Spruce (*P. alba*) form great woods in North America. The Black Spruce is found as far north as 65° lat. Both these species are now common in plantations in Britain. Both have quadrangular leaves; those of the Black Spruce are of a dark glaucous green, those of the White Spruce are of a lighter colour. The cones of the Black Spruce are short, ovate-oblong, obtuse, and pendulous, with rounded scales ragged at the edge; those of the White Spruce are oval, and tapering to a point, with entire scales. The Black Spruce is a valuable timber-tree, supplying yards of ships, &c.; but its planks are apt to split. The White Spruce is smaller, and the timber inferior. From the Black Spruce the *Essence of Spruce* is obtained, which is held in estimation as an antiscorbutic, and is used for making spruce-beer. Spruce beer is also made by adding molasses or maple-sugar to a decoction of the young branchlets, and allowing the whole to ferment. From the fibres of the root of the White Spruce, macerated in water, the Canadian Indians prepare the thread with which they sew their birch-bark canoes; and the seams are made watertight with its resin. From the twigs of the Oriental Fir (*P. Orientalis*), a native of the Levant, a very fine clear resin exudes, which is known by the name of Sapidus' Tears. This fir has very short quadrangular leaves, densely crowded and uniformly imbricated. The Sitka Spruce (*P. Sitchensis*) and Patton's Spruce (*Tsuga Pattoniana*) are now prized as ornamental trees in pleasure-grounds in Britain: both are natives of Western America, the former covering wide areas at from 7000 to 9000 feet elevation. It makes rapid growth in Britain, and apart from its ornamental value it has been suggested that it should be planted more extensively for its timber, which is described as very durable, though rather coarse grained. In southern California Patton's Spruce attains the height of from 200 to 300 feet, with a circumference of trunk of from 12 to 14 feet; but in northern California, where it is also found in great abundance at elevations of from 4000 to 6000 feet, it reaches the height of 150 feet as its maximum dimensions, towering above the rest of the forest at the lower levels, but dwindling as it ascends the mountains to the proportions of a shrub a few feet high. It is a slow-growing, but very handsome tree in Britain, with light-green, rigid, thickly set leaves having a glaucous tint below, which enhances its beauty. The Himalayan Spruce (*P. Morinda*) is a remarkably graceful tree found at elevations of from 6000 to 12,000 feet on the Himalayas. Where it succeeds well in Britain, it is one of the most beautiful of pleasure-ground trees, but should not be planted in cold districts. The leaves are longer than those of most other Spruce Firs, and densely clothe the branches, which assume a graceful pendulous outline. The Korean Spruce (*P. polita*) is a comparatively recent introduction to Britain. It forms vast forests on the mountains of Korea, and is indigenous also to Japan. In England it is a slow-growing tree, and should be planted only in sheltered situations.

The Hemlock Spruce of North America (*Tsuga canadensis*) forms great part of the forests of Canada, and of the northern states, extending northwards as far as Hudson's Bay. Its timber is not much esteemed, as it splits very obliquely, and decays rapidly in the atmosphere; but the bark is valued for tanning. The leaves are two-rowed, flat, and obtuse. The cones are scarcely

longer than the leaves. The young trees are very graceful, but the older ones are generally much disfigured by remaining stumps of their lower branches.—The Douglas Fir (*T.* or *Pseudotsuga Douglasii*) is a noble tree

Fig. 2.—Cone of Douglas Fir (*Pseudotsuga Douglasii*).

attaining a height of 250 feet, which forms immense forests in the north-west of America, from 43° lat. to 52° lat. The bark, when the tree is old, is rugged, and 6-9 inches thick. It abounds in a clear, yellow resin. The timber is heavy, firm, and valuable, the growth very rapid. Experimental plantations of this extremely rapid-growing tree laid down in 1860 by the Earl of Mansfield on his Scone estates, Perthshire, encourage the expectation that it will rival and perhaps

surpass the larch in value as a timber tree.

The Mount Enos Fir (*A. cephalonica*), a native of Cephalonia, attaining a height of 60 feet and a diameter of 3 feet, yields durable and very valuable timber.—All these species have been introduced into Britain, and many of them are now common in our plantations, as well as others from the north-west of America and from the mountains of Asia, and are apparently quite suitable to the climate. The Common Silver Fir (*Abies pectinata*) has erect cylindrical cones, 5-6 inches long, and two-rowed leaves, with two white

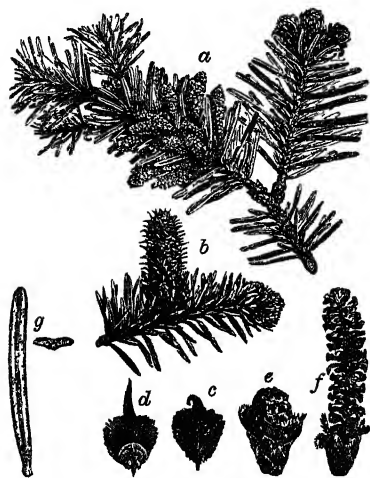

Fig. 3.

Common Silver Fir (*Abies pectinata*):

lines upon the under side. It forms considerable woods upon the mountains of Central Europe and of the north of Asia, and attains a height of 150-180 feet and an age of 300 years. It is not a native of Britain, but large trees are now to be seen in very many places. The wood is white, contains little resin, is very soft and light, and is employed for the ordinary purposes of coopers, turners, and joiners, and in ship and house carpentry, also for making boxes and for many fine purposes, especially for the sounding-boards of musical instruments. The same resinous and oily products are obtained from the Silver Fir as from the Spruce and Scots Pine, but of superior quality. It yields the beautiful clear turpentine known as Strasburg Turpentine. Very similar to the Silver Fir, but generally of much smaller size, and indeed seldom much above 30 feet in height, is the Balm of Gilead Fir (*Abies balsamea*), a native of North

America from Virginia to Canada. The wood is of little value, but the tree yields Canada Balsam (q.v.).

Besides these, a number of other species of *Abies* are found in the western parts of North America and in the Himalayas, some of which are trees of great magnitude, and yield excellent timber, as *A. grandis*, a Californian tree of 170-200 feet in height; *A. amabilis*, a species much resembling it; *A. nobilis*, a majestic tree, which forms vast forests on the mountains of northern California; *A. bracteata*, a Californian species remarkable for its slender stem, which rises to a height of 120 feet, and yet is only about 1 foot in diameter at the base, and likewise for the manner in which the middle lobe of each bract of its cones is produced so as to resemble a leaf; *A. Webbiana*, the Himalayan Silver Fir, which in its native regions fills the upper parts of mountain-valleys, and crowns summits and ridges at an elevation of upwards of 10,000 feet, a tree of great size, 35 feet in girth, and with a trunk rising 40 feet before it sends out a branch. Most of these have been introduced into Britain with good prospect of their succeeding well in our climate, and other species, as *A. Sibirica*, a native of the Altai Mountains, very nearly resembling the Silver Fir, *A. Nordmanniana*, *A. Fraserii*, &c. *P. religiosa* is a tall and elegant tree, a native of the mountains of Mexico, with slender branches, which are very much used by the Mexicans for adorning churches; and its cones are shorter than those of any other Silver Fir.

Firbolgs, the name given in the fabulous history of Ireland to one of the races who successfully invaded that country in what was probably the bronze age. The various tribes of the Firbolgs seem to have been Britons, and were said to have landed in Ireland under the command of five principal chiefs in three separate divisions, one in the river Slaney, the second in Mayo county, and the third in Ulster. Their chief stronghold, called Dind Rig, was near the Barrow, in Carlow. The Firbolgs were in their turn defeated and almost exterminated by a new race of invaders, the Tuatha Dé Danann, in a battle fought at Moytura, in Mayo. Nevertheless, the race did not wholly perish, for there long continued to be Firbolg kings of Connaught, and in the time of St Patrick it was in all probability the Firbolgs who constituted the bulk of the population of Ireland.

Firdausí, or **FIRDUSÍ**, the *takhallus* or *nom de guerre* (the term signifies both 'garden' and 'paradise') of Abú'l Kásim Mansúr, the greatest of Persian poets, was born about the year of the Flight 328 (939-940 A.D.), at Shadáb, a dependent township of Tús, in Khurásán, of a stock of *dihlans*, or petty landholders. He spent the greater part of his life on the paternal estate, wedded to his studies. From his grand epic, the *Shah Náma*, or Book of Kings, he has been styled by European *savants* 'the Homer of Persia.' Among the spoils gained by the Arabs at the downfall of ancient Iran was a complete history of Persia, compiled by order of Yazdajird, the last of the Sassanian dynasty, by the most learned historians, which was presented as a valuable gift to the Calif Omar—the reputed destroyer of the famous Alexandrian library. The calif caused this work to be rendered into Arabic, and luckily did not order its destruction, but left it to its chance among the general plunder, when it fell into the hands of a common soldier. The history of this Pahlavi work for some centuries is obscure, but at length it came into the possession of Mahmúd, sultan of Ghazni, whose court was crowded with the most eminent men of learning from all quarters. Mahmúd ordered Dakikí, the most illustrious poet at his court, to render the work into Persian verse, but he had not proceeded far with his task when he came to a tragic end. In his fifty-eighth year Firdausi resolved to visit the court of Mahmúd, but it was not easy to gain admission to the presence; yet, in spite of the resentment of the sultan's favourites at the intrusion of a stranger, he contrived, by means of a friend with whom he lodged, to convey to the sultan a specimen of his epic (he had been for years engaged upon the work which the death of Dakikí had left undone), and the result was an invitation to court. Mahmúd ordered his vazir to pay Firdausi a thousand gold dinars (about £500) for every thousand finished couplets; but the poet, having from early youth had the ambition to construct a canal-dam (*bund*) on his patrimonial estate for the benefit of his townsmen, preferred to receive the accumulated amount when he had completed his poem. The vazir of Mahmúd was secretly inimical to Firdausi, and accused him to the sultan of a decided leaning to the doctrines of Zoroaster; but his efforts as well as those of the other courtiers to undermine Mahmúd's confidence were of no avail, and Firdausi continued to enjoy the royal patronage.

Portions of the *Shah Náma* as they were written were often transcribed and circulated and admired far and wide. It is said that he was offered rich presents from the neighbouring princes, which he constantly declined. The later years of Firdausi's life in Ghazni—he seems to have dwelt some twelve years there altogether—were darkened by the death of his son in early manhood, whom he pathetically laments towards the end of his great epic.

At length, after thirty years' toil, the *Shah Náma* was finished in 398 A.H. (1008 A.D.), and the poet presented his monumental work to Sultan Mahmúd, who at once ordered his vazir to pay Firdausi 60,000 gold dinars—but no copy of the epic extant comprises more than 56,600 couplets, and some of these are evidently interpolations. The envious minister, however, despatched the same number of silver dirhams instead (the value of a dirham is about sixpence) in sealed bags. The poet was in the bath when the messenger arrived. 'On opening the bags, his lofty spirit felt all the indignity which he imagined the sultan intended to load him with. He immediately gave 20,000 to the keeper of the baths (*hammámí*), the same sum to the sherbet-seller, and the remainder to the slave who had brought the money.

"I wrote for fame," said he to the slave, "not for the attainment of riches." When the slave told the whole affair to Mahmúd, he was enraged at the insolence of his vazir, and said: 'This action will not only irritate the poet, but mankind will reprobate a sordid parsimony injurious to my fame. I ordered gold dinars to be sent, and you have substituted silver dirhams.' To this the wily vazir rejoined that whatever the sultan gives confers honour on the recipient, and it was insolent in Firdausi to treat any donation of his majesty with contempt. These and other insinuations ultimately aroused Mahmúd's indignation, and the poet, fearing the consequences, fled on foot from Ghazni, but not before he had composed and left behind him a most scathing satire on the sultan. Tidings of Firdausi's flight and the cause soon spread throughout Asia, and the sultan's conduct was severely condemned by the noble and the learned everywhere. For some time the poet was protected by the Nasir Al-Mutasim of Kohistán, but, he being a dependant of Mahmúd, Firdausi was again compelled to flee, first to Mazandarán and then to Baghdád. The sultan, however, hearing where the poet was residing, ordered him to be sent a prisoner to Ghazni; but the calif, unwilling to deliver Firdausi up to the tender mercies of Mahmúd, and being powerless to withstand the sultan, wrote to Mahmúd to the effect that Firdausi had been at his court and was now gone to El-Yaman; and it was with unspeakable grief that he saw the venerable poet once more become a fugitive. But instead of going to Arabia, Firdausi proceeded to Tús, his native place, where he hoped to pass the remaining years of his life in tranquillity.

The wrath of Mahmúd was at length softened into pity, and he ordered the 60,000 gold dinars to be carried to Firdausi at Tús. 'One day, while the poet was walking in the market-place, as a boy was reciting a verse from his satire on the sultan, he fainted, and was carried to his house, where he expired (411 A.H.: 1020 A.D.), without uttering a word. As his remains were being carried to the grave, the present from the sultan arrived at Tús. It was presented to the poet's daughter, who, contrary to the advice of her aunt, declined its acceptance, saying that, as her father did not receive the present in his lifetime, it would ill become her to accept what he declined.'

The *Shah Náma*, while probably based upon actual historical events, is for the most part composed of mythological and purely fanciful incidents, but these are adorned with all the glowing imagery of the Eastern imagination; while true descriptions of human nature and pathetic scenes are of frequent occurrence—such as, for instance, the fine episode of Rustam (the Hercules of Persia, and the chief hero of the epic) and Súhráb, which is unexcelled in its kind in the poetry of any country. We have an admirable example of fairy lore in Rustam's seven labours to slay the White Demon, in which the hero's horse Raksh ('lightning') plays no unimportant part. The following lines, which occur in the *Shah Náma*—

Choose knowledge,
If thou desirest a blessing from the universal Provider;
For the ignorant man cannot raise himself above the earth,
And it is by knowledge that thou must render thy soul praise-worthy—

find their very echo in Shakespeare's saying, that

Ignorance is the curse of God;
Knowledge, the wing wherewith we fly to heaven.

Besides his immortal epic Firdausi wrote a number of shorter pieces, *kasidas*, *ghazals*, &c., which are preserved in several Persian anthologies. He was the first, apparently, to compose a poem on the wife of Potiphar and Joseph, under the title

of *Yūsuf u Zūlaykhā*, a subject which has been a great favourite with many later poets, Turkish as well as Persian.

See Atkinson's epitome of the *Shah Nāma*, with numerous passages done into English verse; Sir Gore Ouseley's *Biographical Notices of Persian Poets*; Miss Zimmern's *Epic of Kings*; Browne's *Literary History of Persia* (1902-6); Robinson's *Persian Poetry for English Readers* (1883); the works of Von Hammer, Wahl, Gorres, and Ethé.—There are many beautifully illuminated manuscripts of the *Shah Nāma* preserved in the great European libraries, and the complete text was edited by Turner Macan (4 vols. Calcutta, 1829). In 1811 Lumsden, of Calcutta, had published a portion of the text. There is a complete French translation by Juhus Mohl, with the Persian text on the opposite page (7 vols. Paris, 1838-78). Another edition by Vullers was continued by Landauer (1877-84). There is an Italian translation by Pizzi (8 vols. 1886-88); Rückert's German translation (1890) is incomplete; a translation into English verse by A. G. and E. Warner was published in 1905 and following years.

Fire. Countless stories of fireless men have been retailed by credulous travellers, and there is hardly a primitive mythology which has not woven a web of fable round its origin; not seldom it is ascribed to a special theft from the gods by some greatly daring hero, like the Greek Prometheus or the New Zealand Maui. As far as actual knowledge goes we find that the possession of fire and the art of making it by one method or other have belonged to the vast majority of mankind as far back as we can trace. The original method of finding fire was undoubtedly by the simple friction of two pieces of wood, which was developed by progressive art into more complex and convenient methods. One of the simplest methods in use is what Sir E. Tylor terms the 'stick-and-groove,' in which a blunt-pointed stick is run along a groove of its own making in a piece of wood lying on the ground. By this means a Tahitian can produce fire in a few seconds. Somewhat similar is the Malay process of striking fire by rubbing together two pieces of split bamboo, which has been conveniently fitted by nature with a siliceous coating. Again, the most widespread method is that to which Tylor applies the term 'fire-drill'—a primitive kind of boring instrument, thus described by Captain Cook from his observations of the native Australians: 'They take two pieces of dry soft wood; one is a stick about eight or nine inches long, the other piece is flat: the stick they shape into an obtuse point at one end, and pressing it upon the other, turn it nimbly by holding it between both their hands, as we do a chocolate-mill, often shifting their hands up, and then moving them down upon it, to increase the pressure as much as possible.' Many improvements upon this simple method are found, as that on the principle of the carpenter's brace used by the Gauchos of the South American pampas; the Eskimo method of winding a cord round the drill, so as by pulling the two ends alternately to make it revolve very rapidly; the Sioux bow-drill, in which a bow with a loose cord is substituted for a simple cord; and the pump-drill, familiar in English tool-shops, and used by the Iroquois to generate fire. The Fuegians strike sparks with a flint from a piece of iron pyrites (Gr. *pyr*, 'fire') upon their tinder—a use which the etymology of the word shows to have been known to the ancients. The flint and steel must have come into use soon after the beginning of the iron age, but its origin in the civilised world is wrapped in the mists of antiquity. Among savage peoples it has made its way along with iron, but has often failed to supersede the fire-sticks. The use of the burning-lens to generate fire was known to the Greeks, and we are told by Plutarch was the method of solemnly reviving the sacred fire at Rome. The

last phase of fire-making—by lucifer matches—is fast making even the fire-sticks of the South African savage mere curious relics of the past. A strange survival of the ancient methods is the fire-churning still used in India for kindling the sacrificial fire, and the kindling by *wild-fire* alone of the English *need-fire* and German *Notfeuer* through which cattle were driven to avert pestilence down to the 19th century, in spite of the constant opposition of the clergy. The Easter and Midsummer-eve bonfires, so closely connected with ancient sun-worship, were tolerated and even adopted by the church, but the need-fire was disallowed by Rome; while in Russia, on the contrary, it seems to have been practised under the direct sanction of the parish priests.

The religious history of fire is even more obscure than the history of its production, although everywhere we find that a rich mythology has gathered round the subject. Like all the chief manifestations of natural forces, fire was early personified and worshipped, and we see a similar process of personification and divinisation in the names of the first fire-givers—the Greek Prometheus, the *pra-mantha* of the early Aryans, and in his Chinese parallel *Suy-jin*. The god of fire possesses generally capricious and variable qualities, as in *Loki*; now severe and cruel like *Moloch* and *Xiuhtecutli*; now beneficent like *Hestia*, *Agni*, *Atar*, *Ptah*, and *Baal Hamman*. We find among the Greeks, the Phœnicians, the Egyptians, Slavs, and Mexicans the co-existence of several fire-gods who personify respectively the diverse functions of fire; in the Vedas, on the contrary, we have the notion of the identity of *Agni* alike in the fire, the sun, and the lightning. Again, the essential identity between life, and fire visible in the sky but latent in everything, is an elemental idea among Romans, Hindus, Persians, Slavs, and Red Indians alike. The phenomena of generation are assimilated to the production of fire, whence fire becomes regarded as the author of life, and its worship is appropriately associated with phallic rites. The human soul is of the nature of fire; and fire, the common element of gods and of their creatures, of beings and things, becomes the soul of the universe, and plays a cosmic rôle as universal creator—a conception as akin to the philosophic mind of Zeno as to the primitive worshippers of *Ptah* and *Agni*.

Fire has ever been regarded as the great purifying element *par excellence*, not so much from its devouring properties and its incorruptibility as from its power as the dispeller of the demons of darkness. Hence the universality of belief in its power over evil spirits, and the use of lighting fires upon tombs, as well as of ordeals by fire—a pure agent which cannot harm the innocent. Fire puts to flight specially the spirits which cause maladies, whence the philosophy of magical cauterisation, and of the *need-fire* spoken of above. Fire again is considered as the heavenly mediator, which descends in thunder and remounts in flames, devouring the offering and thus answering the prayers of the priest. From this follows naturally *pyromancy*, the interpretation of oracles by fire, and hence the religious character of the cremation of the dead, seen in the outward act of the apotheosis of a Roman emperor. Lastly, fire is considered as the protector of collective existence, whence the perpetual fires of the Roman Vestals, the ancient Peruvians, Mexicans, the Damaras, and the like. Fire was carried by ancient Greek colonists from the sacred hearth of the mother-city, and is still the symbol of union among the red-skins of North America. See Tylor, *Researches into the Early History of Mankind* (1865); Kuhn, *Die Herabkunft des Feuers und des Gotterkinks*

(2d ed. 1886); Goblet d'Alviella, *Histoire Religieuse du Feu* (1887); W. Wachter, *Das Feuer in der Natur, im Kultus u. Mythos*, &c. (1904); Bidwell, *History of Fire-making* (1912); also BELTANE, ORDEAL, PARSEES, ZOROASTER.

For physics and chemistry of fire, see COMBUSTION, FLAME, HEAT, LIGHT; see also ELECTRICITY, FRICTION, FUEL. Forest fires and prairie fires occur in some regions very frequently, and are often rapid in their progress and most destructive.

FIRE-BRIGADE—The first fire-brigade on professional lines was founded in Edinburgh in 1824, when the police commissioners and the principal insurance companies combined and formed the Edinburgh Fire-engines Establishment, under the management of James Braidwood (1800-61), who was appointed Master of Engines. He organised the fire establishment on such efficient methods that his system soon became the model for similar organisations in all parts of the country. He introduced the first systematic method of saving life from fire by his invention of a chain ladder, which was suspended from the roof of a burning building, and enabled the firemen to descend to the floor affected and rescue the inmates. Braidwood introduced the first organisation of a body of men as firemen, and so complete and efficient was the system in Edinburgh that he was invited to go to London, which he did in 1833, and became superintendent of the London Fire-engines Establishment, an association formed and maintained by the principal fire insurance companies. Mr Braidwood was killed, whilst directing his men, at the great fire of Tooley Street, London, in June 1861. The insurance companies' fire establishment existed in London until January 1866. Under an act of parliament of 1865 the Metropolitan Board of Works took charge of the fire establishment and fire protection of the Metropolis, Captain E. M. Shaw, who had succeeded Braidwood, being the chief officer. In 1887, when the London County Council came into existence, the London Metropolitan Fire-brigade was taken over by that body. The personnel of a fire-brigade varies in different localities. Braidwood recruited his men in Edinburgh from slaters and house-carpenters; previous and subsequent to his appointment in London, the firemen were recruited from amongst the Thames watermen. Captain Shaw found sailors made the best firemen, and during his tenure of office as chief of the London Fire-brigade none but sailors of either the navy or the merchant service were engaged. In Glasgow the firemen are principally slaters and house-joiners. In Paris the fire-brigade is composed of a regiment of engineers lent by the government to the municipality. The men engage for their period of military service, which they serve in the Paris Corps de Sapeurs-Pompiers. Only a small percentage re-engage for permanent service, to become experienced firemen. In Berlin the brigade is composed of time-expired soldiers, who are permanently employed. In New York, Chicago, and most American cities the firemen are recruited from all ranks of workers. Owing to the introduction of more mechanical appliances than heretofore, men with mechanical knowledge are now largely employed in the fire service; but the seaman still proves to be the best all-round man.

Fire-engines.—Previous to the beginning of the 19th century practically no organised attempt was made by any authority in the country to deal with the extinction of fire. By an act of Queen Anne, 1708, each parish in London was required to maintain two 'fyre engines' and ladders out of the rates; this was the introduction of the 'parish engine', which was under the control and management of the parish beadle. At the great fire of London,

1666, the only known 'fyre engine' was a brazen hand-squirt of cast-brass, 30 inches long, which was operated by three men, two holding the squirt by side handles, whilst the third man withdrew the piston, drawing the water in from a leather bucket; the discharging point of the squirt was then raised towards the burning building and the piston pushed in, driving the water out. This 'fyre engine' was the only provision existing to deal with the great fire, its progress being arrested by the efforts of the military, who pulled down the buildings. In the year 1667, following the great fire, the Common Council of the City of London directed that the city should be divided into four districts, each of which was required to provide, 'for the preventing and suppression of fires in the future, brazen hand-squirts and leather buckets.' In 1698 the Hand-in-Hand Fire Office appointed a number of 'firemen' from amongst the river Thames watermen; this is probably the first introduction of the word in this sense. (As gunner or soldier, and as stoker of a furnace, the use is older.) In 1714 Gay, in his *Trivia*, says: 'The fire-man sweats beneath his crooked arms.' In 1703 the city council of Edinburgh passed an act 'appointing a Company for quenching of Fire, and Rules to be observed by the Inhabitants thereanent.' The council decided to appoint twelve firemasters, each of whom should have six assistants to himself. There were, however, no engines provided, the only appliances mentioned being, for each firemaster, a baton, a leather hat, buckets, six shovels, and six mattocks.

In 1672 Van der Heide, Dutch engineer and artist, had a well-organised company of firemen in Holland; he made the first manual fire-engine and flexible leather hose. Previous to the introduction of the flexible hose by Van der Heide, the directing pipe or nozzle was fitted on the top of the engine on a swivel elbow, the fireman directing the water from the top of the engine, which was taken directly in front of the burning building. During the 18th century the work of fire extinction was almost solely undertaken by the fire insurance companies. Each company maintained its engine and company of firemen to protect its own property. When an insurance was effected on a building, the company affixed its 'fire-mark' on the building 'to prevent any fraud in getting any policy by indirect means after a house is burnt. No house is to be esteemed a secure house till the mark has been actually affixed thereon.' The insurance companies' body of uniformed firemen were known by the name of the fire-offices to which they belonged. In 'Rejected Addresses' (1812) on the burning of the old Drury Lane Theatre some verses describing the fire ran:

Then jacket thick, of red or blue,
Whose massy shoulder gave to view
The badge of each respective crew
In tin or copper traced.

The engines thundered through the street,
Fire-hook, pipe, bucket, all complete;
And torches glared, and clattering feet
Along the pavement paced.

The 'Hand-in-Hand' the race begun,
Then came the 'Phoenix' and the 'Sun,'
Th' 'Exchange,' where old insurers run,
The 'Eagle,' where the new.

As has been said, in most modern British fire-brigades the men are recruited from all classes of mechanics and tradesmen, whilst a large percentage are seamen. In this manner several brigades have fully equipped workshops wherein the men work at their particular trade or calling in making and repairing the fire engines, ladders, fire-escapes, and other plant; this system is not only economical, but it admits of repairs being expeditiously executed on the spot. The manual fire-engine introduced by

Braidwood in Edinburgh was built by Tilley of London in 1824, and required forty men to work it. When worked at full pressure—viz. about forty strokes per minute—it delivered approximately 140 gallons per minute, at 60 lb. pressure, through two lines of hose with $\frac{3}{4}$ -inch nozzle or jet on each, giving an average altitude for each jet of 65 feet.

Steam Fire-engines were first used in a practical form in 1860 in London. One built by Shand Mason was hired by the London Fire Establishment for two years before being purchased by the authorities. The weight was three tons. It was a horizontal engine of one cylinder, and had a pumping capacity of 150 gallons per minute. The modern fire-engine, known as the 'steamer,' usually has a pumping capacity of either 350 or 450 gallons per minute. In the horse-drawn engine the power and pumping capacity of the fire-engine is limited by the energy two horses are able to exert in taking the engine at a rapid pace to a fire. An engine of a pumping capacity of 450 gallons per minute weighs, when loaded with eight firemen, 3 tons 5 cwt. The boiler is water tubular; the tubes are $\frac{3}{4}$ inch internal diameter, and are arranged in rows horizontally, slightly inclined to assist circulation. In the boiler of the 450-gallon size engine there are 160 tubes, affording, in addition to the walls and crown of the boiler, a large steam-generating surface. When the engines are standing in the fire-station the boilers are usually heated by means of steam from a stationary circulating boiler, or a gas-ring placed inside the fire-box. The fire is ready laid, and steam should be raised within from four to five minutes after lighting up. The working steam-pressure is 140 lb., and this pressure should be available by the time the engine has reached a fire and the hose has been laid out ready for work. The engine has two steam-cylinders direct double acting on the pump. The pistons of the steam-cylinders have each two piston-rods passing on either side of a double-throw crank-shaft, and are connected to a crosshead on the pump-rod; from a joint on the crosshead a connecting-rod returns to the pin of the crank-shaft. The cranks being at right angles, the engine may be started from any position. Eccentrics are fitted at the outer ends of the crank-shaft, where are also light-weighted solid fly-wheels about 10 inches diameter. To ensure steady discharge the delivery side of the pump is fitted with a capacious air-vessel. The suction-tube is 5 inches diameter, and connections for four delivery-hose are provided. The altitude and number of the jets depend upon the size of nozzle employed. The following table gives the average altitude of a fire jet or stream under normal atmospheric conditions:

Pumping Capacity of Steamer.	One Delivery.		Two Deliveries.		Three Deliveries.		Four Deliveries.	
	Diameter of Nozzle.	Height in Feet.	Diameter of Nozzle.	Height in Feet.	Diameter of Nozzle.	Height in Feet.	Diameter of Nozzle.	Height in Feet.
260 gallons	1 in.	100	1 in.	100	1 in.	70	1 in.	—
350 "	1 $\frac{1}{4}$ in.	100	1 $\frac{1}{4}$ in.	80	1 $\frac{1}{4}$ in.	80	1 $\frac{1}{4}$ in.	60
450 "	1 $\frac{1}{2}$ in.	120	1 $\frac{1}{2}$ in.	110	1 $\frac{1}{2}$ in.	100	1 $\frac{1}{2}$ in.	70
450 "	1 $\frac{3}{4}$ in.	130	—	—	—	—	—	—

Fire-nozzle.—The nozzle or nose-pipe forms the most important factor in the equipment of a fire-engine. It is used to determine the diameter, altitude, and efficiency of the water-jet or fire-stream. The internal bore of the nozzle requires to be most accurately finished, the surface free from irregularities or scratches. The most minute scratch on the inner surface at the edge of the lip of a nozzle will break the water-column at that point, causing it to spray. The object of the nozzle is to produce

a continued, smooth, solid column of water for as great a length from the discharging nozzle as possible. The continuity and solidity of the column of water depends upon the resistance due to the atmospheric conditions. The most favourable conditions are a calm, still atmosphere in which the column of water is only broken by the resistance it makes owing to the velocity with which it passes through the air, and, secondly, by its own weight in breaking away when the velocity decreases as the water reaches the maximum altitude. It is impossible to determine accurately the length a vertical or a horizontal jet of water will attain as an effectual fire-stream owing to the above conditions, the governing factor always being the force of the wind. The following table is taken from *Experiments relating to Hydraulics of Fire-Streams*, published in the United States by J. R. Freeman. The figures are for jets from nozzles of the ordinary fire-brigade working diameters, through 100 feet of ordinary canvas hose of 2 $\frac{1}{2}$ inches diameter, working under ordinary conditions. Column V shows the vertical and column H the horizontal effective striking distance:

Pressure at Pumps in lb. per square inch	1"		1 $\frac{1}{4}$ "		1"		1 $\frac{1}{4}$ "		1 $\frac{1}{2}$ "		1 $\frac{3}{4}$ "	
	V	H	V	H	V	H	V	H	V	H	V	H
40	55	41	54	45	58	42	36	38	37	40	29	33
50	64	47	67	56	68	51	50	50	40	42	34	35
60	67	50	72	60	70	55	59	55	48	47	47	42
70	72	54	75	62	74	60	68	59	57	55	55	49
80	76	58	77	65	80	64	76	66	71	63	67	56
90	79	62	82	68	86	69	84	69	82	70	80	59
100	80	64	90	72	94	73	94	75	100	76	91	62
120	88	68	95	79	97	79	100	79	107	84	110	78
140	—	—	—	—	105	82	109	85	112	86	118	90

Each particular diameter of water-jet reaches its maximum altitude under a certain pressure. If the pressure is increased beyond that particular point, the jet meeting with greater air-resistance breaks at the point of leaving the nozzle, and the altitude is greatly diminished. The maximum pressures giving best results are: $\frac{3}{4}$ inch, 100 lb.; 1 inch, 110 lb.; 1 $\frac{1}{4}$ inches, 140 lb.

Hose-box and Gear Carried.—That portion of the fire-engine which forms the seat for the fireman is known as the hose-box; in it are carried several hundred yards of hose, branch-pipes, nozzles, stand-pipes, hand-pump, canvas buckets, life-lines, hauling-lines, canvas dam or cistern, jumping-sheet, saw, large felling-axe, cold-chisels, hammer, &c.

Automobile Fire-engines were introduced by Merryweather of London, and first came into general use in 1894. They are propelled by steam, the boiler being of the ordinary quick-steaming tubular fire-engine type, fired by oil fuel. The engine consists of two steam-cylinders driving a crank-shaft with link motion reversing gear. The crank-shaft is geared on to a counter-shaft driving two chain sprocket wheels which are connected to the rear road-wheels by steel roller chains. The pumps are placed below the crank-shaft, directly under the steam-cylinders. The pump-pistons, being provided with quick-action couplings, are thereby put into gear with the engine, which is thrown out of gear with the counter-shaft when the pumps are in use. There is accommodation for a large quantity of hose and other appliances. The speed of the engine is from 30 to 40 miles an hour. In order that the engine may be ready to start immediately for a fire, steam is maintained in the boiler by means of a stationary steam-heater boiler in the fire-station. These engines have pumps capable of delivering 500 gallons per minute at 140 lb. pump-pressure.

Petrol Motor-pumping Fire-engines, in general use in fire-brigades, are driven by engines of the heavy commercial vehicle type, having four or six cylinders of 50 b.h.p. or six cylinders of 75 b.h.p. The average

speed is 35 miles per hour, and the pumping capacity is 350 gallons per minute driven by the 50 h.p. engine, and 600 gallons per minute driven by the 75 h.p. engine. There are two types of pumps fitted to the petrol motor fire-engines—viz. the piston or plunger pump, and the centrifugal or turbine pump. The plunger-pump, which requires to run at a low speed—250 revolutions per minute—consists of three pump-barrels in one casting in triangular form, the pump-pistons being driven by a single crank on a shaft running through the centre of the pump-casting, each pump-rod being coupled on to the crank-pin. Each revolution of the crank makes one stroke for each pump-piston. The pump crank-shaft is driven from the motor by means of a silent chain gearing from the first motion shaft through the gear-box. This pump is known as the 'Hatfield' type of reciprocating pump. The centrifugal or turbine pump consists of a centrifugal pump of one or more stages, geared up from the motor to run at speeds varying from 1000 to 2000 revolutions per minute. One of the features of this class of pump is that, the centrifugal pump being unable to create a vacuum, it cannot lift water; consequently a reciprocating air-pump is fitted to the engine, being driven by a separate friction clutch or gearing from the main-pump shaft of the petrol motor. When the pump is required to be brought into operation, the air-pump is first started to create the necessary vacuum in the suction-pipe to bring the water to the level of the main centrifugal pump. When this has been accomplished the main pump is put into gear by engaging the pump clutch on the main shaft. Petrol motor-engines operate through one or more lines of hose as circumstances may require. A 600-gallon capacity engine will give its highest efficiency at a high altitude through one line having a 1½-inch nozzle, two lines having each 1-inch nozzles, three lines having ¾-inch nozzles, or four to six lines having ½-inch to ¾-inch nozzles. These engines may be operated to pump through 500 to 600 yards of hose, but the longer the length of hose the greater the loss of pump efficiency due to the friction of the water against the walls of the hose.

Hose-tender.—The hose-tender is used in fire-brigades as a vehicle to carry hose, ladders, and general appliances for use at a fire. Being of lighter weight than the fire or pumping engines, it is able to accommodate a larger quantity of appliances and a greater number of firemen. This vehicle is known in America as the 'hose and ladder truck'.

Electric traction for fire-brigade vehicles has been adopted by some British brigades, but is restricted by limited output of portable storage-batteries. The average maximum mileage obtained with a heavy motor vehicle from one set of batteries is 40 miles. The power is thus limited to propulsion, and is not available for pumping-power. In some large cities on the Continent electric-power for traction is largely used for hose-tenders and fire-escapes. Steam pumping-engines are also mounted on an electric chassis, the steam-boiler being used to supply the power for the pump.

Hose.—There are three descriptions of fire-hose in general use—viz. leather, plain canvas, and canvas with a lining of rubber. Until 1880 leather hose was almost exclusively used from the time of its introduction. It was introduced or invented by the Dutch engineer Van der Heide in 1672. It was the first flexible hose used, the strips of leather and joints being sewn together. About 1820 the joints and seams in the leather were riveted together by copper rivets; and this method is still adopted. Leather hose has almost entirely gone out of use for fire-brigade work, but is still largely used on board ship in the navy and H.M. dock-yards. Canvas hose having a rubber lining is used

by some brigades, principally owing to the absence of percolation or sweating along the hose when under pressure. Plain canvas hose is woven from the best quality flax of about twelve yarns to the inch in the weft or horizontal yarn, and fifteen yarns to the inch in the warp or longitudinal yarn. Well-made hand-woven canvas hose will stand more hard wear than any other kind of hose, and is more easily repaired. It requires, however, very careful treatment after use; it must be thoroughly cleansed and carefully dried. The average life of a length of hose for fire-brigade work is ten years, and the average cost of plain canvas 2s. 6d. per yard. The hose in general use varies in diameter from 2 to 3 inches, 2½ and 2¾ inches being most generally used. The diameter of hose is an important factor in effective results of the water-delivery of the fire-engine, considerable loss of pressure being due to friction.

8-inch diameter hose	absorbs 60 per cent. less by friction than 2½-inch hose.
2½-inch diameter hose	absorbs 40 per cent. less by friction than 2½-inch hose.
2½-inch diameter hose	absorbs 20 per cent. less by friction than 2½-inch hose.
2½-inch diameter hose	absorbs 30 per cent. more by friction than 2½-inch hose.
2½-inch diameter hose	absorbs 70 per cent. more by friction than 2½-inch hose.
2½-inch diameter hose	absorbs twice as much as 2½-inch hose.
2-inch diameter hose	absorbs three times as much as 2½-inch hose.

The loss due to friction is greater in unlined or plain canvas hose than in either rubber-lined or leather. The comparative friction losses are: 30 per cent. in plain canvas hose; 25 per cent. in thin rubber-lined hose; 12 per cent. in leather hose; 10 per cent. in heavy rubber-lined hose. Plain canvas hose is one-fourth the weight of either rubber-lined or leather hose; it is more durable, of much less bulk, and consequently more compact for stowing away in the engines. It is also stronger than either leather or rubber-lined hose, and will stand an average pressure of 250 lb. to the square inch. For these reasons it has been found most suitable for fire-brigade purposes. Plain canvas hose costs one-third that of rubber-lined or leather.

Suction-hose requires to be flexible but non-collapsible. It is usually made of several plies of rubber and canvas, having embedded in the walls of the hose spiral steel wire to keep the walls rigid. The suction-hose must be very carefully made and treated; the slightest leakage on the suction-pipe would entirely disable an engine from drawing water from below the level of the pump. Any mixture of air with the water coming in from the suction side of the pump will cause the engine to work irregularly, and, instead of a steady, solid stream at the nozzle, produce a broken, intermittent, sprayed jet.

Fireplugs.—A fireplug is a conical wooden plug driven into a prepared socket in the street water-main. When the water is required for fire purposes, the plug is loosened by a lever, and the pressure of water drives it out. A stand-pipe with an open valve at the top and a tapered shoe at the foot is inserted in the pipe-socket and driven home, being secured by wooden wedges against the surface-box at the road-level. Fireplugs have been generally superseded by the fire-hydrant, which is enclosed in an iron surface-box on the footpath, and consists of a mechanical valve controlling the water-supply to one or two outlets, which are fitted with a connection to receive the hose or a connecting elbow direct. The water is always under the control of the valve. Another form is the ball hydrant. A special fitting is attached to the water-pipe having an outlet at right angles in the form of a globular box, which contains a vul-

canite or light solid rubber ball larger in diameter than either the water inlet or outlet. The pressure of water forces the ball up and closes the orifice. The special fitting at the road surface has a bayonet attachment which engages with the bottom of the stand-pipe, the latter having a screw-down spindle through its centre; and when the water is required the spindle is screwed down and depresses the vulcanite ball, allowing the water to flow round it and up through the stand-pipe.

Fire-escapes.—Fire-escapes vary in construction according to the requirements of particular districts. Ordinarily they consist of three-section telescopic ladders attached to a two-wheeled base, and carried on the motor fire-engine, from which they are detached and worked separately at the fire. This class of escape has a maximum extension of 55 feet. For higher altitudes mechanically operated ladders are fixed on a motor-propelled base, and are in four telescopic sections, carried horizontally on the motor-truck. When required to be brought into operation, the ladders are operated by a series of clutches driven by the motor-engine. The ladders are first brought up to a vertical position, after which they are extended to the required altitude and angle. These ladders, in addition to being used for saving life, are also used in fighting fire by directing water-jets into the upper floors of buildings. The ladders are extended in front of the building without requiring to rest against the walls for support. The fireman is then able to direct the jet of water from the top of the ladder into the building, the directing position being regulated by turning the ladder at the base to the desired angle. The maximum extension is 85 feet from the ground.

Scaling-ladders are short lengths of ladder about 7 feet each, carried on the fire-engines. Each length is fitted with steel sockets on the outside at the top end and on the inside at the bottom. The ladder is tapered, so that the top of one ladder will fit inside the bottom of the next, by which means several lengths are fitted together, making a ladder as long as may be desired. Hook-ladders, sometimes called 'pompiers' ladders, being a French introduction, are made light but strong, and are fitted at the top with a long hook at right angles to the sides of the ladder. One fireman is able to raise the ladder from the ground and hook it on to the window-sill of the first-floor window, pushing the hook through the glass. The fireman then ascends to the window-sill; standing there, he raises the ladder to the next window-sill above; and so on.

Jumping-sheets consist of canvas sheets fitted on the outer edge with a series of rope hand-loops. The sheets are usually 10 feet in diameter or square, and are stretched out and held taut by the hand-loops under the windows, from which persons to be rescued jump and are caught in the sheets.

Methods of obtaining Water.—Each fire-engine carries a collapsible canvas dam or cistern, which is supplied from a connection to a street hydrant. The water from the hydrant flows through an open bore and is collected in the cistern; the suction-pipe of the engine is put into the cistern, and the water is pumped out as fast as it flows in. Another method is to attach several connections from hydrants direct on to the suction-chamber of the engine, the pressure on the gravitation-supply thereby assisting the pumping-power of the fire-engine. This method of direct gravitation-supply cannot always be employed, being governed by the water-supply of the particular district. A third method of supplying the fire-engine is to draw direct from large reservoirs, rivers, docks, or canals by means of the flexible suction-pipe. The recognised all-round maximum vertical lift from the

level of the water to the pump is 25 feet, though petrol turbine-engines have been known, on official tests, by the aid of an air-pump on the suction-pipe, to lift water 28 feet.

Chemical Extinguishers are of American origin, and consist of small cylinders of 2 and of 4 gallons capacity. There are two types used for two general classes of fire. Of the first type, what is known as the soda-acid is in more general use. The cylinder is sealed, and is filled with a solution of bicarbonate of soda, and has lodged in a bracket a bottle of sulphuric acid. When the cylinder is required for use, the acid bottle is broken by the compression of a small piston, and the admixture of the acid with a soda solution causes the generation of carbonic acid gas, which is discharged through a $\frac{3}{8}$ -inch nozzle under a pressure of approximately 150 lb. to the square inch. There are no extinguishing properties in the liquid, the gas merely acts as the propelling power to discharge the solution on to the fire. The second of this type consists of a similar cylinder, in which the pressure is generated by a cartridge of carbonic gas or air which is punctured by the piston, the liquid being discharged by the air or gas liberated from the cartridge. These extinguishers are used for extinguishing fires of burning material, and are very effective in dealing with an outbreak of fire in the early stages, or to keep a fire in check while the larger appliances are being brought into operation. They are largely used for fire-prevention in private houses and public buildings.

For dealing with petrol fires and inflammable oils or spirits a different type of extinguisher has been found essential. Of the two kinds the first consists of small cylinders containing carbon tetrachloride discharged by a small double-acting pump, the piston of which is operated by being driven in and out in such a way that a tiny jet of the acid is projected on to the burning liquids or material. When the acid is in contact with fire it produces a heavy blanket of carbonic acid gas, which smothers combustion. The second extinguisher of this type consists of a cylinder discharging a foam or thick frothy substance, the bubbles of which are formed by carbonic acid gas. These are most effective for smothering fire on large surfaces or in tanks of oils or petrol. The foam is discharged into the tank, where it floats over the surface of the oil and smothers the fire.

'Fireproof' Construction.—The term 'fireproof' as applied to buildings has so far not yet been justified, as no known method of building construction has been proof against effects of fire. The use of fire-resisting building materials is no protection against the furnishings, fittings, fixtures, or stock of a warehouse taking fire. When the contents of a building take fire a great heat is often very suddenly generated within the walls; consequently the greatest strain upon the structure is to resist effects of sudden changes of temperature on the various metals and minerals forming the component parts of the building materials. Experience of conflagrations in various large cities in different parts of the world has demonstrated that no structural materials can withstand the chemical and physical effects of the great heat generated in an ordinary building on fire. Of all building materials sound timber has the advantage of being the best non-conductor of heat. If exposed to actual flame on all sides the timber will be charred and will slowly burn, but its solidity is not affected until it has almost burned through or at least until its stability has been seriously undermined; whilst properly bonded brick is the least affected of any of the harder materials, and has proved to be the most reliable under all circumstances and conditions of a conflagration.

Structural iron or steel work should be adequately protected successfully to resist the effects of the great heat generated, and it is because the stability of metal-work is seriously affected by the heat, without of necessity coming into contact with actual flame, that it is so much inferior to sound, solid timber, which is only affected when in a state of actual combustion. Well-burned brick of good quality, well laid in mortar, is the best protective covering known for steel and iron members and columns, and has the additional merit of adding to the stability of the structure. Stone is especially susceptible to damage when exposed to great heat. It is unsuitable, from a fire-resisting point of view, for either external work or column supports internally. This is very clearly demonstrated at the early stages of any fire to which it has been exposed; ornamental stonework is destroyed at the very early stages, and forms an element of danger and obstruction to the firemen when attacking the fire. Unprotected steel and iron work also fails at an early stage of a fire, and possesses the added disadvantage of pulling down the walls to which it is tied. Air-spaces in partitions and under floors should be rigidly excluded. Hollow partitions are not only readily destroyed, but form conduits conveying smoke and fire from one portion of the building to another. Large open areas assist the spread of fire, particularly in buildings having highly combustible contents; the larger the area the greater the intensity and severity of the fire. The fire-resisting construction of a building offers no protection in such a case. The report of the chief engineer appointed by the U.S. government on the great conflagration at Baltimore in February 1904 states: 'Stone of every description suffered severely, particularly projecting parts. Terra-cotta facings and ornamental work failed completely. Granite spalled [crumbled] badly, worse than any other stone under moderate heat. Marble spalled badly, but not so much as granite. Of all materials on external walls, properly bonded brickwork was the only thing that was really successful.'

The Fireproofing of Wood and Soft Materials.—The treatment of wood and fabrics by chemical solutions of various qualities renders inflammable materials flameproof, and so retards the spread of fire. It is not sufficient to treat the surface of wood only. The wood is placed in a huge cylinder, wherein the air and moisture are extracted by a vacuum-pump; after which an antipyrin, run in in solution, is forced into the open pores. In most theatres the scenery, draperies, &c. are periodically impregnated by a solution of one of the many chemicals, such as borax, boracic acid, salts of ammonia, &c., which tend to check combustion. The treatment of such materials will not prevent their destruction in a conflagration, but it will prevent the scenery from bursting into flame should it come in contact with a naked light or an electric arc, in which case the material would carbonise and burn very slowly at the point of contact only. See various lectures on this subject by Professor Vivian Lewis, of Birmingham University.

Fire-brigade Stations.—Fire-stations consist of a block of buildings in which are housed all the necessary appurtenances of a fire-brigade, including housing of the men with their families, workshops, stores, offices, gymnasium, drill-yard, &c. The engine-room—for horsed appliances—usually has accommodation for four or five engines, with stabling in the immediate rear of the engines. The horses stand in a stall facing the engines; the end of each stall is enclosed by a mechanically controlled door. On the ringing of an alarm the doors are opened either by automatic or electric contrivance. The horses are trained to run forward

and place themselves under the harness, which is suspended from spring clip-hooks above the pole of the engine. It is pulled down by one movement, and the horse stands harnessed and ready. Where the engines are automobiles there is of course no stabling. The engines, however, are on the same principle, each having a separate exit door, the engine standing immediately behind the door, ready to move forward when required. The firemen are housed above the engine-room and workshops, their bedrooms being connected with the electric fire-alarm installation. On the ringing of the alarm a light is put on in each bedroom. Simultaneously with the ringing of the fire-bell the men descend from their quarters on the upper floors by sliding down polished steel poles to the engine-room, where they find their fire uniforms and helmets, &c., mount the engines, and away. The average time taken to turn out a fire-engine in a well-equipped station is fifteen seconds by day and fifty seconds by night. Owing to the advances made in the introduction of mechanically propelled engines, one of the essential features of a fire-station is properly equipped workshops, wherein the necessary repairs to engines are expeditiously executed by the firemen.

Fire Prevention.—It is estimated that of the large number of fires which occur in domestic households quite 50 per cent. are due to carelessness, and may be guarded against by the exercise of a few elementary precautions in everyday life. Unprotected gas-jets near dressing-tables and windows are amongst the principal causes of fires. The lighted gas, being required for dressing, is often fitted beside a window which is opened to admit the air. On some one's leaving the room the opening and closing of the door causes a sudden draught to arise between the window and the door, and this draws the window-curtains on to the unprotected gas-flame, thus firing the curtain, which falls on the dressing-table. A gas-globe is a good preventive. Draperies round mantel-boards are similarly dangerous. If the drapery is loosely arranged, the draught from the open door will draw it towards the chimney and into contact with the fire in the grate. Draperies at fireplaces, if not entirely dispensed with, should be securely fastened at the sides to prevent their being blown about by draughts. The sailing of linen in front of open fires is the frequent cause of fire, the garments being usually hung on drying-horses, backs of chairs, or high fenders. When they are dry their weight causes them to slip or roll off, inside the fender, or even on to the burning coal; or sparks fly out on to the drying material. Wire fire-guards are a preventive against sparks; and if the clothing be securely fastened to the horses or the chairs, this will effectually keep it from slipping off on to the fire. Carrying live-coal in a shovel from the fireplace of one room to that of another room is also a very dangerous practice. A small piece of burning coal falling from the shovel on to the carpet or the clothing will instantly set it on fire; and in the endeavour to extinguish it the shovel with the remainder of the burning coal is usually dropped, causing at once, it may be, a serious outbreak. Lighted tapers are the frequent cause of domestic fires, owing to carelessness on the part of the person carrying the taper or the candle in lighting up the gas throughout the house for the evening, or when using a lighted taper as a means of illumination at linen-presses, clothes-closets, and the like. Searching for domestic pets under beds and tables with this form of naked light is naturally very apt to set the bedding or the clothing on fire.

Benzine, methylated spirit, petrol, and other highly volatile spirits used for cleaning purposes in close proximity to naked lights or open fires are all of them highly dangerous. The spirit vapour is

wafted about the apartment by the ordinary currents of air, and should the vapour become ignited flame will follow to its source in the cleaning material, with serious consequences. In the case of gas-escapes, explosions can be avoided if care be taken to avoid the use of artificial lights and to empty the house or apartment of the gas. If the presence of the gas interferes with breathing, cover the mouth and nose with a damp cloth, handkerchief, or towel, proceed through the house from the bottom *without a light*, and open the window in every room—up from the bottom and down from the top—allowing the air to enter from the bottom of the window and drive the gas out at the top. No room or cupboard should be left unopened; and it should always be remembered that the gas will be strongest on the top floor and in the attics. Turn off the gas at the meter or the main as soon as possible; and after the house is free from gas and the supply of gas is turned on again, the defect will be easily detected by the smell at the point of escape. Cotton-wool when used for decoration purposes is highly inflammable; and particularly when it is applied to clothing, its use exposes the wearer, should the wool become ignited, to almost certainly fatal consequences. Many serious disasters have been caused by the use of cotton-wool for the above purposes. Silicated cotton is a good substitute, and has a glistening effect when exposed to artificial light. Silicated cotton is impervious to the fire.

Celluloid is another highly inflammable and dangerous commodity which is used largely for decorative articles of wearing apparel. Persons wearing or using celluloid combs should avoid the use of heated curling-tongs. Celluloid will burst into flame at a very low temperature, and does not necessarily require to be in contact with actual flame before igniting. Any article of wearing apparel of this substance should be considered as an element of danger.

Cleanliness and tidiness are essential. Many fires are due to the litter about the floors of workrooms, untidy store-rooms, packing materials, rubbish in cupboards, coal-cellars, &c., all of which are ready for the carelessly thrown or dropped lighted match.

Firearms. The generic term 'firearm' includes Cannon, Rifles, Guns, Revolvers (q.v.), and other weapons in which an explosive is used as an agent for the propulsion of projectiles. Their early history is inseparable from that of Gunpowder (q.v.), and most improvements in firearms have coincided with some development of gunpowder or the discovery of fresh explosive agents. The earliest firearms were probably merely cases for burning highly inflammable mixtures; then something akin to gunpowder was used to propel other less combustible portions of the filling from the case; and still later the mixture was fired simply as the propellant of a stone or weapon.

The knowledge of gunpowder and firearms may be presumed to have extended in a westerly direction through the Arabs, who used them in the 8th century under the name of 'manjaniks,' and introduced them into Spain in the 13th century. Seville was defended in 1247 by cannon throwing stones, a cannon in the castle of Concy is marked in Arabic figures as having been made in 1258, firearms were used in the defence of Melilla (1259) and at the siege of Sidgil-Messa (1273), and a 'fire-mouth' was made at Amberg in 1301. The English are said to have used firearms at D'Eu in 1310, but the first mention of them in a contemporary record occurs in an indenture of 1338 of the equipment of the king's ships of 'ij canons de ferr . . . un hand-gone . . . barell de gonpouder.' A little later such words as 'gonness,' 'gunnis,' and 'bombardes' appear

in records; whilst Chaucer (1373) mentions 'gonne,' and Barbour (1375) that 'crakys of wer' had been used at Werewater in 1327.

In Europe the early firearms range in size from the small cannon as used at Crécy (1346) and Rouen (1388) to siege weapons of great size, as that sent to Orleans (1428). Cannon were cast at Augsburg in 1378, but in England not until about 1535. In the 15th century many German towns possessed big guns, and the reputation of these weapons sufficed to protect cities from ordinary assault. Mahommed II. procured a gigantic gun to besiege Constantinople. Whilst cannon might be used for sieges and defending fortified strongholds, their general use in battle was regarded as ignoble, and as weapons they were counted of little worth. The English conquered France with the longbow in the 14th century, and early in the 15th were driven out by firearms.

Different countries had different names for these early firearms—in Italy 'bombardo,' in France 'quenon,' in Germany 'buchsen,' in the Netherlands 'vogheleer,' in England 'crackeys' or 'engynnes' of war; but it was not until the 15th century that firearms were classified and named accordingly. *Bombards* were short, capacious vessels, from which stone balls were shot with small charges to a short distance and at considerable elevation; they were essentially the parents of the present bombs or mortars. The *cannon* (*canna*, 'a reed'), on the other hand, were, for some time at least, of extremely small bore, scarcely larger than muskets of the 18th century; they discharged leaden bullets, and would have probably been used as hand-weapons but for their cumbersome and heavy workmanship, which necessitated small carriages. Arms of this description are doubtless those referred to as having been brought by Richard II. to the siege of St Malo, to the number of 400 pieces, where they are said to have kept up an incessant fire day and night on the town *without* success.

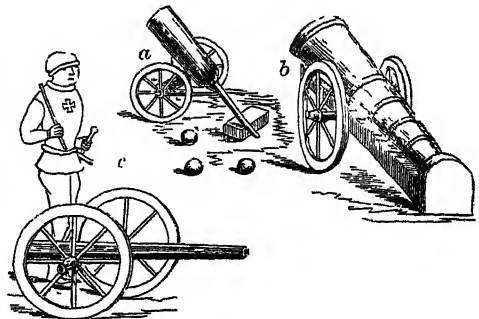

Fig. 1.

a (from the *Chroniques de St. Denis*), 14th century; b, bombard of the 15th century (from Froissart); c, cannon of the 15th century (from *Les Vigiles de Charles VII.*).

All these early firearms were usually loaded to the muzzle, and fired at an extreme angle. Charles V. classed mortars separately, mounted cannon upon carriages, added trunnions, and effected other improvements in his artillery, which consisted of cannon; great, bastard, and small culverins; falcons and falconets. The classification of firearms led to the development of various types to be used for specific purposes, and an invention which effected a great improvement to one type was useless or inapplicable to another. Cannon of 120 tons and pocket-pistols of 4 ounces, although they have a common origin, have not a common history. Cannon were of wrought iron, built up

by the handicraft of the smith, of rods and rings, and were used as they left his forge. Cannon of a copper and tin alloy were cast at Augsburg in 1378; they have since been made of hollowed blocks of stone; or cylindrical holes, bored in the solid cliffs, have been used to fire projectiles, as at Alexandria, Constantinople, and Gibraltar; they have been made of wood, of rope, of leather, and of papier-maché, as well as of almost every pure and alloyed metal it is possible to cast or forge. The early cannon were chiefly used at sieges, as their weight and the badness of the roads, added to the inefficiency of the weapons themselves, precluded their advantageous use as field-pieces, and if utilised in a pitched battle they were fired but once. But on the one hand the development of cannon into small portable weapons produced hand firearms, and on the other the increase of size and weight led to the large weapons so important for the defence of fortifications. Of this type the 'Mons Meg' of Edinburgh Castle is an early specimen; it weighs nearly 4 tons, and fired a stone shot of over 300 lb. The powder-chamber is of a less diameter than the bore of the cannon, in this particular resembling the mortar, and exhibiting the reverse of the principle of enlarged powder-chamber now employed. Such cannon were made at Ghent in the 15th century.

The culverin, a useful size of cannon, was employed generally in England until after the Commonwealth. Culverins fired stone shot, iron

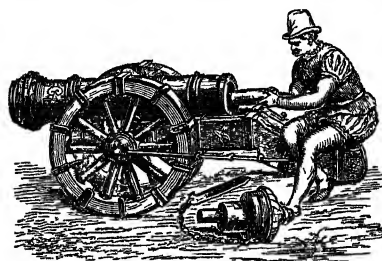

Fig. 2.—German Breech-loading Cannon of the 16th century.

balls, leaden bullets, and composite projectiles—a leaden jacketing being cast round uneven stones to make them heavier, and the better to fit the interior of the cannon. Such cul-

verins and projectiles were made by the blacksmiths of Deritend, Birmingham, in the 17th century, and were used at the battle of Worcester. Field-pieces were not greatly developed until the 18th century, when the improved finish of the interior allowed of long and uniform ranges, and a certain definite accuracy being obtained. The breech-loading field artillery are now of a high degree of excellence; but whether firing shot or shell the limit of power will be found in recoil, as is the limit of accuracy in the correctness of the aim.

For defensive purposes, as well as for certain offensive operations, special arms were required and constructed: of these the long-barrelled wall-pieces for defence; the 'petard,' and mortars firing bars, oblong and square bullets, for making a breach; explosive shells and grenades for clearing a trench; grape and chain shot for mowing down compact squares of infantry or destroying the rigging of battle-ships, are the best known. From the 'orgue de bombardes,' another type of early firearm, the quick-firing, many-barrelled machine guns have been developed. The earliest form of this weapon is the 'ribaudequin,' of Italian origin, which consisted of a number of small cannon and pikes arranged upon a portable carriage; it was fired but once during an engagement, and was primarily intended as a defence against a cavalry charge. The 'orgue de bom-

bardes' (fig. 3), with more cannon (fired simultaneously) and fewer pikes, succeeded the ribaudequin.

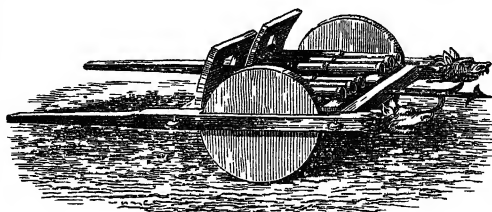

Fig. 3.—French Orgue des Bombardes.

Further developments survived into the era of percussion firearms.

With the cannon and quick-firing machine guns, the improvements have depended less upon the ingenuity of inventors than on the achievements of mechanical science to accomplish accurate workmanship, and work great masses of material as skilled workmen can handle smaller pieces. The improvements in explosives, in the quality of the metal, and in the machinery available, have rendered possible the production of such immense weapons, that the limit of size would appear to be rather in the cost of manufacture and the enormous expenditure risked upon the aim, than in the inability of modern mechanicians to produce still larger and more powerful weapons (see CANNON).

The development of the hand firearm, on the contrary, called for the ingenuity of the handicraftsman, and at first this ingenuity was exercised in the combination of a firearm concealed with some other weapon, so that its firing unexpectedly

Fig. 4.—Pistol Battle-axe.

should produce a consternation; and for the same reason repeating and double-barrelled weapons were produced. Firearms were incorporated with daggers, swords, pikes, clubs, maces, axes, and shields; and it was the use of these devices by cunning warriors that disgusted the knights and led to their loss of prestige, and hastened the decay of feudalism. The hand firearms owed their success quite as much to the consternation caused by their unexpected discharge as to the execution done by their projectiles: hence Montaigne wrote in 1585, when the muskets in use were much superior to the earlier culverins, that their effect, apart from the shock caused by the report, was so insignificant that he hoped the use of them would be discontinued. It was as a surprise weapon that Neapolitan brigands and French postillions were armed with whips, the handles of which were cunningly devised and well-hidden pistols.

The culverin or hand cannon was a small tube of $\frac{1}{2}$ or $\frac{3}{4}$ inch internal diameter, fixed to a straight piece of wood or welded to an iron handle. At the close of the 15th century they were extensively used. In 1471 culveriners were in the army of Edward IV. after his landing at Ravenspur, Yorkshire; and hand firearms were used at the siege of Berwick in 1521. The smallest hand-culverins—about 4 feet in length and weighing 15 lb.—were used on horseback; heavier weapons up to 60 lb. weight were used

by the foot-soldiers. The culveiner was attended by a 'varlet' to aid in firing the piece, which was always supported upon a forked rest. The arquebus

Fig. 5.—Early Hand-culvein.

was a smaller and improved culvein, requiring but one man. Grose writes of the equipment of the culveriner: 'He had, in addition to the unwieldy weapon itself, his coarse powder, for loading, in a flask; his fine powder, for priming, in a touch-box; his bullets in a leathern bag, with strings to draw to get at them; whilst in his hand were his musket-rest and his burning match.'

The touch-hole of the culverin was in late patterns placed in the side, instead of on the top as with cannon, a flash-pan was added, and early in the 16th century the serpentin or lever to hold the burning match was invented, and the matchlock quickly followed. In the best matchlocks the flash-pan was covered with a hinged lid, and the serpentin was forcibly thrown upon the touch powder in the flash-pan by a spring; but in the ordinary types the burning slow match was made to descend by pulling the lower end of the serpentin towards the stock. From the matchlock arquebus came the hagbut, hackbutt, hackenbuse, and the musket, which was originally a heavier weapon, and carried a double bullet. These early firearms were loaded with difficulty; at Kissingen in 1636, and at Wittenmergen in 1638, the musketeers fired seven shots in eight hours, which is accounted for by the fact that musketeers were harassed by the opposing cavalry

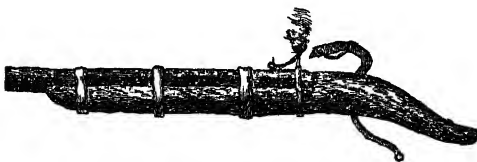

Fig. 6.—Early Matchlock-gun.

and archers, and that the loading had to be effected whilst the forked-rest was attached to the wrist by a short thong, and the soldier 'in skirmish doth charge his musquet afresh, and train his forke or staffe after him.' The matches of slow burning fuse, even when carried in the hat, or in a perforated metal case at the girdle, gave much trouble, especially in wet and foggy weather, and at the battle of Dunbar (1650) the English musketeers were unable to retain their fire on account of the weather. The *wheel-lock* originated from a gun in which pieces of pyrites were placed near the flash-pan, and the igniting spark was produced by the friction of a file rubbed against them. In the wheel-lock the flint is held in the flash-pan by a spring pressing against the opposite extremity of the lever to the one in which the flint is fixed; in the flash-pan is a grooved wheel with serrated edges, which is rapidly rotated by a chain and flat or V spring, or as is the drum of a watch. The wheel was wound up as in a watch, with a movable key, and was released upon the trigger being pulled; its rapid rotation against the flint firmly pressing upon it produced a stream of sparks instantly, and made ignition more certain. The wheel-lock was invented at Nuremberg in 1517, used at the siege of Palma (1521), introduced into England in 1530, and soon firearms were used for sporting purposes.

The *firelock* or flintlock, more common than the expensive wheel-lock, was produced in Spain about 1625, as a cheap substitute for the wheel-lock. In the flintlock the *hammer* or cover-plate to the flash-pan is knocked backwards by the blow of the flint screwed in the jaws of the *cock*, and, uncovering the pinning in the flash-pan, exposes the touch powder to the sparks produced by the flint grating against the steel face of the hammer. The early flintlock was clumsy, simple, and inefficient; it is said to have been produced by marauders, to whom the burning match of the arquebus was dangerous as betraying their presence; and, roughly made, it did not answer as a military weapon so

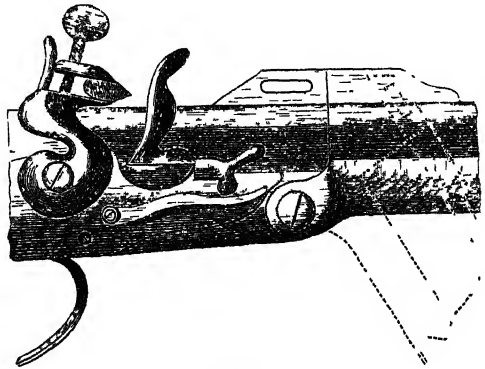

Fig. 7.
French Flintlock Breech-loader, 18th century.

well as the matchlock. Improvements in the latter half of the 17th century caused its more general adoption. It was common in the Netherlands, and was introduced into the English army in the reign of William III., and remained in use until 1840; the last firelocks supplied to the British government were for use abroad, and were made in 1842. The firelock or flintlock musket is still an article of commerce, as it can be used wherever there is a supply of powder and lead. The flintlock in its highest degree of perfection was manufactured in London as a double sporting weapon at the beginning of the 19th century.

Pistols were developed from the small hand cannon termed 'poitrinal,' and were made in 1540 by Camillio Vittelli at Pistoia. They were used as *concealed* weapons, the German Ritters being the first to adopt them for military purposes. At the battle of Renty in 1554 the Ritters defeated the French through a manœuvre termed 'caracole,' in which the pistols played the most important rôle. The pistols, from having short barrels and heavy, clumsy butts, improved into successful cavalry arms when furnished with wheel-locks, and they were generally adopted as an auxiliary weapon. Double and four-barrelled pistols were common in the 18th century, and the revolving pistol, termed the 'pepper-box,' preceded the introduction of the modern revolver by Colonel Colt (see REVOLVER).

As a triumph of handicraft and exact workmanship the duelling pistol is without a rival, and the twenty-pace pistols firing a large bullet with a small charge of powder, as made in Paris at the present time, are not to be equalled as weapons of precision by any firearm extant. The revolver has superseded the pistol entirely for military and police purposes in civilised countries, but the revolver will in its turn have to make way for a magazine or repeating pistol.

Many of the early cannon hand-forged from rings and bars were breech-loading, the system employed being that of the movable breech-block,

secured in position during the discharge by hammer-driven wedges; or a through pin uniting the block with the breech frame of the cannon. Such weapons date from the 14th century, and similar weapons formed part of the equipment of the *Mary Rose*, which foundered about 1545. Small-arms intended for the use of illustrious persons were occasionally made breech-loading. In the Tower collection is a musket which closely resembles the modern Snider in its breech mechanism, and this remarkable specimen of an efficient breech-loader is said to have belonged to Henry VIII., whilst several other varieties of arms having a movable breech-block were made prior to his reign. Small-arms and cannon with detachable breech-plugs—in which the charge was placed and fired—were made in the 16th century, and before its close breech-loaders with hinged barrels had been introduced. The hinge was usually at the joint, as in the weapon illustrated (fig. 7), and not a couple of inches forward of it, as in the Lefauchaux and other modern developments of the sporting gun. The 17th and 18th centuries were particularly prolific in the production of breech-loading mechanisms, but, owing to the absence of a cartridge containing its own ignition, none were successful until revived after the introduction of the percussion cap.

Amongst the early manufacturers of arms who aided the development by their handicraft or invention the Italian and Spanish smiths deserve mention; the accurately forged barrels of Nicolas Bis, and the fine workmanship on the pistols of the Comminazzo family, cannot be surpassed. Köllner of Vienna, and Kotter of Nuremberg, produced rifling; and Lazarino, Dax, and Nereiter improved the appearance and handiness, and added to the utility of firearms by minor inventions. The wheel-locks were neither manufactured nor used extensively out of Germany and Italy, but the Saxon collection in the Dresden Museum indicates the importance with which the invention was once regarded. The most curious arms were manufactured in Paris, Amsterdam, Hanover, Liège, and Lisbon, and later at the Moscow arsenal.

That necessity is the mother of invention has never been more truthfully demonstrated than by the development of firearms. The wars in Flanders and Germany during the middle ages quickened the genius of their inventors and improved the skill of their armourers; just as the tension in mid-Europe since the war of 1870-71 has given to France and Germany the finest repeating rifles and best artillery; whilst the leisure and taste of the Englishman has called for the finest sporting weapons. The invention of rifling in Germany in the 15th century led to the development of weapons of precision, the highest degree of accuracy being attained by a heavy muzzle-loading small-bore rifle with a high trajectory. The requirements of the military firearm—lightness, ease and quickness of manipulation, extreme range and great velocity, have led to the sacrifice of precision for the advantages possessed by light breech-loading arms (see BREECH-LOADING, and RIFLES).

Of the inventions which have been applicable to all firearms the most important has to do with the *ignition* of the charge of explosive. Fulminating or detonating powders were made by the French chemists of the 18th century; and about 1800 an Englishman, benefiting by their experiments, produced a highly sensitive explosive, composed of fulminate of mercury and saltpetre, which possessed all the requisite qualities of a priming powder for the flintlock firearms. In 1807 Alexander J. Forsyth, a Scottish clergyman, patented the application of the detonating principle for exploding gun-powder in firearms. Many inventors claimed the

copper percussion-cap which followed and was first made in England in 1818, its introduction leading to the abandonment of the firelock. The expansive bullet, invented by Greener and improved by Minié, increased the range and accuracy of rifles, and made an accurate breech-loading rifle possible. The cartridge-case containing its own means of ignition, or the percussion-cap, is a French invention improved by Lefauchaux, Lancaster, Needham, Pottet, and others, and to it is due the success of modern breech-loading small-arms, this cartridge-case of solid drawn brass being used for all quick-firing machine guns and some of the smaller cannon. The expansion of the case at the moment of discharge causes it to act as an obturator and block all escape of gas into the breech-loading mechanism, whilst its contraction after firing admits of its being withdrawn with ease.

Sporting firearms consist of the shot-gun and the rifle for large game shooting. The use of hail-shot became general in Germany in the 16th century, and with the introduction of the wheel-lock the use of the arquebus for sporting purposes became more common. The earliest double-barrelled guns were made for military purposes, but sporting guns with two barrels side by side were made in Italy in the 17th century, and the art of shooting on the wing was first practised about 1580. The introduction of better forged barrels in the latter half of the 18th century made a light double-barrelled fowling-piece a possibility, and since then shot-gun barrels made of iron and steel fragments (1798) and twisted scelps (1806) have increased in strength and lightness. Old horseshoe nails and scraps of iron and steel were made into shot-gun barrels; but after 1850 new metal was employed and is now preferred. As the fowling-piece with hand-welded barrels made of twisted rods became more general, the supremacy of continental gun-makers over the English was lessened, and early in the 19th century the improvements made by Manton, Nock, Cook, Egg, and others placed English guns ahead of all competitors. The French invention of composite cartridge-case and breech-loading was turned to practical account by the English, who have unceasingly improved upon the original idea. In addition to the breech-loading mechanism, the shot-gun has been improved in range by the use of choke-boring—i.e. the constriction of the barrel at the muzzle; in safety, by the rebounding lock, which again has been superseded by various hammerless locks, or arrangement of the firing mechanism within the head of the gun; and in self-ejecting mechanism. See BREECH-LOADING; also GUN (Sporting).

The sporting rifle is a type of firearm evolved from the wheel-lock hunting weapons of Germany. Its production is proof of the adaptability of firearms to special needs; the desiderata of a weapon for large game hunting include the quick firing of a second shot, and a paralysing effect from the penetration of the bullet. The repeating rifle cannot be twice fired as quickly as the double rifle, and length of range with a light ammunition and continuous quick firing are points sought in a military weapon. Precision is dependent upon the weight of the projectile being sufficient to maintain the direction imparted to it during its passage through the barrel. The bullet is helped to do this by the rifling giving the projectile a rotary motion, which equalises irregularities in the bullet, and lessens its tendency to deflect. The greater the velocity, the less quickly must the rifling turn; but with improved solid bullets, covered with nickel or steel, it is possible to get the bullet to grip the rifling at a velocity of 2000 feet per second, and a complete turn is made in ten inches, in which case the bullet has a double

rotary motion and takes a corkscrew flight. The modern sporting or express rifle, as it is termed, fires a hollow expansive bullet at a high velocity, extreme accuracy and long range being sacrificed for greater force at impact. Firearms are also used for signalling at sea, throwing lines, harpooning whales, and other special purposes.

Modern weapons are conditioned chiefly by the purpose for which they are designed, and further development in any direction is stayed sometimes by one consideration, as increased weight, and in others by the limit of size, cost, or inability to combine with an improvement some essential requirement. Size is usually designated by the calibre, which is the diameter of the bore of the firearm before it is grooved. To obtain the highest results from the full load the length of the barrel must be proportionate to its calibre, and this is usually standardised at 50 calibres. Any hand-firearm must be 100 times the weight of its projectile if recoil detrimental to good shooting is to be avoided; but with cannon a part can be transferred to the gun-mountings. With big cannon the size is not so often limited by their unyieldiness as by the strength of the material, for the strain at the breech end on firing them causes local expansion, which results in a permanently bent weapon. The weight of a projectile is proportionate to the calibre; roughly, the cube of the diameter in inches when halved gives the weight in pounds. With rifled small arms, of calibre suitable for the range, it is possible to hit the smallest object visible at any distance, the mean deviation of the bullet being about half the angle at which ordinary eyesight subtends. Standard targets for all distances between 15 feet and 1500 yards are calculated on this basis. Prismatic telescope-sights of low magnifying-power aid vision and render accurate shooting at long distances possible, but military rifles are sighted for shooting up to about 3000 yards. The limit of accurate shooting is ordinarily about a third of the extreme range. Rapidity of fire with machine, repeating, and automatic guns is scarcely limited by the time required for the mechanism to function, but by the heating of the barrel. The multi-barrelled Gatling, a mitrailleuse, has been fired over 1300 times a minute, but the single-barrelled machine-guns when shot at a speed of 500 rounds a minute heat so rapidly that the accuracy of the shooting is impaired, the inner surface of the barrel eroded, and gas escaping into the mechanism causes a jam. In 1912 the Ross-Eley 280-calibre high-power rifle shot a bullet of 143 grains with a muzzle velocity of 2950 feet per second. A heavier bullet would result in higher pressure, more recoil, and a lower velocity. To get more power the calibre may be increased, but a heavier weapon is then needed. More explosive means a longer cartridge-case or one of greater diameter at the base. With the former, extraction of the fired case would be difficult; with the latter, extra strain in excess of the present proportion would be transferred from the walls of the cartridge-chamber (barrel) to the breech-bolt, which, together with the whole breech-mechanism, would have to be strengthened and remodelled. In 1915 an explosive was introduced with which in this rifle a muzzle velocity of 3300 feet per second was obtained, and a higher-power weapon resulted. For the capabilities of various weapons, see CANNON, RIFLES, REVOLVERS, &c.

The firearms industry in London dates from 1545, in Birmingham from 1683, but cannon were made there at earlier dates, and at Perugia 500 hand-cannon were made in 1364. Centres of the industry in Europe are Liège, Birmingham, St Etienne, Suhl, Steyr, Brescia, Eibar, and Tula. Sporting weapons are still largely made by hand,

military small-arms by machinery on the interchangeable plan originated by Whitney in 1797, followed by Hall in 1818, and in England since 1856. Certain parts are not now made interchangeable, as the breech-bolts of rifles which are 'seated' by pressure.

For the early history of firearms, see *Quellen zur Geschichte des Feuerwaffen* (Leipzig, 1872); Grose's *Military Antiquities*, Wilkinson, *Engines of War* (1841); Greener, *The Gun and its Development* (1910). For modern arms, J. H. Walsh ('Stonehenge'), *Modern Sportsman's Gun and Rifle* (1882-84), and *Weapons of War* (1885). For firearms manufacture, Brandeis, *Moderne Gewehr-Fabrikation*; and Greener, *The Gun*.

PROVING OF FIREARMS, in Law. All weapons manufactured or offered for sale in England must be proved either at one of the government proof-houses in England or at the Banc d'Epreuve at Liège. A royal charter granted in 1637 to the London gunmakers gave them powers to search for and prove and mark all manner of hand-guns, great and small daggs, and pistols. The several statutes of 1813, 1819, and 1855 rendering the proving of firearms compulsory have been superseded by the Gun-barrel Proof Act, 1868 (31 and 32 Vict.), regulating the duties and powers of the proof-houses in London and Birmingham (the only two in England). By this statute the forging or counterfeiting of the proof-marks or stamps is treated as a misdemeanour punishable by imprisonment for not more than two years; and a fine of £20 is imposed on any person selling or exposing for sale barrels not duly proved, or exporting or importing barrels with forged proof-marks. These penalties are to be levied on conviction before two justices or a metropolitan or stipendiary magistrate. The statute does not extend to Scotland or to Ireland, and arms manufactured for His Majesty are exempted from its operation.

The introduction of new and more powerful explosives and guns of improved types has necessitated changes in the proof-house tests. The most important provides that weapons shall be tested with such explosives and projectiles as those with which they will be charged in actual use. Orders in Council regulate the tests to be applied, and these change as new explosives are introduced.

Fireball is the popular name of projectiles, other than rockets, used for incendiary or illuminating purposes. They are more properly called *carcasses*, or *ground* and *parachute light-balls*. The carcass was a thick shell filled with fiercely burning composition, and having large holes, or vents, out of which it streamed. The ground light ball was filled with brightly burning composition, and burned on the ground. The parachute shell was fired from a mortar, and fuzed so as to open in the air and support, by means of a parachute packed inside it, a pan of brightly burning composition. The electric light has superseded these last two, and the rocket the first.—For other kinds of fireball, see LIGHTNING, METEORS.

Firebote, the right of a tenant, according to English law, to cut wood on the estate for the purpose of fuel. See ESTOVER.

Fire-brigade. See FIRE.

Fireclay is the variety of clay which is used for the manufacture of firebricks, gas-retorts, crucibles, glass pots, chimney-pipes, and other articles, most of which require to resist the action of high and long-continued heat. Ordinary fireclay is chiefly found in beds not usually much exceeding two feet in thickness, in the coal-measures, interstratified with seams of coal and other rocks. In the British Islands it is most largely worked about Glasgow, Newcastle-on-Tyne, and Stourbridge in Worcestershire, at which last

place it is said to have been discovered about 1555 by some wandering glassmakers from Lorraine. But it occurs, more or less, in most places where true coal is found. It is mined in Germany, Belgium, France, the United States, and other countries. Stourbridge fireclay, owing to its excellent quality, is largely exported to foreign countries, as well as bricks and other objects made of it. Refractory clays are found, though more rarely, in other formations besides the coal-measures. For example, some of Tertiary age found in Dorsetshire and Devonshire are made into firebricks. The following table shows the principal constituents of fireclay:

	No 1	No 2	No 3	No 4	No 5
Silica	65.10	51.10	59.49	53.52	54.20
Alumina	22.22	31.35	28.95	33.68	33.80
Potash18			trace	trace
Lime14	1.46	trace	.76	trace
Magnesia15	1.54		.14	.02
Oxide of Iron	1.92	4.63	1.05	.52	.01
Water	9.28		11.05	11.34	10.86
Organic Matter58	10.47			15

No. 1, Stourbridge; No. 2, Newcastle-on-Tyne; No. 3, Gartsherrie, Scotland; No. 4, Poole, Dorsetshire; No. 5, Morgantown, West Virginia, United States. See CLAY.

Fireclays from the same locality often differ considerably in their composition and quality. Some of the Newcastle clays, for example, contain from 70 to 80 per cent. of silica with from 9 to 18 per cent. of alumina. A high percentage of silica and alumina together (their relative proportions being comparatively immaterial) and small quantities of alkaline substances and oxide of iron constitute a refractory fireclay. If not small in amount, alkaline bodies in the clay tend to make it easily fusible, so that bricks formed of it are apt to soften and yield in a furnace. Fireclays are generally yellow in colour after being fired in the kiln. No very sharp line of distinction can be drawn between hard infusible clays and softer marly clays used for terra-cotta, garden vases, and some kinds of house bricks. In districts where fireclay is abundant composition bricks for ordinary building purposes are partly made of it. For furnace-building materials which resist the action of a very intense heat, such as dinas and bauxite bricks, see BRICK-MAKING. Powdered flint, as well as chrome iron ore, is likewise used for furnace bricks.

Firedamp. is the miners' term applied to light carburetted hydrogen or coal-gas when it issues from crevices in coal-mines (see GAS). These crevices are named 'blowers' by the miners, and are evidently the outlets of gas that exists in a compressed state in pores and cavities in the coal. The issue of the gas is in some cases audible, and on applying a light it burns as a jet of flame. When mixed with air in proportions between $\frac{1}{4}$ to $\frac{1}{3}$ of its volume the mixture is explosive, producing disasters that are too well known. The researches of Galloway and others have shown that the gas is only one of the factors producing the worst catastrophes. A comparatively small explosion of gas stirs up any coal-dust that may be lying on ledges, or on the floor of roads and workings, each particle of dust is fired, and the combined result is like the firing of grains of gunpowder.

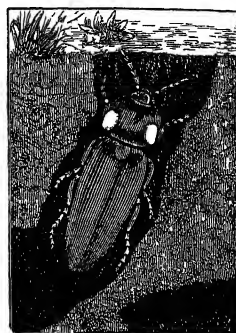

Fire-engine, Fire-escape. See FIRE.

Firefly, a name applied to many 'phosphorescent' insects, which are all included within the order Coleoptera, or beetles. Some of them (among the Elaterids) give forth a steady light, and these may be distinguished as fireflies proper from the Glow-worms (q.v.) and 'lightning-bugs' (among the Lampyrids), which flash light intermittently. In the phosphorescent Elaterids, furthermore, the production of light has its seat more anteriorly

than in the Lampyridæ, where it is abdominal. As the Lampyrids will be discussed under GLOW-WORM, only the Elaterid fireflies need be noticed here.

The most brilliant fireflies are species of *Pyrophorus*, most at home in tropical America. One form—*Pyrophorus noctilucus*—common in the West Indies and Brazil, attains a length of about an inch and a half, and has a dark rusty-brown colour.

On the upper surface of the first ring of the thorax are two yellowish oval spots, which are brilliantly luminous during the nocturnal activity of the beetle, while on the first ring of the abdomen a still brighter organ is situated. Even the eggs are luminous, and excised portions placed in a damp chamber remain functional for two or three days. The pounded debris of the insect is also luminous.

Common Firefly (*Pyrophorus noctilucus*) in burrow of mole-cricket, showing the two oval phosphorescent organs on the thorax.

The luminous organs are special modifications of the epidermic (*hypodermis*) cells, which are disposed in two layers, of which the outer alone is luminous, while the inner contains masses of waste products, and is riddled by air-tubes. The luminosity depends on a process of oxidation by a zymase (*luciferase*) in the blood, and the brilliancy varies with the respiratory activity, being apparently only indirectly affected by the nervous system. What the substance oxidised (a protein which Dubois called *luciferin*) really is remains undiscovered. On the sleeping or entirely passive insect a soft light may be observed; the real blaze is only exhibited during active respiration, and may be exaggerated experimentally by blowing in oxygen or supplying an oxidising agent. The function of the light is not understood. It does not seem (as in the Lampyrids) to be sexual.

The light of these living lamps, or *cucujos*, as the Mexicans call them, has frequently saved a traveller's life; the Indians 'travel in the night with fireflies fastened to their hands and feet, and spin, weave, paint, and dance by their light,' and they are often used for decorative purposes. A few of them in a glass vessel give light enough to read by, and when not wanted for any such purpose they may be set to catch mosquitoes in the house. In Vera Cruz, according to C. F. Holder, the *Pyrophori* are so commonly used as toilet ornaments that they form an important article of trade. The natives lure them by means of lights waved on the end of sticks, and catch them in nets. They are then placed in a box covered with a wire netting, bathed twice a day in tepid water, and at night fed with sugar-cane.

See GLOW-WORM, PHOSPHORESCENCE; C. F. Holder, *Living Lights* (Lond. 1887); R. Dubois, *Les Elatérides lumineux* (Meulan, 1886); F. F. Moore, *Fireflies and Mosquitoes* (Lond. 1888); K. G. Blair in *Nature*, Dec. 1915; papers quoted by Holder. For a detailed account of the anatomy and physiology of *Pyrophori*, see C. Heine-mann, *Archiv. f. mikr. Anat.* XXVII. (1886), pp. 296-382.

Fire-insurance. See INSURANCE.

Firelock. See FIREARMS.

Firenzuola, AGNOLO, Italian writer, was born at Florence, 28th September 1493. Having studied law at Siena and Perugia, he began to practise as an advocate in Rome. But in a few years he enrolled himself in the monastic order of Vallombrosa.

On the death of Clement VII. he left Rome, and finally became abbot of Prato, where, or at Rome, he died before 1548. His chief works are a spirited paraphrase of the *Golden Ass* of Apuleius, a work in close imitation of the *Decameron*, a eulogistic discussion concerning the charms of the fair sex, a couple of comedies, and some poems. Firenzuola's works are distinguished for the classic elegance of their style, as well as notorious for their licentiousness. The best collected edition is one published at Florence (2 vols. 1848).

Fire-raising, in the law of Scotland, is the equivalent term for Arson (q.v.) in England.

Fire-ship, a vessel, usually an old one, filled with combustibles, sent in among a hostile squadron, and there fired, in the hope of destroying some of the ships, or at least of producing great confusion. Livy mentions the use of such by the Rhodians, 190 B.C. Earliest in modern times, so far as known, they were employed by the Dutch in the Scheldt during the war of independence in the Netherlands, and shortly after by the English, in 1588, against the Spanish Armada. Lord Dundonald (q.v.) employed them against the French in 1809; and the Chinese tried them against the British fleet in 1857. Ships with ballast and combustibles were repeatedly used by the Japanese at Port Arthur in 1904, but rather to block the channel of the harbour when exploded than to damage the Russian ships.

Fireworks. See PYROTECHNY.

Firishta. See FERISHTAH.

Firkin (dim. from *four*), an old measure of capacity containing 9 gallons (old ale and beer measure). But previous to the year 1803 it had two values, being estimated at 8 gallons in old ale measure, and at 9 in old beer measure. The firkin is equivalent to 9½ imperial gallons. The name is also applied to a small wooden cask, as for butter. This contains 56 lb.

Firlot (from *four*), an old Scottish dry measure, of which there were four in a Boll (q.v.). Though differing in value for different substances and places, its relation to the boll remained invariable. See PECK.

Firm. See PARTNERSHIP.

Firmament, a word formerly used to signify the vault of heaven. The term found its way into English from the Vulgate, which renders the Septuagint *stereōma*, and the Hebrew *rakia*, by the Latin *firmamentum* (Gen. i. 6). *Rakia* (from the verb *raka*, 'to beat or strike out') signifies whatever is expanded or stretched out, and was specially employed by the Hebrews to denote the hemisphere above the earth, compared (Exod. xxiv. 10) to a splendid and pellucid sapphire. Elsewhere (Ezek. i. 22-26) it is spoken of figuratively as that on which the throne of the Most High is placed. Hence it follows that the notions of solidity and expansion were both contained in the Hebrew conception of the firmament. The blue ethereal sky was regarded as a solid crystal sphere, to which the stars were fixed (compare the *caelo affixa sidera* of Pliny, ii. 39 and xviii. 57), and which was constantly revolving, carrying them with it. This sphere or firmament divided 'the waters which were under the firmament from the waters which were above the firmament'; and the theory of the phenomena of rain, &c. was that there were 'windows in heaven'—i.e. in the firmament, through which, when opened, the waters that were above the firmament descended. 'The same day were all the fountains of the great deep broken up, and the windows of heaven were opened' (Gen. vii. 11). The view entertained by the Greeks and other early nations was essentially the same. In the

progress of astronomical observations it was found that many of the heavenly bodies had independent motions, inconsistent with the notion of their being fixed to one sphere or firmament. Then the number of crystalline spheres was indefinitely increased, each body that was clearly independent of the rest having one assigned to it, till a complex system was introduced, capable of being fully understood only by the philosophers who formed it (see PTOLEMAIC SYSTEM). It was long before men conceived the idea of the possibility of a body being maintained in motion in space without a fixed support, and, considering the number of phenomena of which the hypothesis of a crystalline firmament offered an apparent explanation, we must regard it as having been in its day a curious and ingenious speculation.

Firman, a word of Persian origin, signifying an order, and used by the Turks to denote any official decree emanating from the Ottoman Porte. The right of signing any firman relating to affairs connected with his special department was exercised by every minister and member of the divan, but the office of placing at the head of the firman the *tughra*—a cipher, or monogram, containing the names of the sultan and of his father in interlaced letters, which alone gave effect to the decree—was committed to the hands of a special minister, called *nishānī-bashi* (see S. Lane-Poole, *Turkey*, in the 'Story of the Nations' series). The name applied to such decrees as had been signed by the sultan himself is *hatti-sherif* (properly *Khatt-i-sherif*). The name firman may also signify a more formal kind of Turkish passport, which was granted by the sultan or by a pasha.

A written permission to trade is called in India a firman.

Firminy, a town in the French department of Loire, 9 miles SW. of St Étienne by rail. Near it are rich coal-mines; and railway material, big guns, and other iron goods are manufactured in large quantities. Pop. 20,000.

Firn (Ger., 'last year's'), snow in process of consolidation into glacier-ice; in French *névé* (Lat. *nix*, *nivem*, 'snow').

Firozabad, a town of India, United Provinces, 24 miles E. of Agra, with numerous ruined buildings; pop. 13,500, about two-thirds Hindus.

Firozpur, or FEROEZPORE, a town in the Punjab, 3½ miles from the left or south-east bank of the Sutlej. Founded, it is said, by Firoz Shah (1351-87), and at one time a large and important town, it had sunk into poverty and insignificance before it actually came, in 1835, into the possession of the English. Since then the place has regained much of its former consequence, and it possesses the largest arsenal in the Punjab. It contains a church built in memory of those who fell in the Sikh wars (1845-46). Pop. 50,000, of whom about half are in the cantonment 2 miles south.—Firozpur district has an area of 4300 sq. m., and a pop. of a million. Much has been done, since British occupation, to increase the value of this once dreary and desert plain, by tree-planting and otherwise, and now most of the district is under cultivation.

Firozshah, a battlefield in the district of Firozpur, 12 miles from the left bank of the Sutlej, the scene of the attack of the British forces, led by Sir Hugh Gough and Sir Henry Hardinge, on the Sikh camp, 21st December 1845. The entrenchments were carried and the natives routed after two days' fighting.

First Aid. See AMBULANCE, BANDAGE.

First-born (Heb. *bekor*, Gr. *prototokos*, Lat. *primogenitus*), in scriptural use, signifies the first

male offspring, whether of man or of other animals, due to the Creator by the Mosaic law as a recognition of his supreme dominion. The first-born male, whether of men or of animals, was devoted from the time of birth to God, and the first-born male child had to be redeemed one month after birth by an offering not exceeding in value five shekels of silver (Exod. xiii. 13), provided the child lived longer than that period. The first-born male of animals also, whether clean or unclean, was equally regarded as devoted to God; that of clean animals, if free from blemish, was to be delivered to the priests within twelve months after birth, to be sacrificed to the Lord; nor was it permitted to any but the priests to partake of the flesh of such victims. If the animal were blemished, it was not to be sacrificed, but to be eaten at home. The first-born of unclean animals, again, was either to be put to death or to be redeemed with the addition of one-fifth of its value; if not redeemed, to be sold, and the price given to the priests. By the Mosaic law primogeniture had certain privileges attached to it, the chief of which were the headship of the family and a double portion of the inheritance. Among other nations considerable variety existed as to the succession of children to the inheritance of their parent, for the discussion of which see the articles ENTAIL, FAMILY, FEUDALISM, LAND-LAWS, and SUCCESSION.

First-fruits (Heb. *reshith*; Gr. *protogennēmata*, and *aparchai*; Lat. *primitiæ*), that portion of the fruits of the earth and other natural produce which, by the usage of the Jews and other ancient nations, was offered to God as an acknowledgment of his supreme dominion, and as a thanksgiving for his bounty. Among the Jews the institution of first-fruits comprised both public and private offerings. Of the former the three principal were made at the opening of the corn-harvest, at the Feast of Pentecost, and at the Feast of Tabernacles. The private offerings made by individual Jews were a cake of the first dough of the year and the 'first of all the fruits.' All these offerings were divided into two classes: *Bicurim*, comprising the various kinds of raw produce, of which, although the law seems to contemplate all fruits, seven sorts only were considered by the Jewish doctors to fall under the obligation of first-fruit offering—viz. wheat, barley, grapes, figs, pomegranates, olives, and dates; and *Terumoth*, or the produce of the year in the various forms in which it is prepared for human use, as wine, wool, bread, oil, date-honey, dried onions, and cucumbers.

Offerings analogous to the Jewish first-fruits became usual very early in the Christian church, as is clear from a passage in Irenæus, but appear to have been merged in the legal provision established by the emperors. The medieval ecclesiastical impost known under the name of *primitiæ* or first-fruits, and sometimes of *annates* or *annalia*, was entirely different. See ANNATES.

First of June. See HOWE (RICHARD).

Firth, or FRITH, an estuary, from the same root as *ferry*; Dan. *fjord*; akin to Lat. *portus*, and Gr. *porthmos*. For the firds, see NORWAY.

Firth, MARK (1819-80), born in Sheffield, in 1849 with his father and brother established there the great Norfolk steel-works, whose specialty soon became the manufacture of steel ordnance. He was a munificent benefactor to his native town, his gifts including almshouses (1869), a public park (1875), and the Firth College (see SHEFFIELD).

Fisc (Lat. *fiscus*, 'a wicker-basket'), an old term for a prince's treasury. The word 'fiscal' is a derivative; as also Procurator-fiscal (q.v.).

Fiscal Question. See FREE-TRADE, PROTECTION.

Fischart, JOHANN, one of the most original German satirists, known also under the name of Huldreich Elliposkleros, was born either at Mainz or Strasburg, about the middle of the 16th century. He was brought up at Worms, studied law at Strasburg, became in 1581 advocate to the Imperial Chamber at Spire, and in 1585 bailiff of Forbach near Saarbrücken, where he died in 1590 or early in 1591. Of the very numerous writings, which appeared from 1570 to 1590, partly under his own and partly under fictitious names, about fifty have been proved to be on the whole genuine, though disfigured by interpolations. In respect to others, however, the authorship is doubtful. His most celebrated works are based on foreign models, particularly Rabelais, but manifest no servile imitation: a free creative genius everywhere works plastically on the materials. To this class belong his *Aller Practick Grossmutter* (1572); *Affentheurliche Geschichtschrift vom Leben der Helden Grandgusier, Gargantua und Pantagruel* (1575); *Podagrammisch Trostbuchlein* (1577); and *Bienenkorb des Heyligen Romischen Imenschuarms* (1579). These writings are wholly satirical. With the most inexhaustible humour he lashes, now the corruptions of the clergy, now the astrological fancies, the dull pedantry, or other follies, public and private, of the time. Next to these stands the outrageously comic work of Fischart's—quite original in its conception—entitled *Flohkatz, Weibertratz* (1573). Essentially different in its homely and simple tone is *Das glückhafte Schiff von Zurich*, written in verse, and published in 1576. Similar in point of style are his *Psalmen und Geistliche Lieder* (1576). The rest of Fischart's numerous writings, partly in prose, partly in verse, are of unequal merit, singularly varied in style and contents; but throughout all we find the same rich satirical humour, the same warm and genuine feeling for the moral foundations of all public and private life—religion, fatherland, and the family. His works are, moreover, one of the richest sources for the manners of his time. In his treatment of the language no German author can be compared with Fischart, not even Jean Paul Richter himself. He coins new words and turns of expression without any regard to analogy, but nevertheless displays the greatest fancy, wit, and erudition in his most arbitrary formations.

See Vilmar, *Zur Litteratur J. Fischarts* (2d ed. 1865); Von Meusebach's *Fischart-studien* (edited by Wendeler, 1879); and Ganghofer, *Johann Fischart und seine Verdeutschung des Rabelais* (1881).

Fischer, EMIL, organic chemist, was born at Euskirchen, Rheinland, 9th October 1852. He studied at Bonn and Strassburg, assisted Von Baeyer at Munich for eight years, and was professor at Erlangen (1882), Würzburg (1885), and Berlin (1892), where he raised the chemistry school to the highest repute, and where he died, 15th July 1919. He undertook successfully the solving of problems of extreme difficulty and complexity in organic chemistry. He studied especially the rosanilin dyestuffs, uric acid and allied substances, with their base purin (which he obtained), and especially the carbohydrates and ferments, and the proteins. He succeeded in preparing many organic substances synthetically. He was awarded a Nobel prize in 1902.

Fischer, ERNST KUNO BERTHOLD, the son of a country pastor, was born in the Silesian village of Sandewalde, 23d July 1824. From the Posen gymnasium he passed to the university of Leipzig, where he attended lectures on philology and theology; but after his first session he went to Halle, and here, under the influence of Erdmann and Schaller, becoming interested in philosophy,

he resolved to devote himself to this as his life-study. He took his Ph.D. degree in 1847, and in 1850 established himself at Heidelberg as a *privatdozent* of philosophy. His eloquence and his poetical sympathies, in addition to his actual knowledge of philosophy, now stood him in good stead. Students came in flocks to hear him, and his enormous popularity, resulting from his enthusiasm, deep insight, and clearness of exposition, increased steadily. Suddenly, however, in July 1853, presumably because of private charges of pantheism made against the first volume of his *History of Modern Philosophy*, the Baden government without any explanation deprived him of his position as *privatdozent*. During three years of academic exile that followed, Fischer lived quietly with kindred spirits amid the beautiful surroundings of Heidelberg, and continued meantime to work at his *History*, publishing between 1853 and 1856 the volumes on Spinoza, Leibnitz, and Bacon. In 1856 he received a call to Fichtes old chair of philosophy at Jena; and in Jena he laboured for sixteen years. At last, in 1872, when Eduard Zeller succeeded Trendelenburg at Berlin, Fischer—all practical difficulties in connection with the freedom of lecturing having now disappeared—obtained Zeller's post at Heidelberg. He resigned in 1906, and died 4th July 1907.

Fischer's chief work is his great history of modern philosophy, *Geschichte der Neuern Philosophie* (1852-93). His historical books seek to do for modern philosophy what Zellers do for old-world systems. His other great philosophical achievement is his *System der Logik und Metaphysik* (1852; new ed. 1865), in which, while he adheres in the main to Hegel's position, he yet criticises Hegel severely on many important points. Of his other philosophical writings the most noteworthy is a *Critique of Kant*, which, like Bacon and Descartes and his *School*, has been translated into English. Other works deal with Goethe (1878-1904), Lessing, Schiller, Shakespeare's *Hamlet* (1896), and the history of Heidelberg. See a monograph by Falkenheim (1892).

Fish, HAMILTON, American diplomatist, was born in New York city in 1808, graduated at Columbia, and was admitted to the bar there in 1830. A Whig in politics, he was elected a congressman in 1842, lieutenant-governor of the state in 1847, and governor in 1848. In 1851 he was returned to the United States senate, where he acted with the Republican party. He was secretary of state under Grant from 1869 to 1877, signing, as one of the commissioners, the Washington Treaty of 1871, and carrying through the settlement of the Alabama Question (q.v.). He retired in 1877, and died 7th September 1893.

Fish. See FISHES, ANGLING, FISHERIES, PISCICULTURE.

Fisher, a kind of Marten. See PEKAN.

Fisher, ANDREW, Australian statesman, was born at Crosshouse, near Kilmarnock, 29th August 1862. After working as a miner, he went to Queensland in 1885, sat in the Colonial and Commonwealth parliaments, was Commonwealth minister for trade and customs (1904), and leader of the Federal Parliamentary Labour Party (1907). He was prime-minister in 1910-13, 1914-15, but resigned to become High Commissioner for Australia in London (1916-21).

Fisher, HERBERT ALBERT LAURENS, historian and statesman, born in London, 21st March 1865, was educated at Winchester, Oxford, Paris, and Göttingen. He delivered lectures, served on royal commissions, contributed to the *Cambridge Modern History*, wrote a life of F. W. Maitland, books

on Napoleon and other subjects of European and English history, and in 1912-16 was vice-chancellor of Sheffield University. From 1916 he sat as a (Coalition or National) Liberal for Sheffield (Hallam) and for the combined English universities. He was president of the Board of Education in 1916-22. For his Act of 1918, see EDUCATION.

Fisher, JAMES. See UNITED PRESBYTERIAN CHURCH.

Fisher, JOHN, Bishop of Rochester, was born about 1469 at Beverley, Yorkshire, and in 1483 entered Michael-house, Cambridge, of which he became a fellow in 1491, and master in 1497. In 1502 Margaret, Countess of Richmond (1443-1509), Henry VII.'s mother, was led by his virtues and learning to make him her chaplain and confessor; and in 1503 he was appointed first Lady Margaret professor of Divinity. Next year he was elected chancellor of the university, and consecrated to the see of Rochester. Thirty years he laboured diligently for the welfare of his diocese and university. A friend of More and Erasmus, a man who at forty-six began Greek, at fifty Hebrew, he zealously promoted the New Learning, and advocated reformation from within; as zealously both by voice and by pen he resisted the Lutheran schism. So early as June 1527 he pronounced firmly against the divorce of Henry VIII.; and having lent too ready an ear to the 'revelations' of the Holy Maid of Kent, Elizabeth Barton (q.v.), in March 1534 he was attainted of misprision of treason, and next month, for refusing the oath of succession, was sent with More to the Tower. In May 1535 the new pope, Paul III., made him a cardinal; Cromwell told it to Henry. 'Yea,' said the king, 'is he yet so lusty? Well, let the pope send him a hat, but I will so provide that he shall wear it on his shoulders, for head he shall have none to set it on.' He kept his word. On 17th June the old man, worn by sickness and ill-usage, was tried for denial of the king's supremacy; on the 22d, still cheerful and courageous, he was beheaded on Tower Hill. His head was fixed on London Bridge; his body was ultimately buried in the chapel of St Peter in the Tower. In 1886 he was beatified. See Life by Bridgett (1888).

Fisher of KILVERSTONE, BARON (SIR JOHN ARBUTHNOT FISHER), G.C.B., O.M., admiral and naval administrator, was born 25th January 1841. Entering the navy in 1854, he served in the Crimean war, in the China war of 1859-60, and in Egypt in 1882. He was Director of Naval Ordnance 1886-91; Admiral Superintendent at Portsmouth 1891; Controller of the Navy; a Lord of Admiralty 1892-97; Commander-in-chief on the North American and West Indian Station 1897-99, on the Mediterranean Station 1899-1902; Second Sea Lord 1902-3; Commander-in-chief, Portsmouth, 1903-4; First Sea Lord 1904-10; Admiral of the Fleet 1905. He carried out—not without fierce opposition—many revolutionary changes in naval organisation, such as the Dreadnought policy, ruthless scrapping of old ships, and sacrifice of tradition for efficiency in dealing with personnel or other matters. He returned to the Admiralty as First Lord on the outbreak of the Great War, but disagreed with Mr Churchill over the Dardanelles expedition, and resigned in 1915, but continued to give help to the Admiralty as Chairman of the Inventions Board. He wrote *Memories* and *Records* in 1919, and died 10th July 1920. His often-repeated cry of 'Sack the lot' expresses his method and personality and exemplifies his literary style, but gives a very inadequate notion of his achievement. See NAVY.

Fisheries include all operations for the taking of aquatic animals, not only fishes proper, but shellfish (molluscs and crustaceans), whales, seals.

turtles, trepang, sponges, coral, and whatever else man finds a use for. They have been, and are, an important source of food and other things of value from Palæolithic times, and in all parts of the world where fish are found; and a vast variety of methods could be enumerated. Besides trawls, drift-nets, seines, and other nets described below (see also NETS), hooks and gorges (see ANGLING, FISH-HOOKS), and traps such as the lobster-pot, fish can be taken (not everywhere legally) by hand (tickling, gumping, guddling); by tame cormorants, as in China; by poison, explosives, arrows, tridents, including the leister, with which salmon used to be caught, and spears. The whaler's harpoon is but a development of the barbed spear of primitive man. For fishing as a sport, see ANGLING. For the law, see POACHING, SALMON. For the cultivation of fish, see PISCICULTURE.

Nearly all the most important marine fish on the coasts of Europe and North America are valuable as food, some being held in great estimation as delicacies by the rich, others forming a staple food of the poor. The chief exceptions are the dog-fishes, which are extremely abundant and at the same time of no value as food, although they are occasionally eaten in some places on the coast. The other most valuable marine animals on the European coasts are the lobster, crab, crayfish, shrimps, and prawns among Crustacea, and certain molluscs, chiefly the oyster, though mussels, clams or scallops, and whelks are of some value. Except in extensive fresh-water lakes, true fresh-water fishes are of minor importance, but there are several valuable 'anadromous' fish which ascend rivers to a greater or less distance. The most important of these are the salmon and sea-trout, but the smelt and shad are abundant in some estuaries of Europe, and another species of shad (*Clupea sapidissima*) is abundant and highly valued in America. Eels also are largely eaten in Europe, and the sturgeon, though rare in Britain, is abundant in some large rivers of the Continent.

The geographical position of the British Islands, and the wide maritime influence which, as a people, we enjoy, have brought about great opportunities of fishing. Our sea fisheries are not by any means confined to the immediate neighbourhood of our coasts. For many years the greater part has been carried on in waters equally open to the fishermen of other nationalities, and not a little fishing has taken place off the coasts of other countries. The fish captured by men sailing from our shores are of unsurpassed quality; and the competition in the fishing, keen as it is amongst the various classes of fishermen, is shared by men of half-a-dozen other European countries. The actual numbers of fish landed slightly declined, in spite of the fact that the catching-power of the country was greatly increased. Since, however, there was an increase in value, this told the less upon the fishermen; but serious depression followed the Great War.

The great increase in the catching-power has come since the introduction of steam in fishing operations. With the increase in size and general efficiency in the vessels employed, also, more distant grounds can be explored, and have been explored, because the home waters have become almost insufficient to maintain the large fishing fleets. In this way the Dogger and Great Fisher Banks of the North Sea have become relatively less important. The German, Danish, and Norwegian coasts have been regularly visited, and Iceland has become an established locality. In a southern direction, also, trawlers have tried the deep waters of the Bay of Biscay, and the coasts of Spain, Portugal, and Morocco.

Maritime wars introduced much diversity of claim respecting neutral waters and territorial limitations. To go no farther back than the

American war of 1775, it may be stated that a train of sea-fights with France, Holland, and Spain followed. Treaties and decrees with respect to territorial limits followed the sea-fights, and the general result arrived at was that a cannon-shot determined the range of a country's influence from her coast. This interpretation was finally adopted by the great powers in international treaties, although Spain established in 1784 a ten-league limit, which is equivalent to a distance of about thirty-four English miles, in a fishery treaty between Great Britain and Spain concerning fishing in certain waters of the Pacific. This was in order to prevent illegal trading with the Spanish settlers at Vancouver. Similarly, in the North Sea a limit of one sea league, which was applied for purposes of neutrality, came to be applied early in last century for fishery purposes by Norway and Denmark, without reference to the distance of cannon-fire. The league of these Scandinavian countries, moreover, is reckoned as the fifth of a degree, or four miles, and is measured not from low-water mark, but from a line drawn across from the outermost points of outlying islands, an extensive sea area being thus frequently included.

Territorial limits for fishery purposes were for some years in a very unsatisfactory state, and no very safe guide could be obtained for the prevention of injury to the fishing-gear of vessels working in the North Sea. At the instance of the British Government, however, a definite inquiry was set on foot to ascertain the actual conditions which had to be met, and a conference was assembled at The Hague in 1881 to deal with this question from the international standpoint. As a result, the North Sea Convention of 1882 now fixes the limits for the signatories of the convention—viz Great Britain, Germany, France, Belgium, Denmark, and the Netherlands. The article as finally agreed upon reads as follows: 'The fishermen of each country shall enjoy the exclusive right of fishery within the distance of three miles from low water mark along the whole extent of the coasts of their respective countries, as well as of the dependent islands and banks. As regards bays, the distance of three miles shall be measured from a straight line drawn across the bay, in the part nearest the entrance, at the first point where the width does not exceed ten miles. The present article does not in any way prejudice the freedom of navigation and anchorage in territorial waters accorded to fishing-boats, provided they conform to the special police regulations enacted by the powers to whom the shore belongs.'

Denmark still clings to her measurement of one league so far as her Baltic coast is concerned, but in the matter of Iceland and the Faeroes she agreed to the three-mile limit. The only country which did not join in the convention, although the representatives were present at the final deliberations, was the then united kingdom of Norway and Sweden.

Some mention has also to be made of foreign trawlers. With the establishment of the three mile limit, and the prohibition, applicable only to British vessels, against trawling in the Moray Firth, the curious anomaly arose that, while foreign trawlers could not fish within three miles of the coast, they could fish, or apparently could fish, outside the three-mile limit, but inside the limits forbidden to British vessels. The Moray Firth in this way became almost a sort of preserve for German trawlers, to the great indignation of our own men. To mitigate in some measure the evils an act was passed, called the Trawling in Prohibited Areas Prevention Act, 1909. The object was to exclude foreign trawlers from working in waters *extra fauces* of Scotland, and its application extended to the whole of the United Kingdom. The provisions

of the Herring Fishery (Scotland) Act, 1889, which rendered illegal the landing or sale in Scotland of any fish taken by trawlers in prohibited areas, were incorporated. It had become evident that, to secure a benefit from the anomalous conditions indicated, a considerable number of English trawlers were registered under the Norwegian flag, and, with one or two Norwegian members of the crew to keep up the fiction, were boldly fishing where more straightforward Britishers were prohibited. The act, therefore, struck at these pseudo-Scandinavian trawlers, and in this particular it answered its purpose fairly well; but the general benefit was diminished by an almost corresponding increase of *bona fide* foreign trawlers who did not require to land their fish in any British port.

Trawling.—It was about the year 1878 that steam first came into use for propelling fishing-vessels, and the developments which followed from this were rapid. Trawling had up till then been practised by sailing-vessels, many of them able boats rigged as ketches, and being of 30 to 40 tons burden. Not only was the vessel propelled by steam, but the trawling gear was raised by steam. The net was the beam trawl, which was dragged along the bottom of the sea. This net was shaped as a long tapering pocket, the meshes being smaller at the tapering end than elsewhere. The tapering end, or 'cod end,' was not closed, but, before the operation of fishing began, was firmly tied up. The mouth of the net was extended by means of the long heavy beam, and the beam had at each end a large iron 'head' or runner, so shaped as to slide along the sea-bottom, carrying the beam at a height of about 4½ feet. The bridle coming from the steel-wire cable was attached to the iron trawl-heads. The upper part of the mouth of the net was attached closely to the beam, but the part which came to the ground, and which was weighted, and termed the ground or sole rope, was considerably longer than the beam. The result was that when the net was fishing the ground-rope swept the bottom in a long curve, while the beam and attached upper net had already passed over the ground stirred. The practice commonly was to drag the net for about six hours; and as each trawler carried two nets, one on each side of the boat, one net went down when the other came up. The intervals between hauls were occupied by sorting out the fish, packing, rearranging the gear, and in snatching meals or sleep. Operations went on day and night, and almost in any weather.

This system of trawling goes on still, but an almost universal change in the make of the trawl-net has been adopted. Instead of the beam trawl, the net now used is the otter trawl, so called from the manner in which the mouth is kept extended. The old trout-poacher's 'otter' board is weighted along one edge, so that it floats edge up. One man sails it into the loch to be fished, while his accomplice gently pulls upon a line attached by a traveller to the side of the board. To the line fly-hooks are attached at intervals. When the pull comes upon the line, the board glides outwards at an angle away from the man pulling. The same principle has been adopted in the otter trawl. There is now no beam or iron heads, but, in place of these, an otter-board is placed at each side of the mouth of the net, and to this otter-board the bridle from the cable is attached. Each board, when the pull comes upon the bridle, tends to fly outwards from the centre of the net-mouth, and in this way a sufficient strain is kept to hold the mouth open. With the removal of the beam and iron heads the gear is now much lighter to work, and, there being no difficulty about the longest possible beam which can be brought to the rail of the vessel, the otter trawl is much larger than the

old beam trawl could be. It has been estimated that the modern otter trawl, worked by a modern steam-trawler, is eight times as efficient as a catching engine as the old beam trawl used to be. This naturally makes a vast difference in the results of trawl-fishing in certain localities.

Other methods of fishing have become rather more attractive or remunerative, but trawling-vessels themselves are becoming more powerful and more efficient in every way.

In the general competition of this branch of the industry a new system of organising operation in trawling has also come about. This is known as the fleet system, since vessels are organised in fleets. In the early days of English trawling the sailing-vessels employed worked singly, the crews being exclusively interested in their own catches. After about a day and a night's fishing the vessel returned to land her fish. The practice of taking out ice and, in some cases, of cleaning the fish caught lengthened to a considerable extent the time during which it was possible for a trawler to remain at sea; but if no very great success attended a boat's fishing, the skipper had inevitably to choose between going to other grounds on the chance of filling up a cargo, and thus taking the risk of the fish already caught going stale, or of returning with a short catch.

To equip steam-vessels properly involved considerable capital, and companies began to be formed owning several vessels. From Grimsby and Hull especially large companies sprang up. The next step was the natural one of arranging to keep the fleets of vessels at sea for considerable periods, and to have special carrying vessels told off to bring the fish to market. The operation of transferring boxes of fish from one vessel to another in a rough sea is not always an easy matter; and it commonly happens that the vessels dare not go alongside each other for fear of damage, and the boxes of fish have to be put overboard from the trawler and hauled to the carrier, somewhat after the fashion in which warships are now enabled to coal at sea, even under way.

To save expense of coal the carriers commonly sail to the nearest ports, but the marketing of the fish is largely regulated by the considerations of prices and transport on land. London being, of course, the great objective, Grimsby, with its splendid docking accommodation and easy access to the chief fishing-banks of the North Sea, has held undisputed first rank as the trawling centre.

Catches made far north, as round Iceland, are commonly landed at Aberdeen; but many Grimsby trawlers consider the distance between Aberdeen and home insignificant, and steam on to the southern port.

From the south of England trawlers have explored the waters of west France, the Bay of Biscay, and even the coasts of Spain and Portugal, but in experience these southern grounds have not been found to be so good as the colder waters of the North Sea.

The development in the north, the Iceland and Farøe fishing, brought halibut and skates of huge proportions to the 'pontoon' of Grimsby and the fish-market of Aberdeen. A wide region was thus brought under constant toll for the markets of the country; and to comprehend the never-ceasing abundance of our fish-supply in these demersal fishes alone, apart altogether from the separate, and even larger, industry of the herring-fishing, one has to view the early morning display on the quays of our principal fishing-ports; the crowd of vessels; the busy throng of grimy men, strong from the breath of the sea, as they swing their catches ashore; the constant hustle of those who arrange the lots for purchase, or remove them after sale;

the auctioneers, after the ringing of a bell, rapidly mounting a fish-box and disposing of the lots to the surrounding crowd of buyers; the same scene repeated at many points simultaneously. One has to realise that this goes on every morning, and that the signs of it have almost vanished before many people are well out of bed. Incredible numbers of fish are purchased daily—haddocks, cod, ling, whiting, saithe, torsk, conger, hake, halibut, plaice, soles, lemon soles, flounders, dabs, witches, turbot, brill, skates and rays, gurnards, and many commoner sorts.

In England, although the fleeting system is in full force, there are still a large number of sailing-trlawlers. Indeed, the economy of the sailing-vessel is sufficiently marked to make the sacrifice of mobility worth while. The sailing-drifter—i.e. the herring fishing-boat—is rapidly declining in both England and Scotland.

Line-fishing.—Another method of taking bottom-feeding fish is lining—that is, the sinking of lines, sometimes as much as seven miles long, to which at intervals short lines (two or three feet) bearing baited hooks are attached. The lines are commonly shot at night, and their position marked by buoys, so that they can be picked up next morning. Time was when a large industry was carried on by line-fishing off the east coast of Scotland, and the industry is still well in evidence, but it has largely given place to a system of fishing herring all the year round. Formerly a crew used to fish lines at one part of the season, and nets for herring at another. With the power of going to greater distances, however, the practice has steadily grown of following the herring wherever the herring is to be found. Mussel-scalps are in consequence largely now left to themselves, as the need for bait is by no means so great as it was.

Demersal and Pelagic Fish.—Fish that live mainly on the sea-bottom, and are taken by trawlers and liners as opposed to herrings, mackerel, and other 'pelagic fish,' and to shellfish, are called 'demersal fish.' Of these there are various subdivisions, and the term 'prime fish' is meant to include soles, turbot, and brill. Of other demersal fish, haddocks, cod, and plaice give greatest total weights. Important also in the markets are hake, dabs, coalfish or large saithe, skates, and ling, mentioned approximately in descending order.

The trawler catches the greatest number of haddocks. The destruction of the haddock was at one time laid to the charge of the trawler, but time has repeatedly shown the singular fluctuation in the catch of this species; indeed, on the east coast of Ireland haddocks had almost disappeared before trawlers came to that locality; and after the trawlers had been at work for some years, the catch of haddocks again became good.

The plaice is the most numerous flat-fish, and that which is generally represented by the highest total weight. Nevertheless a great development has come about in the catch of halibut by steam-liners.

The catch of turbot shows a steady decline, and many of the fish landed are so small that they cannot have reproduced their species before being caught.

It has been by the development of trawling that the much-prized sole has been introduced to the English market. This fish is not captured by other means, nor is it captured to any extent in Scottish waters. All other bottom-feeding fish are also taken by the trawler, so long as the fish are from a bottom suitable for the working of the trawl-net, for this method cannot be employed on hard, rocky bottoms.

Of 'pelagic' fishes—those that habitually swim near the surface—the most important are the

herring, the mackerel, the pilchard, and the sprat. These are taken mainly by drift-nets, to some extent by seines; but during the season herring and mackerel are also trawled.

Drift-fishing.—Drift-nets are oblong nets fastened together in a long series, buoyed above so as to float vertically in the sea. The series of nets, or 'fleet,' as it is called, is fastened at one end by a rope to the boat from which it is worked, and nets and boat 'drift' or 'drive' with the tide. The nets are shot at right angles to the current of the tide, and the fish strike against them. Their heads passing through the meshes, the fish can neither swim forwards, because their bodies are too large to pass through, nor backwards, because their gill-covers are then caught by the string of the net. The nets used for herrings and pilchards differ only in the size of the mesh. For herrings they have 30 to 32 meshes to the yard; for pilchards, 36 to 38. They are supported by a rope along the upper edge, and when shot are connected by tying the ends of these ropes together, and along this rope pieces of cork are attached to keep it uppermost. To the same rope, at each end of each net, are attached bladders of considerable size by means of a few fathoms of strong line. As these buoys float on the surface of the water, the nets are suspended below at a distance depending on the length of the buoy-lines, and varying according to the depth at which the fish are expected to occur. Mackerel-nets have a larger mesh—25 or 26 to the yard—and are worked differently. The 'back' of the nets is kept at the surface, floats being fastened directly on to it, and a separate rope, called the 'foot-line,' is connected to the 'back' of each net by a long connecting-line. The foot-line therefore sinks to some distance below the bottom of the nets. The reason for this is that mackerel usually swim quite near to the surface, and as the line running along the 'back,' is liable to be broken by passing vessels, it is necessary that the nets should be attached to the foot-rope, which sinks to a safe distance, and by which the nets are hauled in. The seine is a single, continuous net, with a cork-line above and a leaded line below, attached at each end by means of these lines to a long rope. In Britain the seine is always worked from the shore. It is shot from a rowing-boat in a large semicircle, and then by means of the two end ropes is hauled on shore, or the ends are brought together so as to enclose the fish.

In drift-fishing, as in trawling, great changes have occurred. The magnificent fleets of sailing-boats may be said still to exist, but herring-fishing is now best carried on by means of the steam-drifter, while there can be no doubt that the motor-engine has come to stay. Steam-drifters were, as first used, merely seaworthy wooden boats of the approved type fitted with steam-engines. In recent years all the best drifters have been of steel. Before steam was introduced to propel these herring-boats it was very largely used for hauling the nets. All the large Zulu boats of 60 feet length had their steam-capstans. The motor-engine with paraffin fuel came into use in the year 1901. At first the motors were auxiliary to sails. For use in the larger class of fishing-vessel, and especially in the herring or mackerel drifter, the motor has certain advantages, in that the engine takes up little room, coal-bunkers are dispensed with, fuel is not burnt when the boat lies at her nets, since the engine can be started up at short notice. It appears more and more evident that fishermen will not be content with a motor-engine as a mere auxiliary to a sailing-boat for use in calms. If a motor-engine is installed, it must be capable of driving the boat in all weathers, as a steam-engine can. The real need, however, is a serviceable motor-capstan for hauling nets and

other gear. With the boat lifting or rolling in a sea-way the strain on a capstan is almost invariably unequal, and often violently so. With a steam-capstan, the operation of winding-in will cease with a violent jerk or with pressure too great for the power of the engine, but will recommence when the jerk is past or the pressure lessens. In the case of the motor-capstan of any ordinary type, not only does the operation of winding-in cease, but the motor-engine is stopped altogether. In recent models of motor-capstans attempts have been made to transmit power through hydraulic pressure, compressed air, or electricity, so as to get a more elastic result. Paraffin rather than petrol is used in fishing-boats, and the use of crude oils has also been introduced.

The *herring-fishing* in Scotland can be roughly divided into winter fishing, during the first three months of the year; the early summer fishing in April, May, and June; and what is termed the great summer herring-fishing, which continues from 1st July to the end of the year. The movements of the herring, and the extraordinary fluctuations of the industry in certain localities, are factors well recognised by the fishing community. Places like Lerwick, Wick, and Fraserburgh exist very largely by reason of the herring-fishing. In Lerwick, indeed, within a lifetime, a complete change has taken place in the whole appearance, as well as in the size and characteristics, of the town. In twenty or thirty years, from being a natural harbour where a quaint, little semi-Scandinavian town, with its quiet, hospitable, thrifty people, carried on its remote occupations, and where one or two of the old six-oared boats which used to go to the 'haaf,' or distant fishing, could still be seen, where the greatest excitement of the year was the arrival of the Arctic whalers to pick up their crews before finally turning their backs upon civilisation and home, the place became a huge herring-fishing centre, with miles of curing-stations, vast stacks of barrels, and well-constructed wharfs, where in the summer-time all is bustle and noise. The harbour is packed with steam and sailing drifters, while steamers of several European nations come with coal, barrels, salt, and trade of varied sorts, to sail away loaded with herrings. Fishermen from France and Holland find notices at the post-office in their own languages, and a daily auction in a well-appointed building disposes of the silvery hords. The great development has been due largely to the increased catching-powers of the boats used. The small boats and the boats dependent upon wind alone could not carry on a regular fishing about a hundred miles from land as the steam-drifters now do. It is the story of the trawlers over again. Distant waters have been explored, and huge shoals of herrings previously unthought of have been made to yield their share to the market.

The winter fishing is carried on on the west coast and certain parts of the east coast simultaneously. On the west coast the fish frequently come close inshore, and enter the sea-lochs in great numbers. Early in May the Stornoway fishing begins, and this includes the fishing off all the outer isles. The boats then go north to Shetland, where, right in the north of the islands, at Balta Sound, a great fishing has developed, thanks first of all to the enterprise of Dutchmen. From Balta Sound begins a southward movement of the boats, Lerwick, Orkney, Wick, Fraserburgh, Peterhead, and so on, until by late autumn the fishing winds up at Lowestoft and Yarmouth. While English boats, even from Cornwall, come all the way to Shetland to share in the bountiful supplies of the herring, the Scottish boats return the compliment by following the shoals down the English coast. A considerable number of

Scottish boats also go to Ireland for the herring-fishing there.

It is believed by the fishermen, and very many others, that the well-defined movement of the shoals, and of the boats, each year is one continuous migration of the fish; that shoals do not appear separately in the north, and at a later date in the south, but that the shoals migrate just as the boats follow; that, in other words, these shoals swim from the outer isles round the north of Scotland by the Orkneys and Shetlands, and then down the east coast. In support of this view it has certainly been ascertained that the currents in the sea move in precisely this direction, and that, therefore, there is reason to believe that the minute creatures, such as free-swimming Crustacea, which form the food of the herring are floated from the west, through the Pentland and the northern isles, and thus round into the North Sea.

With the movements of the fishing-fleets go the buyers and the army of those who cure and pack. Thousands of women and girls are employed in gutting and packing herring, many of them being Gaelic-speaking girls from the Highlands. To house, control, and provide for so great a company is in itself quite an undertaking, but they are a hard-working, cheery, and, on the whole, very respectable class.

To encourage the proper curing of herring the original Board of White Fisheries, the progenitor of the present Fishery Board for Scotland, was instituted. The British government agreed to pay a bounty of four shillings per barrel for herrings cured to the satisfaction of the board. This was between the years 1809 and 1826. The supervision of the curing of the herrings was organised by the board, and officers were sent to all the principal curing centres. A brand was put upon the barrels passed by the officers, which brand, becoming a guarantee of quality, became greatly appreciated in the foreign markets, and a great part of the herring cured has always found a market abroad. By 1830 it was deemed no longer necessary to pay the bounty, and this was accordingly abolished in that year. In 1859 a small fee of fourpence a barrel was charged for the privilege of having the government brand of quality, although there was no obligation to have the brand. That the system was altogether successful—although some large curers preferred to continue the use of their own private brands—is shown by the fact that from the small fees named the Fishery Board for Scotland, which came into existence in 1882, and which will be referred to later, paid into the Exchequer a sum of between £7000 and £8000 from this source alone, and was able by this means to develop a complete service of vessels for the protection and regulation of the fishing-fleets. Unfortunately, altered views arose as to the proper curing of herring, and altered methods brought about different results in the market. Fish were oversalted or undersalted, complaints arose very largely from Germany, and confidence in the guarantee of the brand was to some extent destroyed. The income from branding fees fell off. Much has since been done to restore confidence. That the existence of the brand finds favour is well evidenced by the fact that both England and Ireland followed the lead of Scotland in this matter.

The method of trawling for herrings has also come into some prominence in the twentieth century. An adaptation of the otter trawl, so that it can be used for the capture of pelagic fishes, has been chiefly carried out in England, the vessels hailing from the east coast trawling-ports; but Aberdeen trawlers have also to some extent tried the method. Drift-net fishermen have been loud in outcry against it.

The great majority of steam-drifters and sailing herring-boats, as well as boats used in line-fishing in Scotland, are owned by the fishermen themselves. Vessels are acquired by fishermen in various ways: a skipper, or a skipper and his family or immediate friends, become owners by purchase. If they cannot raise money enough for their purpose, a loan is got from a bank after some large firm of fish salesmen or a general merchant has consented to become cautioner. The former sell the fish they catch; the latter supply them with their stores, including nets, coal, oil, &c. The cash credit is worked on the principle of an overdrawn bank-account; all the boat's receipts are paid in, and interest is charged on a day-to-day balance. At the end of the fishing season the fish salesman or merchant is paid, and the surplus is divided into three shares—one credited for the boat, one for the nets, and one divided amongst the crew. Each member of the crew contributes so many nets to the fleet of nets used, and the nets' share is allocated according to the number contributed. The boat's share is used to pay off the loan for the purchase. All the crew of a drifter may not be 'share men,' in which case the extra hands are simply paid a weekly wage, as the engineer, the stoker, and the cook are. The above method of borrowing is common along the southern section of the east coast of Scotland. In the Moray Firth it is common for fishermen to mortgage their houses in order to raise the money to purchase, or the money may be raised partly by loan and mortgage from the bank, partly from a salesman, and partly from the boat-builder in allowing part of the purchase price to remain on second mortgage.

The herring-fishing of England has in recent years taken a far more prominent place than formerly. In the year 1912, in respect both of quantity and quality of the herring, the industry surpassed all previous records, and for the first time the landings surpassed in bulk the landings of the Scottish ports. In 1913 the English herring-fishing rose still further, since it surpassed the Scottish not merely in bulk, but also in value. The distinction between English and Scottish results is, however, more local than national, since, as already stated, a very large number of Scottish fishermen contributed to the English totals at Lowestoft and Yarmouth.

Mackerel-fishing is carried on in the North Sea off the east coast of England, in the Irish Sea and the southern waters of Ireland, in the Bristol Channel, and in the English Channel.

Like the herring, the mackerel swims in shoals, and these shoals appear and disappear in a somewhat extraordinary manner. From researches into the movements of this fish, it is ascertained that a more or less definite series of migrations may be traced. In the northern parts of the North Sea catches are made from December or January to May; while in the southern parts of the North Sea the shoals appear first in April or May, disappear in June or July, and reappear in the period from August to November. Those shoals which are found in the northern parts are found some distance below the surface, and caught in trawl-nets. The southward movement is accompanied by a rising of the shoals towards the surface, which is attributed to the approach of the spawning season. The spawning takes place chiefly in the southern portions of the North Sea, and not far from land. The eggs of the mackerel float. The eggs of the herring, on the other hand, are laid upon the bottom, and become firmly attached to stones and other hard substances. After spawning in the summer months the mackerel apparently searches actively for food, and the shoals scatter freely over the great banks of the North Sea, and are caught by means of drift-nets in the vicinity of

the Great Fisher Bank. Some of the shoals appear then to move northwards, while others move in a south-west direction and enter the English Channel, and by the end of autumn these shoals disappear.

The mackerel-fishing of Ireland is one of the most important branches of the fishing industry, and here again there is a spring and an autumn mackerel-fishing. The fish are largely cured for the American market, where considerable competition exists with the produce of the Norwegian spring mackerel-fishing. The price of fresh mackerel in the London market is generally considerably above the prices of cured in America, and there is a natural inclination towards the quick transport of such fish as can be sent to London in the fresh state. Mackerel must be got quickly to market to retain good quality, and the centres of fishing which are farthest from London are not likely to show a decline in curing so long as the stock of fish continues. The autumn fishing in Ireland is the more important.

The *pilchard-fishing* of the south and west coasts of England seems for some reason or other to be suffering a decline. This is especially so on the west coast, where the quantities landed have now shrunk to an insignificant figure. Devon and Cornwall are the headquarters. Great quantities have been taken in the past. The fish, being very oily, are subjected to pressure before being cured. They are almost all sent to the foreign market. The old method was to catch the pilchard by means of large seine nets, which were dragged to shore. The direction in which the shoals were heading could be best observed from the cliffs on shore, and the regular practice was for the boats to be rowed under the direction of signals from the cliffs. When a large shoal was captured and brought safely to shore, the seine was allowed to remain in the shallow water, while a smaller net, called the tuck seine, was used to remove the fish as they could be dealt with. In this way one or two days might elapse in securing the total catch. Now the old picturesque methods have largely given place to the use of the drift-net, as in herring and mackerel fishing.

Another pelagic fish which swims in shoals, and furnishes a considerable fishing, is the *sprat*. This beautiful little fish is chiefly caught in winter when it enters estuaries. In this respect it is like the sprling or smelt and the shad.

Ports.—In England most of the fishing-ports are of large size, where a certain amount of commercial shipping is already provided for. This is true also in Scotland in the case of such ports as Aberdeen or Leith, but increased harbour and docking accommodation is needed in the interests of the herring-drifters, which sail very largely from the small towns along the shores of the Moray Firth and open east coast. Harbourage being found insufficient, fishermen are often forced to keep their boats at a considerable distance from their homes, and especially when it is necessary to lay them up in the winter months and for repairs. This involves a great additional cost, not only in dock charges, but in travelling by rail. This rather pressing question has been taken up by the Fishery Board for Scotland, which, in addition to moneys usually available for harbour building and repair, has obtained grants from the Development Commission. It has been found at the same time that the tendency of modern fishing is to concentrate in the matter of harbourage and markets, so that certain places of former importance have come to be neglected, while great pressure is put upon others. Large sums have been spent, therefore, on those harbours which seem to be drawing the industry of the future, such as Buckie, Macduff, Fraserburgh, and Wick, but a large number of other ports have

also been provided for. In connection with the prosecution of the herring-fishing the Fishery Board has instituted a system of official telegraphic information between ports for the guidance of fishermen. Full statistics have long been collected and published by the board.

Eel-fisheries.—In certain localities of Ireland the eel-fisheries are of the greatest value, surpassing in this respect the salmon-fisheries. The eel enters fresh water from the sea as an elver of a few inches long, and the length of time it may remain in fresh water has been ascertained to vary very greatly—from two or three years to as many as twelve years; indeed, if by some accident the return to the sea be cut off, or if, as is so well known, the eel climbs to some almost inaccessible locality—and space would fail to tell of the extraordinary places in which eels have been found—the period during which life may be continued in fresh water is indefinitely prolonged. It also appears to be the case that a considerable proportion of so-called fresh-water eels never come into fresh water at all, but frequent the shallow bays and estuaries of the coast. During the time which may be spent in fresh water the eel does not spawn. For this a return to the sea has to be made, and it is this return from lakes and ponds which is taken advantage of for the capture of the fish, since the eels usually 'run' at stated times, and for the most part during dark nights in autumn. See EEL for life-history.

The most successful methods employed are by the construction of partial barriers or weirs in the rivers. These barriers are made of stone in the form of permanent weirs, with carefully defined gaps, or 'eel eyes,' through which the eels have to pass; or they may be constructed of wattle; or eel-nets may simply be placed close together attached to a series of posts sunk firmly in the river-bed. The eel-net is a very long, tapering contrivance of stout cord but fine mesh. It exactly fits the eel eye, and streams freely out in the rush of water which comes from the eye. The end is closed merely by means of a lashing and pin, and close beside the net is placed a live box, into which at intervals the fishermen throw the end of the net after releasing the lashing, so that the contained eels fall through the hatchway of the store-box. In the construction of eel-weirs in a salmon-river care is of course taken that a space be left for the ascent of the king of fishes. No ascending salmon can possibly be captured in the eel-nets, since the latter take only descending fish. In practice, the eel-fisheries and the salmon-fisheries not infrequently belong to the same people. The Limerick district and the Coleraine district—the Bann—form, perhaps, the two most important centres. Lough Neagh is netted and fished by means of set lines also. Other well-established eel-fisheries are at Ballina, Belleek, and Galway.

Pollan.—In speaking of eel-fishing, so much identified with Ireland, we may mention the marketing of another fish which is exclusively Irish. The pollan is found in Lough Neagh, and another pollan is found in Lough Erne, and yet another in the lakes of the Shannon district. In appearance the fish is very like a herring, and it is frequently called the fresh-water herring. In reality it is a member of the salmon family, and has the distinguishing adipose fin of the Salmonidae. The Lough Neagh pollan is most abundant, and it is in this, the largest lake of the British Isles, that the chief fishery is carried on. In Scotland, the vendace of Lochmaben and the powan of Loch Lomond are closely akin to the Irish pollan. The vendace is now comparatively scarce; but the powans of Loch Lomond are very numerous, although not marketed. The fish can be taken only by net.

Crab and lobster fishing is carried on all round the

shores of the British Isles. The largest examples come from the western portion of the English Channel, Devon and Cornwall. Since the lobster is of slow growth, and since the female carries her eggs for several months, there is some difficulty in regulating the catching of these crustaceans. The eggs of the lobster are largely used in the making of sauces, and by the capture of 'berried hens,' as the females with eggs attached are called, in large numbers, the stock of lobsters has sensibly diminished in several localities. The prohibition of the taking of lobsters under the length of eight inches does no more than keep immature and almost unmarketable sizes out of the market. In the encouraging of lobster-fishing, the best results seem to follow a more systematic collection and improved transport. Lobsters can be conveniently kept alive to suit conditions of the market, and recent operations in this direction show that lobsters can breed freely in captivity if they are kept under perfectly natural conditions. A store in the sea, of the kind indicated, was first started with success at Roscoff, in Brittany. Similar operations are now carried out in Scotland. As regards money value in England and Wales, the crab is much more remunerative than the lobster. Both are taken in 'pots' or traps, dome-shaped cages with funnel-like in-turned openings. Shrimps are caught by push-nets, hose-nets, small-meshed trawls, and shanks. The hose-net is a cylindrical net, fixed to a stake. The shank is like a trawl, with a wooden base instead of a foot-rope.

For salmon, whale, seal, and oyster fisheries, see articles under these headings, as well as PEARL and Ceylon. See also PRESERVED PROVISIONS; J. L. Jenkins, *The Sea Fisheries* (1920); W. Radcliffe, *Fishing from the Earliest Times* (1921).

Fisher's Hill, in the Shenandoah valley, Virginia, 30 miles S. of Winchester, is memorable for Sheridan's victory over the Confederate General Early, on 21st September 1864.

Fishes, a great class of backboneed animals, rising above the lowly vertebrates—Ascidians, lancelet, and round-mouths—on the one hand, and leading on to the Amphibians on the other. The Tunicates or Ascidians (q.v.) are indeed numerous, but they are mostly degenerate; the level attained by the lancelet (*Amphioxus*, q.v.) is represented only by a single genus; the round-mouths or Cyclostomata (q.v.) are few in number and partially retrogressive, but the fishes have been and are successful. In the possession of the characteristic vertebrate axis and central nervous system, in general compactness and co-ordination of structure, in their external armature of scales, and in their great fecundity, fishes have an easy pre-eminence over their invertebrate inferiors, while as successfully adapted forms they hold as firm possession of their own special medium as birds do of theirs. Their success may be read in the immense number of individuals, species, and genera, not only now, but in the great reons of the past; in the geological record which shows how the Cartilaginous Fishes (q.v.) or shark tribe have persisted strongly from Silurian times, or how the decadent Ganoid (e.g. sturgeon) order is followed by a yet richer predominance of the modern Bony Fishes (q.v.); and, furthermore, in the wealth of adaptive specialisation which distinguishes so many, and which in the case of the 'double-breathers' or Dipnoi prophesies, in the evolution of lungs, the important transition from water to *terra firma*.

Literary History.—The history of the study of fishes finds its beginning as usual in the work of Aristotle (384–322 B.C.), who distinguished over a hundred Ægean species, is perfectly clear in dis-

criminating them from cetaceans and invertebrates, and records a surprising amount of information in regard to both their structure and habits. As with other departments of natural history, so ichthyology, in spite of its stable foundation, remained virtually unprogressive for eighteen centuries. In the 16th century at length Belon began to collect both specimens and information; Salviani, the physician of three popes, published an illustrated work characterised rather by artistic merit and popular interest than by scientific value; while Rondelet, as a medical anatomist, ventured further into structural details than either of his contemporaries. In the next century the classifying genius of Ray and Willughby achieved great progress, and the establishment of order was continued by Artedi, whose results were edited by his fellow-student Linnæus. The labours of the Linnæan school were ably continued by Bloch and Lacépède, both working during the critical period of the French Revolution. The anatomical investigations of Alexander Monro, embodied in a classical folio, led on to the great *Histoire Naturelle des Poissons* begun by Cuvier, continued by his pupil and collaborateur Valenciennes, and finally left unfinished in 1845 at the twenty-second volume. The virtual discovery of the Ganoids by Agassiz, their investigation by Johannes Müller, the separation of the Dipnoi, the Cyclostomata, and Amphioxus by the same anatomist, and the discovery of Ceratodus, described in 1871 by Günther, were ichthyological events of great importance. Within late years, apart from the vigorous prosecution of anatomical investigation, the study of the development of fishes has yielded to such workers as Balfour, Parker, and Semper results of fundamental import; our knowledge of fossil forms has been enriched by the researches of Traquair and Smith Woodward; the theoretical aspects of structure have been especially investigated by Dohrn; while the high-water mark of general ichthyology is represented in the British Museum Catalogue of Fishes and other works by Günther.

General Survey.—After excluding the lancelets and the Cyclostomes as survivors of far-removed ancestral forms, there remain three sub-classes of fishes properly so called—(1) the cartilaginous Elasmobranchs, (2) the Teleostomes, and (3) the Dipnoi. Besides these there are some extinct divisions of uncertain position, notably the ancient Ostracoderms or Hypostomes—e.g. *Pteraspis* and *Pterichthys*. (1) The Elasmobranchs stand well apart from other fishes. They include sharks and dog-fish, skates and rays, some extinct orders, and the divergent Holocephali, such as *Chimaera monstrosa*, 'the king of the herrings.' (2) The Teleostomes include the archaic Crossopterygii, now represented only by two genera, *Polypterus* and *Calamichthys*; the Chondrostei, such as the sturgeon; the Holostei, such as the Bony Pike (*Lepidosteus*) and *Amia*; and the great host of Teleostei, which comprises, for instance, all our common food fishes. (3) The Dipnoi or double-breathers have only three representative genera, widely separated in geographical distribution—*Ceratodus* from Queensland, *Protopterus* from West and tropical Africa, and *Lepidosiren* from the Amazon. The Teleostomes other than Teleosteans are often called Ganoids.

General Characters.—Like other vertebrates, fishes possess a segmented body, well indicated by the disposition of the muscles; a dorsal nerve cord, swollen anteriorly into a brain; a dorsal axis or notochord, more or less completely replaced by a genuine backbone; a set of respiratory clefts on the pharynx, which here persist and are associated with gills; a ventral heart; and eyes which arise for the most part as outgrowths of the brain. But

their prominent peculiarities are associated with the three sets of structures—scales, fins, and gills. The scales are usually produced by the inner layer of the skin, the dermis, and are covered over by the epidermis; the unpaired median fins are always supported by skeletal rays, and the paired lateral fins or limbs are never in any definite sense fingered; the gills are retained throughout life. Technical negative characters are the absence of an allantoic bladder and of a true inferior vena cava.

Structure and Functions.—The most characteristic form is that of herring, haddock, salmon, and the like, an elongated, laterally compressed spindle, thinning off like a wedge posteriorly, and obviously the result of, or an adaptation to, the mode of aquatic progression. But the skates are flattened from above downwards, and the bony flat-fish, such as plaice, are compressed laterally; the eels, the ribbon-fish (e.g. *Regalecus*), the band-fish (*Cepola*), the pipe-fish (*Syngnathus*), are much elongated; while the globe-fish (*Tetrodon*, *Diodon*), coffer-fish (*Ostracion*), and sun-fish (*Orthogoriscus*) are more or less globular. The flat-fish live at the bottom; the elongated forms have a serpentine habit of creeping through crevices; the globular forms are sluggish, and may float apparently passive in the water. Prominent external characters, to be presently noticed in order, are the nostrils and eyes, the openings of the gill-cavities, the various kinds of scales, the paired and the median fins, the lateral sensory lines, the openings of the gut and urinogenital organs, the symmetrical or asymmetrical shape of the tail.

The skin has numerous unicellular glands or goblet-cells which secrete mucus. Only in the Dipnoi and in some poisonous fishes do we find multicellular glands as in higher animals. In most cases the epidermis is a delicate transparent layer. The dermis is without muscular elements. Pigment cells under nervous control are common in the skin—e.g. in plaice, which thereby more or less rapidly alter their colour to suit their surroundings. The colours of fishes are often resplendent, and usually depend on the presence of lipochrome or fatty pigments, greatly enhanced by structural peculiarities and by the presence of a silvery foreground of guanine in the epidermic cells (see PIGMENT). As in the 'gemmeous dragonet,' the males are at the breeding season often transformed in brilliant 'wedding' robes. The exoskeleton varies very widely, and so inconstantly that Agassiz' attempt to base a classification on the nature of the scales has been universally abandoned. Cartilaginous fishes are characterised by large or small skin-teeth, 'dermal denticles' or 'placoid scales,' forming the spines of a thornback or the shagreen of a shark. They are based in bone, cored with dentine, tipped with enamel, and are similar in structure and development to the true teeth of the mouth. The bone and dentine are formed from the cutis or dermis, the enamel from the epidermis. Spines occur here and there in other fishes, but flat scales predominate. These lie in sacks of the dermis, sometimes fuse together into plates, are covered with glistening ganoin in the bony pike and some other Ganoids, but are soft overlapping plates in the common Teleosteans, where they are called cycloid or ctenoid, according as the free margin is entire or toothed. From the rings of growth on the scales and bones and ear-ossicles, the age of the fish can often be read with reliable accuracy.

Skeleton.—The oldest vertebrate skeletons were cartilaginous, and the greater part of every individual framework has to recapitulate this stage. Very early, however, and at first in scales and teeth, bone was developed; but many of the older types of fishes are only slightly or very partially beyond

the cartilaginous level. As in all other vertebrates, the longitudinal axis begins as a rod of cells on the dorsal wall of the gut. This notochord, itself of endodermic origin, becomes surrounded by a mesodermic sheath, and when a genuine vertebral column is established it is always by the predominance of the sheath over the enclosed rod. In some Elasmobranchs, in gristly Ganoids, such as the sturgeon, and in Dipnoi, the notochord with its sheath persists undivided; while in other fishes vertebral bodies, bony or otherwise, are established. The typical fish vertebra is concave at both ends, and every two adjacent vertebrae thus enclose a wide space in which the remains of the notochord persist.

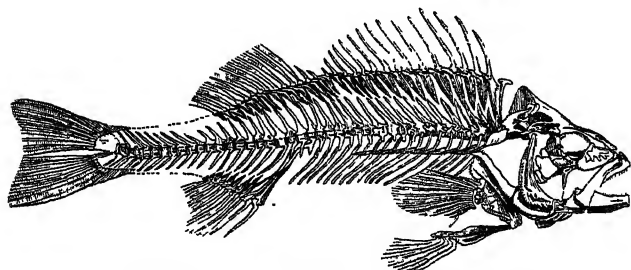

Fig. 1.—Skeleton of the Perch (after Gunther).

The bony pike (*Lepidosteus*), one of the bony Ganoids, stands alone in having vertebrae hollow behind but convex in front. The dorsal axis protects the spinal cord, which lies above, by forming a continuous tunnel, or by a succession of 'neural arches.' In the tail region 'hæmal processes' similarly surround the blood-vessels, and the external ends of neural and hæmal arches may come to be associated with dorsal and anal unpaired fins. The tail-end of the axis is usually bent upwards, but is straight in Dipnoi and a few others, and is surrounded by a special bony sheath in many Teleosteans. Thus, we have an asymmetrical tail in Elasmobranchs and some Ganoids, a perfectly symmetrical tail in Dipnoi, and a superficially symmetrical tail in most Teleosteans, and in some Ganoids, where the way in which the rays are disposed disguises the real upturning of the axis. When the notochord remains undivided the ribs are cartilaginous, and in all fishes they are very simple.

To understand the skull it is necessary to recognise its triple origin: (1) The brain is at first enclosed in a cartilaginous box, with which the gristly capsules surrounding nose and ear become at an early stage intimately associated. This chondrocranium or gristly brain-box is a truly axial portion of the skull, corresponding to a comparatively large number of segments (see SKULL). It is always well developed, and remains entirely unossified in Elasmobranchs alone, being in other fishes more or less modified into bones. (2) But, in the second place, what are called skin bones have to be taken into account. These dermal ossifications, 'membrane,' or, better, 'investing-bones,' probably had their historic origin in the fusion of bony scales. They are greatly developed in bony Ganoids and in Teleosteans, and more or less cover the chondrocranium on its roof, floor, and sides. (3) Lastly, there depend from the skull a series of arches, of which the posterior form supports for the gills, while the anterior form at least the groundwork of the jaws, and may enter into yet more intimate union with the main body of the skull.

Limbs.—The paired fins of fishes are in origin strictly comparable with the arms and legs of higher vertebrates, but their component parts are too simple to be very definitely compared with those of

fingered or toed appendages, such as occur for the first time in amphibians. A typical fin consists of a basal piece, or of several, associated internally with a pectoral, and less constantly with a pelvic, girdle. From the base a large number of rays radiate outwards. A most interesting type, from which some have attempted directly to derive the 'dactyls' of higher forms, is exhibited by the Dipnoi, in which a main axis runs down the limb (see CERATODUS). It seems most probable that the paired fins are concentrations or remnants of a continuous lateral fin extending along each side of the body. Among the many modifications may be noted the enormous pectoral fins of skates, the anterior position of the pelvic fins in many bony fishes, and the transformation of the pelvis into an adhesive disc in the Lumpsucker. As to their use, it must be remembered that the chief organ of locomotion is the tail, and that the paired fins serve to raise and depress the fish in the water, or to some extent act as rudders. In a few cases, as in the climbing perch, they are utilised as scrambling appendages. The pectoral girdle which supports the fore-limb is cartilaginous in Elasmobranchs, Dipnoi, and some Ganoids, but is elsewhere ossified. Coracoid

and scapular portions are distinguishable, while in Ganoids and Teleosteans there is a special development of investing bones. The pelvic girdle is a well-developed hoop in Elasmobranchs, while in Ganoids and Teleosteans, with one or two trifling exceptions, it is absent. The unpaired fins are derived from a continuous fringe seen in the embryo (see fig. 2), and this state occasionally persists. Usually, however, there are several dorsals and anals, and the great locomotor fin of the tail. Sometimes spine-like and all of one piece, some-

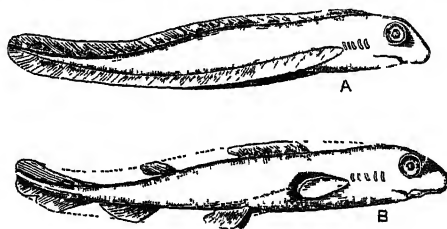

Fig. 2.—The Origin of Fins:

A, showing the undifferentiated embryonic and probably primitive state, with continuous median and lateral fins. B, showing the two dorsals, the caudal and anal unpaired fins, and the pectoral and pelvic paired fins. (After Wiedersheim and Parker.)

times soft and jointed, they afford valuable aids in classification.

Muscular System.—The great muscles of the trunk and tail, which do the work of locomotion, retain a segmented arrangement (as can be very plainly seen even on a boiled fish); and the segments or myotomes are separated by septa of fibrous connective tissue. Remarkable modifications of muscular tissue and nerve-endings form most of the electric organs. See ELECTRIC FISHES.

Nervous System.—The brain and spinal cord are smaller in relation to the body than in other vertebrates. The growing skull outruns what it encloses, and the adult brain thus lies in a relatively large cranial cavity. All the usual divisions of the brain are developed, and in adult life lie virtually in one plane. Ten nerves from the brain, a large number from the spinal cord, and a sym-

pathetic system exhibit their usual relations. See BRAIN.

Sense Organs.—In most fishes a diffuse sensory system is located in the skin. Nerve endings of various kinds occur here and there over the surface, projecting superficially, arranged in definite lines, lodged in pits, or associated with a peculiar system of canals filled with mucus. The sensory structures thus variously arranged are distinguished as 'nerve eminences' and as 'end buds.' The former are very familiar in the lateral lines, one of which runs down each side of most bony fishes, and in the mucous canals which branch so abundantly on skates. The 'end buds' hardly occur in Elasmobranchs, but are abundant in Teleosteans, especially about the head. Near the mouth of the sturgeon, the cod, and other forms are tactile 'barbules.' Important too, though unfamiliar, are the 'eye-like,' 'pearl-like,' and 'phosphorescent' organs on the skin of deep-sea fishes.

The nose sacs lie ventrally in Elasmobranchs, in some of which—e.g. skates—they are connected with the corners of the mouth in a sort of hare-lip fashion. In Ganoids and Teleosteans the nasal sacs lie dorsally in front of the eyes. In many cases each nostril has two openings, and in Dipnoi one of these is within the mouth.

The eyes (see EYE) are usually large, but are destitute of glands and lids. In fishes living in darkness, whether in caves, mud, or the deep sea, the eyes may be rudimentary (see BLIND FISH). The final position of both eyes on one side is a remarkable peculiarity of bony Flat-fishes (q.v.).

As in higher forms, the ear begins as an inturning of the skin, and a canal opening to the exterior in many Elasmobranchs persists as a remnant of this. From the comparatively superficial position of the ear, the waves of sound have not to penetrate so deeply as in higher vertebrates. The ear is largely a balancing or equilibrating organ, but it has been proved experimentally that fishes become aware of vibrations in the water by their ears, as also by their lateral line and skin. Inside the ear are the usual otolithic accumulations, sometimes soft, sometimes stone-like. In many Teleosteans, as may be conveniently seen in cod or haddock, one of the otoliths is strikingly large.

Intelligence and Emotions.—Fishes are not usually credited with many emotions or with much intelligence, but their natural life has not yet been sufficiently studied to admit of a fair verdict. As it is, anglers know how they become wary and cunning, and keepers of aquaria have recorded many instances of the commoner emotions and of fair intelligence. According to Romanes, their emotions approach those of ants or of children four months old, except that no evidence of genuine sympathy is forthcoming. 'Fear and pugnacity are too apparent in fish to require special proof. The social or gregarious feelings are strongly shown by the numberless species which swim in shoals, the sexual feelings are proved by courtships, and the parental by those species which build nests and guard their young.' The stickleback woos his mate with undisguised passion and amusing coquetry, and guards the nest and eggs with jealous care. The Chinese butterfly-fish or Macropod, besides making an ingenious frothy nest of air and mucus, lifts the eggs into it by enveloping them in a cloud of bubbles. Tamed fishes have been known to become familiar with their keepers, and to answer to certain sounds. In natural life, the angling of the fishing-frog, the spitting of the archer-fish, the leaping of salmon and their careful selection of spawning-grounds, the memory for localities which some are said to exhibit, all indicate that intelligence is not asleep in the fish's brain.

Alimentary System and Food.—The gut of fishes exhibits the usual vertebrate characteristics; but the distinctions of the several regions are often less marked than in higher forms. The mouth has no salivary glands, but, except in sturgeons, some Lophobranchs, and a few more, it has well-developed teeth on various bones. These mainly consist of ivory or dentine, tipped with enamel, and vary greatly in size, form, and mode of attachment. In cartilaginous fishes they rise out of a fibrous membrane which grows over the jaw as the outer teeth are worn away; in the angler (*Lophius*) and some other Teleosteans they bend backwards, and oppose the egress of struggling prey; in bony Ganoids and in Teleostei they occur on branchial arches (pharyngeal teeth), as well as on the usual bones of the skull. The mouth is ventral in Elasmobranchs, but in other cases is terminal, or occasionally upturned. The pharynx opens to the exterior by the respiratory gill-slits; gullet, stomach, intestine, liver, and gall-bladder have

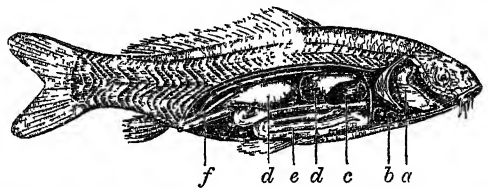

Fig. 3.—Internal Anatomy of the Carp, showing the muscle segments where the skin has been removed:

a, gills; b, heart; c, liver; d, swim-bladder; e, intestine; f, ureters.

their usual relations; in Ganoids and most Teleosteans a large number of 'pyloric caeca' are given off at the beginning of the intestine; the pancreas is often diffuse or absent in Teleosteans; except in the last-named order, but especially in Elasmobranchs, there is a spiral ridge running down the large intestine, greatly increasing its internal surface. In Elasmobranchs and Dipnoi the gut ends in a cloaca or common chamber, into which the urinogenital ducts also open. In other fishes the anus lies in front of and separate from the other aperture or apertures.

The food of fishes is very diverse, from minute Protozoa to whales; they are carnivorous, vegetarian, or virtually omnivorous. Worms, crustaceans, insects, and molluscs and other fishes are important items in the carnivorous diet, in which they are usually voracious and often anything but discriminating. Some swallow mud for its living or decomposing contents; others, again, feed on sea and fresh-water weeds. The food is usually swallowed whole, though some sharks tear their prey into available pieces. Not a few forms manage to swallow other fishes out of all proportion to their own size, and in museums may be seen specimens which have managed to get outside victims even larger than themselves! It has been shown experimentally that fishes are attracted to their food in various ways—by sight, or by odours, or by chemical stimuli in the water.

Circulation.—In all fishes, except the Dipnoi, the heart receives impure blood only. This is driven by the muscular chamber or ventricle to the gills, whence being purified it is collected into the dorsal aorta which gives off arteries to all parts of the body except the head, which receives a direct supply from the most anterior of the vessels returning from the gills. From the body anterior and posterior veins convey the impure blood into the heart, into the so-called sinus venosus, or porch to the auricle. Though the direct work of the heart is solely to drive impure blood to the gills,

it need hardly be pointed out that, as the chief origin of the alterations of pressure which determine the circulation, the heart has its usual, though obviously indirect, systemic significance. Except in the bony fishes, the ventricle is prolonged into a contractile tube known as the *conus arteriosus*; but, except in the Dipnoi, the heart is accurately described as two-chambered. Venous blood from the posterior region passes through the kidneys, forming a renal-portal system, as in amphibians and most reptiles, and there is the usual hepatic-portal system wherein vessels from the intestine pass into the liver. The hepatic veins leading from the liver enter the heart independently of the other posterior veins, and thus there is no strict *inferior vena cava*. In the Dipnoi the circulation has been modified with the acquisition of lungs. The heart receives pure as well as impure blood, and the auricle is divided by a septum. Fishes have the usual lymph system, and the ordinary blood-glands—spleen, thyroid, and thymus.

Respiratory System.—From the pharynx the characteristic vertebrate clefts open to the exterior, and admit of a water current in by the mouth, down the pharynx, out by the clefts. Between the clefts extend the supporting (branchial) arches, and these bear the folds or filaments on which the blood is exposed—in other words, the gills. In the cartilaginous fishes the separate gill-clefts are obvious enough externally; in other fishes the apertures are protected by a fold or operculum, and the partitions which form a series of chambers in skate or shark become more or less reduced. Thus, in the haddock there is one external opening on each side, and the gill-filaments are borne upon arches which are only attached at their extremities. The number of gills or clefts varies considerably; there are usually five in Elasmobranchs, four in Teleosts. The primitive fish probably had a larger number of gill-slits, and *Heptanchus* still survives with seven. In Elasmobranchs and some Ganoids the most anterior of the distinct gill-slits forms the 'spiracle,' opening on the top of the head, sometimes bearing a rudimentary gill, and corresponding to the Eustachian tube in higher animals. In young Elasmobranchs the gill-filaments are prolonged externally through the slits; in the larvæ of *Polypterus* and *Lepidosiren* there are true external (ectodermic) gills like those of a tadpole; in *Protopterus* three external gill-filaments persist in adult life. In the majority of fishes, but not in Elasmobranchs, nor in bony flat-fish such as plaice, there is an Air-bladder (q.v.) or swim-bladder, which arises almost always as a dorsal outgrowth from the gut, and prophesies the lung of higher vertebrates. As the name suggests, its function is in most cases hydrostatic, raising or lowering the fish according to its state of expansion or contraction, and it always receives a supply of arterial blood. In the 'double-breathing' Dipnoi, which gulp air at the surface, the swim-bladder functions as a genuine lung, and the same is true to a less marked extent of a few other fishes. In all Ganoids and in the *Physostomi* section of bony fishes the connection between air-bladder and gullet remains throughout life an open passage; in the other bony fishes (*Physoclisti*) the connection is a solid cord or is altogether obliterated. The sac extends along the back under the vertebral column, and is exceptionally (e.g. *Polypterus*) double like lungs; in four families of Teleostei it is connected anteriorly with the ear by a chain of bones, 'by means of which its relative fullness can be appreciated by the fish.' Some bony fishes—e.g. climbing perch and certain Silurids—have curious accessory respiratory organs, and are able to remain for some time out of the water; and here also may

be noted the dilatible sac which opens into the ventral side of the pharynx in some box or globe fishes—e.g. *Diodon*. See GILLS.

Excretory System.—To the zoologist the kidneys of fishes are of great interest, because it has been possible through the study of their development to reach an approximate elucidation of the 'homologies' or real resemblances in the different parts of the urinogenital system throughout the vertebrate series. Only two general sentences are here permissible. At an early stage a segmentally arranged series of ciliated excretory tubules, or nephridia, make their appearance; they are strictly comparable to the excretory tubes of invertebrates, and a certain unity is thus demonstrable between earthworm and dog-fish. Of these little tubes some form the adult kidney, others the 'Wolffian body' or 'paiovarium,' while others disappear. But, besides the tubules which lie transversely, there is on each side a longitudinal duct with which some at least of the nephridia become connected; this so-called 'segmental duct' is either derived, as the insinking of a skin (ectodermic) groove, or else from the external portion of the middle (mesodermic) layer; on each side it typically becomes double, and forms the reproductive ducts for either sex, but the half which is important in the male is rudimentary or unimportant in the female, and *vice versa*.

Reproduction.—The sexes are almost always separate, but a male organ or testis 'is constantly found imbedded in the wall of the ovary in *Chrysophrys* and *Serranus* (two bony fishes), and the last named fish is said to be self-impregnating.' As in most other vertebrates, occasional hermaphroditism occurs as an abnormality—e.g. in mackerel and herring. The males of bony fishes are usually smaller than their mates, and sometimes very markedly so; in many cases, especially at the breeding season, they are further distinguished from the females by bright colouring. Thus, the male 'gemmeous dragonet' (*Callionymus lyra*) is so flushed with brilliant colour that it was regarded by Linnæus as quite distinct from the 'sordid, dingy female.' The male sea-scorpion (*Cottus scorpius*), usually ill-favoured, becomes gorgeously adorned during the spawning season, and the same is true of a great many forms. In Elasmobranchs the males are distinguished by the possession of copulatory organs or 'claspers.' As the males often fight with their rivals, special adaptations have come to be associated with this habit; of these the hooked lower jaw of the male salmon, so suitable for butting, is perhaps the most familiar instance. In many marine fishes the females appear to be in a very large majority. There are frequently other differences between the sexes, especially as regards the unpaired fins, and Darwin also quotes some cases (especially *Ophidium*) where it seems that the males, and the males only, have the power of producing sounds. See SEX, SEXUAL SELECTION. The ovaries and testes are almost always paired organs, which become large and conspicuous in the reproductive season. In all Teleosts save one, and in the bony pike (*Lepidosteus*), there are ducts continuous with the ovaries; in other fishes the eggs burst into the body-cavity, and are subsequently pressed into the ducts. The male elements usually pass more or less directly into ducts. In most Elasmobranchs, in Ganoids, Dipnoi, and a few Teleosts, there are two openings or 'abdominal pores' from the body-cavity to the exterior.

Most fishes are oviparous, laying the eggs as such, and that usually in great numbers. They are extruded on the bottom—e.g. among gravel—or in many cases are discharged broadcast in the water. A few fishes, such as sturgeon and salmon,

ascend rivers for spawning purposes; while others, like the eel, descend to the sea. The female salmon is careful in the choice of a spawning ground, and in plunging a groove for the eggs among the gravel is said to avoid areas which have been already occupied by her forerunners. In regard to trout, it has been observed that the absence of a suitable bottom may lead to retention of the ova, to consequent disease in the organ, and to an inferior brood the next season. The eggs of oviparous Elasmobranchs are surrounded by a horny case, the so-called mermaid's purse, so often found empty on the beach. This sheath is a product of the middle portion of the oviduct, and often has tendril-like prolongations at the corners, which twine themselves automatically round seaweed, where the embryos are rocked till the time of hatching. Most sharks and a few Teleosts bring forth their young alive. In the viviparous Teleosts the eggs develop in the ovary or in the oviduct; in the sharks, in the oviduct. Two of the viviparous sharks (*Mustelus laevis* and *Carcharias glaucus*) are of peculiar interest in the establishment of a vascular placenta-like union between the yolk-sac and the wall of the oviduct, an arrangement which has also been noticed in a couple of lizards. In the Teleostean *Anableps* the yolk-sac has villi which protrude into a dilated ovarian chamber and absorb nutritive material. As to fertilisation, the usual process is that the male deposits the spermatozoa or the milt upon the laid eggs or spawn, but it is evident that fertilisation must be internal when the forms are viviparous or when the eggs are enveloped in a firm sheath.

As an interesting illustration of inter-relations, we may note that the young of the bitterling (*Rhodeus amarus*) live for a time within the gill-cavities of fresh-water mussels—which has its striking counterpart in the fact that the larvæ of the fresh-water mussel are temporarily parasitic on fresh-water fishes like stickleback and minnow.

Parental Care is but rarely exhibited by fishes, and then usually on the part of the males. Love for offspring usually varies inversely with their number, and those of fishes are legion; nor would young fish benefit much by any care, except an impossible providence which would prevent their being swallowed. Apart from numerous viviparous forms, the female of a Silurid genus (*Aspredo*) carries the ova on her belly till they are hatched, just as the Surinam toad bears her progeny on her back; and in *Solenostoma* a pouch for the eggs is formed by the ventral fins and skin. The male stickleback (*Gasterosteus*) makes a nest of grass-stems and water weeds, weaves it round with

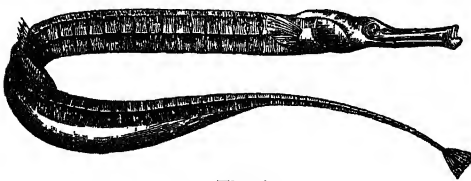

Fig. 4.

The male of a Pipe-fish (*Syngnathus acus*), with pouch beneath the tail for carrying the eggs (after Günther)

mucons threads (which seem to be almost pathological products of the kidneys compressed by the enlarged male organs), and jealously guards the eggs laid by his mate. The same is said to be true of a species of *Chromis* from the Sea of Galilee; and more or less elaborate nests are formed by the males in the genera *Cottus*, *Cyclopterus*, *Antennarius*, *Ophiocephalus*, and *Callichthys*. 'The male of some species of *Arius* carries the ova, about with him in his capacious pharynx,' while in the pipe-

fishes and sea-horses various abdominal brood pouches are developed.

Development.—The fish egg is a small thing, except in the cartilaginous fishes, where it is very large, and enclosed in the characteristic keratin case. In other fishes there are only the usual egg-sheaths, such as the *zona radiata*, with one aperture or more for the entrance of the spermatozoon. Fertilisation usually takes place in the water, much less frequently within the female. Since the old experiments of Jacobi (1757-63), artificial mingling of the sperms and eggs has often been resorted to, both in the embryological laboratory and in the practical work of stocking rivers (see **PISCICULTURE**). In the egg the yolk usually bears a large proportion to the strictly formative material, and the division with which development begins is partial in all known cases except the sturgeon and the bony pike. Development is, in most cases, a

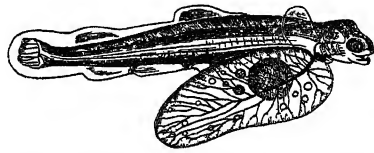

Fig. 5.—Young bony Fish, with dependent yolk-sac still unabsorbed.

rapid process, and the newly hatched forms bear the still incompletely absorbed yolk-sac dependent from their ventral surface. The larval forms are often unlike the parents, for instance, in the possession of external gill-filaments in Elasmobranchs, &c., or in minor features connected with mouth, fins, and armature. The most striking change is that which happens to young, bony Flat-fish (q.v.). See **EMBRYOLOGY**, and such articles as **SALMON**.

Relation to Environment.—In many fishes the limit of growth is less definite and less rapidly attained than is usual among higher vertebrates. In favourable circumstances individuals will go on growing, and may far outstrip the average of the species, while, on the other hand, a confined habitat and restricted food-supply may reduce the size. 'The young of coast-fishes, when driven out to sea, where they find a much smaller supply of food, remain in an undeveloped condition, assuming a hydropic appearance.' Besides affecting the size, the nature of the surroundings and the nutritive supply influence both form and colour. It is a well-known fact that the same species of trout presents a variable appearance, according to the habitat of the individual. It rarely happens among fishes that the pigment wholly disappears, but it is not uncommon for an 'incipient albinism' to be produced by a change of the contents of the pigment-cells into yellow, a variation most familiar in the gold-fish, but occurring in not a few. Very different, and of more importance in the life of the fish, is the power which some possess of sympathetic change of colour. Thus, in the plaice the colour of the environment influences the eye, a nervous impulse determining the contraction or expansion of the pigment-cells passes to the skin, and the animal is adapted to the colour of the ground on which it rests. Few general statements can be made as to the sensitiveness of fishes to changes in the medium. Pelagic fish are very susceptible; but other marine forms—e.g. flounders—thrive well in fresh water. 'A shark lives in Lake Nicaragua; a goby, blenny, and *Atherina* in the lakes of north Italy.' The passage of a fresh-water fish to the sea is very rare. Many fishes can endure prolonged fasting and also lowered temperature,

but in both these respects marine forms are far excelled by those inhabiting fresh water. Low temperature causes some fishes to pass into a torpid state of 'Latent Life' (q.v.), or Hibernation (q.v.), while in the dry season of tropical countries other forms (e.g. Siluroids and Protopterus) encyst themselves in the mud, where they may remain like living mummies for prolonged periods. See also BLIND FISH.

Some small fishes live in amicable partnership with other animals—e.g. inside large sea-anemones (see COMMENSALISM). The genus *Fierasfer* seems in a fair way to become parasitic, since the members find more or less permanent lodging within

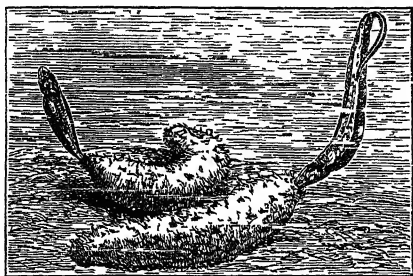

Fig 6.—*Fierasfers* entering and leaving *Holothurians*.
(From the atlas of the Naples Aquarium.)

sea-cucumbers, medusæ, and other animals, feeding, however, not upon their hosts, but upon the minute animals which they contain. Fishes themselves are infested by numerous internal and external parasites. Crustaceans, or Fish-lice (q.v.), occur in great abundance on skin and gills, especially on sluggish or on sickly forms. Various flukes are also found externally, and a large number of Cestodes in tapeworm or bladderworm stages live in the viscera. The pike and burbot are hosts of the immature stages of the formidable *Bothriocephalus*; the stickleback often bears the young of the fresh-water mussel; a peculiar hydroid (*Polypodium*) is parasitic on the eggs of the sturgeon; and so on through a long series (see PARASITIC ANIMALS).

Distribution in Space.—Most fishes live either exclusively in the sea or exclusively in fresh water, but some pass for spawning purposes from the one to the other, and not a few thrive with apparent indifference in either or in a brackish medium. The marine forms enjoy a wider distribution over the globe, but the inhabitants of fresh water also spread by circuitous swimming, by changes in the river systems, and even by short overland marches, or by having their ova carried on the feet of water-birds. Both marine and fresh-water forms occur in Polar regions. Günther describes about forty species from the icy waters at or beyond the 1500 fathom line; and fishes are still present in Alpine lakes about the level of perpetual snow, up, indeed, to a level of 15,000 feet or more. Of genuine fresh-water fishes about 2300 species are recorded, of which four are Dipnoi, thirty-two Ganoids, and the rest Teleosteans, with a marked predominance of carps or Cyprinidae, and Siluroids or cat-fishes. The marine forms are usually distinguished as shore, pelagic, and deep-sea fishes. The shore fishes, including about 3500 species, frequent the coasts, and rarely descend below 300 fathoms. The pelagic fishes swim and usually spawn in the open sea, are less numerous than the shore forms, and thrive especially in the equatorial waters: the cartilaginous fishes form a large percentage of the pelagic fauna. The deep-sea fishes include over a hundred genera, most of which are Teleosteans. Of these

forms, monographed by Günther in his *Challenger* Report, a little more must be said.

Deep-sea Fishes were not known with any definiteness till the *Challenger* expedition virtually discovered the new zoological world which they inhabit. The explorations of the *Talisman* and the *Travailleur* have also contributed important results to our knowledge of these usually strange-looking forms. To understand their peculiarities it is necessary to recall the principal factors in their environment. (a) Sunlight is absent, and so often are eyes, which, in the absence of stimulus, remain undeveloped. It is interesting to notice Günther's results. From a depth of from 80 to 200 fathoms the eyes are larger than usual, to make the most of the scanty sun-rays which fade away at those depths. Beyond the 200 fathom line 'small-eyed fishes as well as large-eyed occur, the former having their want of vision compensated for by tentacular organs of touch, whilst the latter have no such accessory organs, and evidently see only by the aid of phosphorescence. In the greatest depths blind fishes occur, with rudimentary eyes, and without special organs of touch.' The Phosphorescence (q.v.) is produced by numerous marine animals and by the fishes themselves. Many of the latter exhibit round, shining, mother-of-pearl-coloured bodies, imbedded in the skin, in part sensory, in part phosphorescent. (b) The temperature of the bottom is low and equable, and a wide range of distribution is thus unimpeded. (c) The pressure is, of course, enormous at those great depths, and, though the fishes feel it as little as we do that of the air, it has doubtless been an

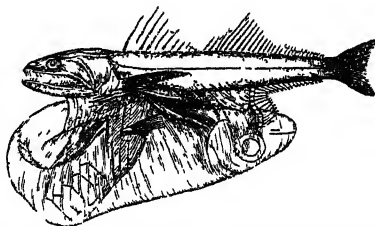

Fig. 7.—A deep-sea fish (*Chiasmodon niger*) which has swallowed another fish (seen beneath) bigger than itself (after Günther).

important factor in determining their structure. Bones and muscles are less developed; the former are very light and brittle; the latter are thin. The forcible ascent to diminished pressure, of course, produces rupture and other changes, so that it is sometimes difficult to infer the natural form of the body and texture of the tissues. (d) As sunlight is absent, so also are plants. The abyssal fish are therefore carnivorous, 'the most voracious feeding frequently on their own offspring, and the toothless kinds being nourished by the animalcules which live on the bottom, or which "like a constant rain" settle down from the upper strata. Some of the carnivorous forms show evidence of great rapacity, and not a few are characterised by wide gape and dilatable stomach, able to 'receive a fish twice or thrice the bulk of the destroyer.' The skin in many deep-sea fishes is marked by an extraordinary development of the mucus-secreting system, and this exuded layer has been observed to be phosphorescent in some fresh specimens. The colouring is simple, most of the forms being either black or silvery. The absence of light and the sluggish habit may have something to do with this peculiarity. (e) Lastly, the perfect calm of the abyssal water must be remembered, and associated with the tendency many of the fishes have to develop long, delicate filaments on fins or tail. As

to the maximum depth at which fishes certainly occur, *Bathypophis ferox* was dredged from 2750 fathoms.

History of Fishes.—The earliest fish remains occur in the Upper Silurian strata, mostly in the form of spines, scales, shields, and mere fragments.

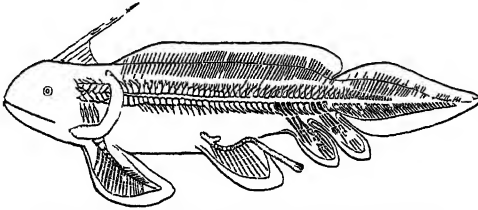

Fig. 8.—Restoration of *Pleuracanthus gaudryi* (Brongniart).

Some of these belong to the archaic order of Hypostomes—e.g. *Pteraspis*—and being without jaws or ordinary paired fins, are probably not fishes in the strict sense. Others are Elasmobranchs of the shark type. In the Devonian and subsequent Palaeozoic periods there were numerous cartilaginous 'Ganoids' and Elasmobranchs and some Dipnoi, besides orders which represent lost races, having no direct descendants to-day. Thus a separate order (Ichthyotomi) must be erected for a form like *Pleuracanthus* which Brongniart discovered in the French coal-measures. Ganoids with a thoroughly ossified skeleton appear first in Jurassic rocks, and about the same time the first Teleosteans (e.g. *Thrissops* and *Leptolepis*) emerged. The bulk of the Dipnoi were Palaeozoic, but *Ceratodus* existed in Triassic and Jurassic times, and has persisted until now. Perhaps the most striking general fact is the decadence of the 'Ganoids' and

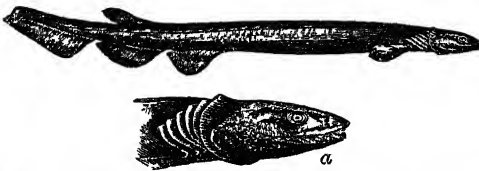

Fig. 9.—*Chlamydoselachus anguineus* (Garman), a frilled shark, one of the oldest living types of Fishes :
a, head on larger scale.

the Dipnoi, while Elasmobranchs have to some extent held their own, and the Teleosteans have become the dominant race of fishes.

Economic Interest.—Apart from the import of fishes in the general economy of nature, their practical interest for mankind is centred in the fact that so many form part of our food-supply. Their importance in this respect is especially great in Polar regions, where other sources of nutrition are scanty. It may be here noticed that many are temporarily or constantly poisonous. The poison is in the blood and is destroyed by heat in the eels; it is constant and in the flesh in *Clupea venenosa*, various globe-fish, and many others; it is temporary and in the roe of spawning pike, burbot, &c.; while in many cases it is not intrinsic, but due to the food on which the fish lives, or to decomposition products formed after death. Gills and other parts which quickly decompose should always be avoided. Some fishes, such as stingrays and weavers, readily give wounds with their spines, and the mucus of the body thus inoculated produces symptoms of poisoning. In Synanceia, *Thalassophryne*, and other forms there are true

poison organs associated with spines, and the results of a wound are sometimes fatal. Besides, the great nutritive utility of fishes, there are a few minor products of some importance, such as cod-liver oil from the liver of Gadoids, isinglass from the swim-bladder of sturgeons, &c., and shagreen from the skin of sharks and rays (see PISCICULTURE).

From their position near the base of the vertebrate series, fishes are the most hopeful subjects for the solution of many of the fundamental problems of zoology; in their endless variety of habit they afford wide scope to the observant naturalist; while for their grace of movement, beauty or quaintness of form, and splendour of colouring they merit a larger share than they have hitherto received of artistic attention.

The whale and the sturgeon, either when thrown on shore or when caught near the coast, are at common law the property of the crown, and as such are known as *Royal Fishes*.

Fishguard, till 1918 one of the Pembroke boroughs, 14½ miles N. of Haverfordwest, has a good harbour, whence since 1906 Great Western Railway steamers run to Rosslare and Waterford in Ireland. Pop. 3000. For the French descent here in 1797, see PEMBROKESHIRE and the *Diary* of D. Rowlands (published in 1892).

Fish-hawk, or FISHING EAGLE. See OSPREY.

Fish-hooks. Both in Europe and in America fish-hooks have been found, belonging to prehistoric times, which are made of flint, bone, shell, copper,

Early Fish-hooks (from Rau's *Prehistoric Fishery*):

a, lacustrine fish-hook, made of a bear's tusk, found at Moosseedorf, Switzerland; b, bronze lacustrine fish-hook, found at Romanshorn, Lake Constance; c, deer-horn fish-hook, found in Madison county, New York; d, shell fish-hook from Santa Cruz Island; e, cactus-spine Indian fish-hook from Arizona; f, halibut hook, made by the Makah Indians, Cape Flattery, from the knots of the hemlock spruce.

bronze, and, on the latter continent, even of gold. The oldest apparatus for catching fish was not a hook, but a cross-bar of flint sharpened at both ends and attached to a thong. Some of the oldest

prehistoric fish-hooks, including a few of bone, bear a considerable resemblance to modern English hooks in shape and in the form of the barb. Many of the rude-looking fish-hooks made by savage races are strong, well made, and ingeniously contrived. The shell and bone hooks of the Maoris of New Zealand and the natives of the Solomon Islands, as well as the bone and iron hooks of the Eskimos, are examples of these. Curious fish-hooks of cactus spines, made by Indians, have been found in Arizona. Ancient Roman fish-hooks discovered at Pompeii exactly resemble those in use at the present day, only they are of bronze instead of steel. But almost as much may be said of the prehistoric bronze fish-hooks discovered in Scotland, Ireland, and at several places on the continent of Europe. Illustrations of a large number of ancient fish hooks are given in a volume on *Prehistoric Fishing in Europe and North America*, by C. Rau, published by the Smithsonian Institution. See also W. Radcliffe, *Fishing from the Earliest Times* (1921).

In England fish-hooks are chiefly manufactured at Redditch in Worcestershire. The best of these are still made by hand, and the following is an outline of the stages in the process. (1) Soft cast-steel wire is cut by shears to the length required for a given size of hook. (2) A number of these cut wires are placed on a plain surface against an upright, and then by means of a strong knife the beads or barbs are formed. (3) The points are next put on by carefully filing the wires, each being pointed almost in an instant. (4) By means of a mould mounted in a wooden handle the wires are bent or turned to the proper shape. (5) The ends of the shanks are now ringed, flattened, or marked by an ingenious machine or hammer. (6) At this stage the hooks are hardened; i.e. they are placed in a furnace and brought to a certain heat, which varies with the kind of hook, and then plunged into a vat of oil. (7) They are next tempered by placing them, mixed with emery sand, in a pot over a charcoal fire. There they are kept in constant motion till they are sufficiently tempered. (8) Scouring is effected by placing the hooks with water in barrels and keeping these in motion for one or two days, to remove all scale. (9) Polishing is done by placing the hooks in an oblong bag with emery and rapidly shaking them. Sometimes the polishing is done in barrels moving round at an angle of 45°. Fish-hooks are now, however, chiefly made by machinery which performs most of the above operations automatically. See ANGLING.

Fishing-frog. See ANGLER.

Fishkill Landing. See BEACON.

Fish-louse, a name widely applied to any of the Copepod crustaceans which occur as external parasites both on fresh-water and marine fishes. Some have also been found on amphibians. As they live on the juices of their hosts, they undoubtedly do damage, and the fishes on which they are abundant are often sickly. They may occur on the skin itself, but are even more common about the gills. To the zoologist they have a special interest on account of the degeneration which they often exhibit, when contrasted with their free-living relatives or even with their own young stages. They are often curiously misshapen, and swollen out with abundant feeding; the males are sometimes free and the females alone parasitic, or the males may be pigmies borne on their mates. In other cases the females become truly parasitic only after sexual union, when about to bear eggs, and the habit of parasitism has doubtless been acquired in some instances for the safety and convenience of the mothers. Some (e.g. *Penella*) pass from being external hangers-on to become true internal para-

sites. The following are examples of common 'fish-lice' and of the hosts which they infest: *Chondracanthus cornutus*, on flat-fish (frequent); *Caligus rapax*, dog-fish, gurnard, lumpsucker, dab, whiting, &c. (frequent); *Ergasilus sieboldii*, carp, pike, &c. (frequent); *Dichelostum sturionis*, sturgeon (on gills); *Lernaeocera cyprinacea*, carp, &c. (boiling in flesh); *Lernaea branchialis*, flounder, &c. (on gills); *Penella sagitta*, fishing-frog (in flesh); *Achtheres percarum*, perch, &c. (on gills); *Lernaeopoda elongata*, dog-fish (on eyes); *Anchorella uncinata*, cod species (on fins and gills); *Argulus foliaceus*, carp, perch, pike, stickleback, trout, &c. (frequent). The above are all Copepods—i.e. low down in the crustacean series; but parasitic Ciliopodes (q.v.) occur in the skin of whales and fishes, and on other crustaceans; a little family of Amphipods (Cyamidae) also infest cetaceans; among Isopods, many Cymothoidae live on the skin and gills of fishes, while Bopyridae and Etoniscidae frequent other crustaceans. See CRUSTACEA, PARASITIC ANIMALS.

Fish-louse (*Achtheres percarum*), magnified.

Fish-skin Disease. See ICHTHYOSIS.

Fiske, JOHN, born 30th March 1842 at Hartford, Conn., studied at Harvard, where in 1869 he began as a positivist to lecture on philosophy, and in 1872-79 was under-librarian. He was widely known as a lecturer. Among his works are *Tobacco and Alcohol* (1868), *Myths and Myth-makers* (1872), *Outlines of Cosmic Philosophy* (2 vols. 1874), *Darwinism* (1879), *The Beginnings of New England* (1889), *Theodore Parker* (1889), *The American Revolution* (1891), *The Discovery of America* (1892), *Old Virginia and her Neighbours* (1897), *Through Nature to God* (1899), *A Century of Science* (1900). He died 4th July 1901. See his *Life and Letters* by J. S. Clark (1920).

Fissirostres, Cuvier's name for wide-gaping, insect-eating goatsuckers, swifts, and swallows.

Fistula, an abscess contracted to a narrow, hard, open passage in communication with, or in the immediate neighbourhood of, one of the mucous canals, lined by a kind of false membrane, giving rise to a thin discharge. There is salivary fistula, urinary fistula, &c.; but the most common and troublesome kind of all is the *fistula in ano*, in the lower bowel (see ANUS, RECTUM). The term is also applied to unnatural communications between two adjacent mucous canals (e.g. vesico-vaginal fistula), or between one of these and the external surface (e.g. gastric fistula, fœcal fistula), independently of their size and shape. The treatment of fistula should only be entrusted to experienced surgeons.

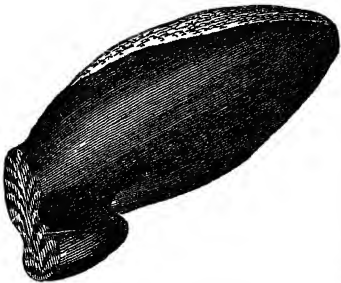

For the cure of salivary or urinary fistula all that is generally necessary is to restore the patency of the natural ducts, which is done by passing instruments along them. Should a fistula, however, be situated where it is surrounded by muscular fibres, as at the orifice of the lower bowel, it is necessary to divide these, so as to leave the part at rest while nature repairs it. During the process of healing care must be taken that the wound closes from the bottom, otherwise the cut surfaces are apt to reunite, leaving the fistula unimproved. This may be secured either by stuffing the wound with lint, or by daily passing a probe or a finger along it to break down any adhesions that may have formed. Stimulant applications are also

sometimes necessary to promote the healing process.

At times, however, fistulæ require more elaborate treatment, and are extremely difficult to close, especially those which result from loss of tissue between two adjacent mucous canals; fortunately, however, modern surgery is able to remedy these also. It is necessary to make the edges of the orifice once more raw, and to bring them in contact, but formerly the wound used rarely to unite, as the stitches produced such an amount of irritation. Now, however, by the use of silver-wire, or catgut, and by scrupulous attention to cleanliness, the parts can be kept together long enough to insure union; and thus, by the ingenuity of American surgeons, especially the late Marion Sims of New York, and others in Britain, certain diseases of women, arising from protracted labours, and formerly rendering the unfortunate subjects of them miserable and unfitted for any of the duties of life, may be now remedied by a skilfully performed operation.

Fistularia, Fistularidæ. See FLUTE MOUTHS.

Fistulina, a genus of Hymenomycete fungi allied to *Boletus* (q.v.), family *Polyporei*; the under surface (*hymenium*) at first covered with minute warts, which ultimately form separate tubes. *F. hepatica* is common in Britain and throughout Europe on old oak, walnut, and chestnut trees; it occurs also on ash and beech. It is semicircular, of very regular outline, with a lateral stem, or none; its colour red; its substance fibrous and fleshy, much resembling beet-root. When old and beginning to decay, it looks like a mass of liver. It sometimes attains a great size. Mr Berkeley mentions one which grew on an

Fistulina hepatica.

ash pollard, and weighed nearly thirty pounds. This fungus, while young, is much esteemed in some parts of Europe as an esculent; whilst there is almost no possibility of confounding it with any dangerous fungus. Its taste resembles that of the common mushroom, but is rather more acid. 'When grilled, it is scarcely to be distinguished from broiled meat.' It furnishes itself with abundance of sauce.

Fitch, JOHN, inventor, was born in what is now South Windsor, Connecticut, in 1743, and after a short, unhappy, married life, and a period of wandering, settled at Trenton, New Jersey. At the outbreak of the revolution he became a gunsmith for the American troops, with whom he wintered at Valley Forge. He next made surveying and trading tours in the West, and after escaping from captivity among the Indians returned to Pennsylvania, where in 1785 he completed his first model of a steamboat; this had wheels at the sides, which were replaced in the following year with paddles or oars. In the face of discouragement and neglect he succeeded in constructing a vessel, 45 feet long and 12 feet beam, with an engine of 12-inch cylinder, which made a successful trial-trip on the Delaware, at Philadelphia, 22d August 1787. Larger vessels were built in 1788 and 1790, the latter being run as a passenger-boat, at eight miles an hour, to Bur-

lington (20 miles) throughout the summer. Misfortune, however, dogged 'poor John Fitch's' steps; his supporters fell away; and in 1793 he went to France to construct a steamboat, only to find his project frustrated by the Revolution there. It is said that his plans and specifications were deposited with the American consul at L'Orient, who for several months entrusted them to Robert Fulton (q.v.); and the latter's steamboat certainly was in 1817 declared by a committee of the New York legislature to be 'in substance the invention patented by John Fitch in 1791.' Penniless and dejected, Fitch worked his passage back to America, where in the summer of 1798 he is said to have committed suicide in a tavern at Bardstown, Kentucky.

Fitchburg, a city of Massachusetts, on the Nashua River, at the junction of three railroads, 40 miles WNW. of Boston. It has granite quarries, and manufactures of rolling-stock, machinery, paper, shoes, and tools, besides iron-foundries. Pop. 41,000.

Fitches. See VETCHES.

Fitchet. See POLE-CAT.

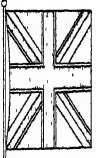

Fits, sudden seizures of disease implying loss of consciousness, or any considerable change in the condition of the mind, but particularly attacks of Epilepsy (q.v.), and other forms of Convulsions (q.v.).

Fitz (also *fix* and *filtz*) is an old Norman-French word signifying 'son,' from the Lat. *filius* (Fr. *fils*). Like the Gaelic *Mac*, the Irish *O'*, and the oriental *Ben*, it is prefixed to proper names to signify descent, as in the Norman names Fitzwilliam, Fitzwalter, Fitzgerald. A special application of it is for natural sons of royalty, as in Fitzroy, Fitzjames (see BERWICK, DUKE OF), and Fitzclarence.

Fitzgerald, LORD EDWARD, a prominent member of the society of United Irishmen, was a younger son of the Duke of Leinster, and was born at Carton Castle, near Dublin, October 15, 1763. After his father's death he was brought up in France, but returned to England in 1779 to enter the army. He served with distinction in the American war, next sat for Athy in the Irish parliament, and was drawn to Paris by the resistless spell of the great Revolution. Here he renounced his nobility, and married Pamela (long believed to be a daughter of Madame de Genlis by *Egalité* Orleans; really a daughter of G. de Bixey and Mary Sims, born in Newfoundland). Returning to Ireland in 1793, he joined the United Irishmen in 1796, and went to France to arrange for a French invasion of Ireland. Soon after his return the plot was betrayed to the government, and Fitzgerald, after a few days of hiding in Dublin, was seized, not without a desperate scuffle, in which he received wounds of which he died, sixteen days later, 4th June 1798. See the Lives by Moore (2 vols. 1831), Taylor (1903), and Campbell (1904).

FitzGerald, EDWARD, was born March 31, 1809, at Bredfield House, near Woodbridge, in Suffolk. His father, John Purcell, took his wife's family name on her father's death in 1818. In 1816 the family went to France, and lived for a time at St Germain, and afterwards at Paris. In 1821 he was sent to King Edward VI.'s School at Bury St Edmunds, where James Spedding, W. B. Donne, and J. M. Kemble were among his schoolfellows. He went up to Trinity College, Cambridge, in October 1826, where Spedding joined him the next year, and where he formed fast friendships with Thackeray, W. H. Thompson, afterwards Master of Trinity, and John Allen, afterwards Archdeacon of Salop. He took his degree in January 1830.

His father's family resided at Wherstead Lodge, near Ipswich, from 1825 to 1835, and subsequently at Boulge Hall, near Woodbridge; there he lived with them until 1838, when he took up his separate residence in a cottage near the gate of Boulge Hall. His life at this time was a quiet round of reading and gardening, occasionally broken by visits from or to friends; his chief friends in the neighbourhood were the Rev. G. Crabbe, the son of the poet, and vicar of Bredfield, Archdeacon Groomer, and Bernard Barton, the Quaker-poet of Woodbridge, whose daughter he afterwards married. Every spring he used to make a long visit to London to see his friends. There he constantly met Donne, Spedding, and Thackeray, and was a frequent visitor at Carlyle's house. Lord Tennyson and his brother Frederic had been his contemporaries at college; but it was in London that they became intimate; how fast the friendship was is best shown by Lord Tennyson's dedication of *Tiresias*. In 1853 he left the cottage and settled near Woodbridge, and afterwards in the town itself; but in 1874 he removed to Little Grange, a house which he had built for himself in the neighbourhood. His great outdoor amusement in these years was yachting; and every summer was spent cruising about the Suffolk coast, especially near Lowestoft and Aldborough, the latter locality being of great interest to him as associated with the poems of his favourite, Crabbe. He thoroughly enjoyed the life on his yacht, carrying his books with him, and delighting to take his friends for short trips, when they might read and talk over well-known passages together. He also enjoyed the rough, honest ways of the sailors and fishermen; and he liked to collect their peculiar words and phrases. But he could not escape 'the browner shade' which Gibbon ascribes to the evening of life, and the sea gradually lost its charm; one old sailor died, and another grievously disappointed him; and he at last gave up the yacht for his garden, where his favourite walk was called the 'Quarter-deck.' He died suddenly, June 14, 1883, while paying his annual visit to his friend the Rev. G. Crabbe, the poet's grandson, at Merton Rectory, Norfolk. One of his great characteristics was steadfastness in friendship; he was slow to form intimacies, but, once riveted, the link lasted till death. His outward manner was reserved, and he might sometimes seem a little wayward or petulant; but under all this cold exterior there lay a tenderness like Johnson's, and a fine stroke of imagination or a noble deed would make his voice falter and his eyes fill with tears.

The first forty-two years of his life passed in quiet reading and thinking, and it was not till 1851 that he published anonymously his dialogue on youth, *Euphranor*, which was followed by *Polonius* in 1852. In the meantime a friend had persuaded him to begin Spanish, and this not only opened a new world of interest, but revealed to him his own powers. He at once took to Calderon's plays, and afterwards to *Don Quixote*, and in 1853 he published a translation of six dramas of the former with his name attached; but he soon withdrew it from circulation, and two more were afterwards printed privately. About 1853 the same friend interested him in Persian. Sa'di's *Gulistan* early attracted him by its quaint stories, and in 1856 he published an anonymous version of Jami's *Salman and Absal*; and he also wrote, but never printed, an abridgment in verse of Attar's *Mantik ut tair*. But the Persian poet who most interested him, from the time of his first seeing his works in 1856 in a MS. in the Bodleian Library, was Omar Khayyam, the astronomer-poet of the 11th century. These poems were then known only by a few current quotations, as they were first printed at

Paris in 1857 by M. Nicolas; but FitzGerald at once recognised their beauty, and his name and the poet's will probably remain indissolubly linked together. Here his genius as a translator appears at its height. He possessed to an extraordinary degree the power of reproducing on his reader the effect of the original; and, though the original ideas are often altered, condensed, and transposed in an apparently reckless way, these lawless alterations are like Dryden's, and they all tell.

See his letters, his works, and his *Letters to Fanny Kemble*, ed. Aldis Wright (7 vols. 1889-1901 and 1902-3); a *variorum Omar*, ed. F. H. Evans (1915); *Life* by T. Wright (1904); monograph by A. C. Benson (1905).

Fitzherbert, MRS., a Roman Catholic lady, born Maria Anne Smythe in 1756, to whom, after she had been a second time left a widow, the Prince of Wales, afterwards George IV., was secretly married in 1785 by an Anglican clergyman. This marriage, contracted without the king's consent, was of course invalidate under the Royal Marriage Act of 1772; but the prince carried his meanness so far as to persuade Fox to deny that there had been a marriage at all, and afterwards denied that he had done so. On his marriage to the Princess Caroline in 1795 the connection was broken off for a time, to be resumed with the pope's consent, and finally broken off in 1803. Mrs Fitzherbert, whose conduct in trying circumstances has been warmly praised, died at Brighton, 29th March 1837. See her *Memoirs* by Langdale (1856), and a *Life* by Wilkins (1905).

Fitzroy, the largest river of Western Australia, has its sources in the King Leopold Range, and, after describing a wide curve to the south, reaches the sea at the southern end of King Sound after a course of 300 miles, the lower 100 navigable for small boats. It was discovered by Stokes in 1833.—For the Queensland Fitzroy, see ROCK-HAMPTON. Fitzroy is also the name of a north-eastern suburb of Melbourne.

Fitzroy, ROBERT, admiral and meteorologist, a grandson of the third Duke of Grafton, was born at Ampton Hall, near Bury St Edmunds, July 5, 1805, and entered the navy in 1819. His first important work was that of surveying the coasts of Patagonia and Tierra del Fuego, 1828-30; and this work he was charged to continue on his reappointment to the command of the *Beagle* in 1831. On this voyage he was accompanied by Darwin, the two together publishing in 1839, three years after their return to England, a *Narrative of the Surveying Voyages of H.M.S. 'Adventure' and 'Beagle'*, vols. i. and ii. by Fitzroy, and vol. iii. by Darwin. For two years (1843-45) he was governor of New Zealand, then a newly-constituted colony. Although placed on half-pay in 1850, he was promoted in due course to be rear-admiral (1857) and vice-admiral (1863) on the retired lists. In 1854 he received an appointment in the meteorological department of the Board of Trade, his attention being principally given in his later years to meteorology and the lifeboat service. The cheap and serviceable 'Fitzroy barometer' was made on a plan suggested by him; and it was he who instituted the system of storm warnings that has grown into the daily weather forecasts. Among his works are *Meteorological Observations* (1859), and *Weather-book* (1863), as well as *Remarks on New Zealand* (1846). He put an end to his own life, in a fit of mental aberration, 30th April 1865, at Norwood in Surrey.

Fitzwilliam, WILLIAM, Earl Fitzwilliam, was born in 1748, and, succeeding his father in 1756, took his seat in the House of Lords in 1769. He at first opposed Pitt, to whom he afterwards went over, with a considerable portion of the Whig party, owing

to the excesses of the French Revolution. As lieutenant for three months of Ireland (1794-95), where his warm support of Catholic emancipation aroused enthusiastic hopes, he was considered by Pitt too liberal; and his recall was followed by the rebellion of 1798. He was president of the council in the Grenville ministry, in 1806, and took some part in the Reform Bill agitation. He died 8th February 1833.

Fiume (Serb. *Rjeka*, Lat. *Fanum Sancti Viti ad flumen*), an important seaport and district, at the mouth of the Fiumara or Rjeka, 142 miles WSW. of Zagreb by rail, and 35 miles ESE. of Trieste across the Istrian peninsula, stands at the head of the beautiful Gulf of Quarnero, in the Adriatic, where the Julian Alps end. It consists of an old and a new town, the latter on the sea, being well built and laid out with many handsome streets and squares. Its extensive industries include oil and rice refineries; shipbuilding; starch, tobacco, chocolate, paper, and macaroni factories; chemical works, and tanneries. The tunny-fisheries of the Gulf also are valuable. Fiume's chief importance, however, is as a great entrepôt of commerce, the place being the sole practicable maritime outlet for the produce of the whole middle-Danubian basin. A free port from 1717 till 1891, it has a harbour with a lighthouse and several breakwaters, which was greatly improved by the Hungarian government in the years following 1872, when new moles and quays with warehouses, and petroleum and other docks, were added at a cost of nearly a million sterling, with the immediate effect of increasing the trade fivefold within the next twelve years. Further improvements were begun in 1888 and in 1902. The exports are chiefly flour and grain, sugar, oak staves and timber, wine, mineral waters, magnesite, tannin, and tobacco; the imports, cereals, textile raw materials, and leaf-tobacco. The trade is almost entirely a transit trade, even the petroleum and rice going forward into the interior after manipulation. The chief imports from Britain are cotton goods and yarn, American tobacco, machinery, hardware, and coal; a large quantity of paddy rice and jute are imported from British India. Population (with Sushak, its eastern Slav suburb), 60,000, including Italians and Southern Slavs in about equal numbers. Both nations hoped to obtain Fiume (then a free town under the crown of St Stephen) as a part of the spoils of the Great War. Long and troublesome negotiations ensued, and were broken in upon by Gabriele D'Annunzio (q.v.), who, with a band of volunteers, seized the town on the 12th September 1919. The treaty of Rapallo (November 1920) made Fiume an independent state (8 sq. miles; pop. 65,000). It was agreed in 1924 that the city should be Italian, Sushak and part of the harbour Yugoslav.—The county of Fiume, in Croatia, between Carniola and the sea, is almost entirely filled by the Karst range. In the relatively small valley area, and along the coast, olives, figs, pomegranates, and citrons flourish.

Five Members, THE, were those members of parliament—John Pym, John Hampden, Denzil Holles, Sir Arthur Haselrig, and William Strode—whom Charles I. endeavoured to arrest on 4th January 1642. This action, by which Charles had meant to prevent the impeachment of the queen, precipitated the Civil War. See CHARLES I.

Five-mile Act, an Act passed in 1665, enacting that no Nonconforming clergyman should be allowed to come within five miles of a corporate town, or of any place where he had once ministered, nor act as a tutor or schoolmaster, unless he first took the oath of non-resistance, and expressed his willingness to make no attempt to alter the constitution of either church or state.

Fives, a game of hand-ball still popular in England, chiefly at the great public schools. The game existed at least as early as the 14th century, both in France and England, being termed 'palm-play' in the former, and 'hand-tennis' in the latter; its name is derived from its being played with the 'bunch of fives'—i.e. hand. The principle of the game is very simple, although the minor rules depend largely on local tradition. In a 'single' one player constitutes a side; in a 'double' there are two on either side. A roomy court is requisite, bounded by a high wall at one end, and against this wall a ball is propelled by striking it with the open hand. A 'close' court has also two side walls, and the whole is sometimes covered. The game is begun by one player striking the ball against the wall, and causing it to rebound anywhere beyond the floor-score, which is about two yards from the wall; the ball as it rebounds is then returned by the opposing sides alternately, a player's stroke counting a failure whenever the ball does not touch the wall higher than three feet from the ground, and the opposite side scoring one. The ball may be struck either from a direct rebound before it reaches the ground, or after it has 'dapped' or hopped from the ground once. Fifteen is usually game. When the players are skilful the ball is kept going by the alternate strikers for many minutes at a time, and the game is thus rendered exciting both for players and onlookers.

Fixed Bodies is a term applied in chemistry to those substances which remain fixed, and are not volatilised at moderately high temperatures.—*Fixed Air* was the name given in 1756 by Dr Joseph Black (q.v.) to what in 1784 was named by Lavoisier Carbonic Acid.—*Fixed Oils* are those oils which, on the application of heat, do not volatilise without decomposition. See OILS.

Fixed Stars. See STARS.

Fixtures, THE LAW OF, is very much the same in England and Scotland. The general idea of a fixture is that a movable has been fastened to the soil or to a house, and has thus become the property of the owner of the soil or house. Such questions arise frequently between vendor and purchaser, heritable and ordinary creditors, heir and executor, landlord and tenant. The last case is that most favourable for the right to remove a fixture. The first question is, however, whether the movable has become a fixture. Things not actually attached may be constructive fixtures—e.g. the keys of doors, the leathern belts of machinery, &c. In general, however, there must be physical annexation. Apart from this the main tests are: (1) can the thing be taken away without material injury to itself or to the premises? (2) is it essential, or material, or specially adapted to the enjoyment of the premises? In a famous case salt pans were held to be fixtures, because, though they could be removed without much injury, they were necessary to the use of the premises. But, further, especially between landlord and tenant, it is important to know what was the purpose of annexation, the intention of parties; were the things intended for perpetual or for temporary use? In *non-agricultural* subjects there are two main classes of fixtures—viz. those put up for ornament, convenience, or domestic use, and those put up for purposes of trade. The removability of the first class is a good deal settled by custom. The character of the article may show it to be purely temporary, otherwise the test must be whether the injury of detachment would be substantial. In dwelling-houses, for instance, pier-glasses, ornamental chimney-pieces, grates, book-cases screwed to the wall, are all regarded as movables, and

therefore removable by the tenant. Of course, injury caused to the premises by removal must be repaired by the tenant. In trade, on the other hand, all trade appliances and machinery put in by a tenant for the purposes of his trade are removable by the tenant, if there is no custom or stipulation to the contrary. Questions as to the right to remove fixtures are frequently settled by a remit to a practical man acquainted with the practice of the particular trade. In England a tenant cannot, unless by permission, remove fixtures *after* quitting the premises at the end of his lease. As regards *agricultural* subjects, the law in both England and Scotland is now largely statutory. The English and Scottish Agricultural Holdings Acts of 1883 placed the agricultural tenant (which includes pastoral, market-garden, and mixed holdings) in almost as good a position as the commercial tenant. To some extent this had been accomplished for England by a previous act in 1851. Prior to these statutes everything physically annexed by the tenant became the property of the landlord without compensation. The general statutory rule under the Agricultural Holdings Acts of 1908 now is that where a tenant puts up any engines, machinery, fencing, or other fixtures and buildings for which he is *not* entitled to compensation under the statutes, he is entitled to remove them if he has given a month's notice, and has paid his rent. The landlord, however, by counter notice, may purchase the fixture at a valuation. The tenant has to make good any damage occasioned to the holding by the removal.

Flabellum (Lat.). See FAN.

Flaccus. See HORACE, FESTUS, and PERSIUS.

Flaccus, C. VALERIUS, a Roman poet, who flourished in the time of Vespasian, but of whose life nothing is known. He wrote the *Argonautica*, an unfinished epic poem, a good example of learned mediocrity rather than of genuine inspiration. The chief editions are those of Thilo (1863) and C. Schenkl (1871). An English metrical translation was published by Nicholas Whyte in 1605. See a *Study* by Summers (1894).

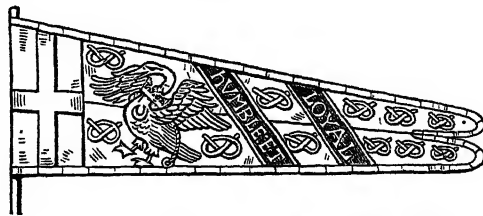

Flacius, or VLACICH, MATTHIAS, surnamed Illyricus, a pupil of Luther and Melancthon, was born at Albona, in Illyria, in 1520. He studied at Basel, Tübingen, and Wittenberg successively, and became professor of the Hebrew Scriptures at this last-named university in 1544. From this time he took an active part in all the theological discussions of the time; and for his attacks upon Melancthon's compromise, known as the Leipzig Interim, he was, four years later, deprived of his professorship. Nor did he procure another appointment until 1557, when he became professor of Theology at Jena. This post he again lost, after holding it for five years, on account of his doctrine that original sin was essentially inherent in man's nature. After this he led a wandering life, dying in great poverty at Frankfurt-on-Main in 1575. Of his numerous works three deserve mention—*Clavis Scripture Sacre* (1567), *Catalogus Testium Veritatis* (1556), and *Ecclesiastica Historia* (1559–74). It is said that Flacius, in order to gather materials for his work, visited, in the disguise of a Franciscan monk, several monastic libraries throughout Europe, and purloined from them such MSS. as were useful to him, amongst those thus stolen being the original of Fordun's *Scotichronicon*, which, with other MSS., was after his death purchased by the Duke of Brunswick for the library at Wolfenbüttel. The history, called *Magdeburg Centuries*, was only partly written by him. See CHURCH HISTORY, and Preger's monograph (1861).

Flag, a popular name for many monocotyledonous plants with sword-shaped leaves, mostly

growing in moist situations. It is sometimes particularly appropriated to the species of Iris (q.v.) or Flower-de-luce, especially to the common yellow flag (*I. pseudacorus*); but is given also very indiscriminately to other plants of similar foliage, as the *Acorus Calamus* (see CALAMUS), which is called Sweet Flag. It is even frequently applied in the United States to some of the algae—e.g. *Fucus* (q.v.).

Flag, a piece of some coloured fabric (usually bunting), generally with a design upon it, and attached by an edge to a staff or halyard, used as a national or personal emblem for military and naval purposes, for signalling, or for decoration or display. As a military ensign, it was probably developed out of the fixed standard of the Romans and other ancient nations through the *vexillum* and *labarum* . With the use of the feudal system the use of flags became more and more common, and by the 11th century they were in general use by military leaders, as may be seen from the Bayeux Tapestry. Flags may be divided into four classes—the standard, the banner, the pennon, and the gonfalon.

The *Standard*, as its name implies, was not meant to be carried about, but to be fixed on the ground either as a rallying-point or to show the location of its owner. Standards are not now generally used, but they were much in evidence in medieval times. They were of enormous size, ranging from eight yards in length for a king, down to four for an ordinary knight. The standard never bore the full arms of its owner; next the staff, or, as it is technically termed, at the 'hoist' of the standard, was depicted the Cross of St George in England or that of St Andrew in Scotland; the end or 'fly' of the standard was rounded off and split into two. On the flag itself two bands were drawn obliquely across it containing the motto of the owner, while in the vacant spaces on each side of the bands were his badge, crest, or small charges taken from his

Standard of Sir Henry de Stafford, K.G., 1475.

shield-of-arms. The colours of the standard were generally regulated by the 'livery colours' of the possessor—that is, the principal metal and tincture which appeared on his arms. The accompanying illustration gives a good idea of a 15th century standard; the badge here displayed so frequently is that termed the Stafford Knot (see BADGE). The *pennant* or *pendant* is a miniature standard in shape, usually much elongated, but is not charged with any device except a cross at the hoist. It is practically only used at sea, and the pennant of a battleship may be some 6 inches in breadth by 20 yards long.

The *Banner* (q.v.) is rectangular in form and ought to be exactly square. On it are depicted the arms of its owner, taking up the entire surface of the flag without any shield or external ornaments being displayed. The *Siege of Caerlaverock*, a Norman-French rhymed chronicle of the 14th century, describes the arms on the banners of all the lords and knights-banneret who were with Edward I. on his campaign against Scotland in 1300. The flag flown by the king, usually called the royal

standard, should really be styled the royal banner. It contains the personal arms of the sovereign, and should never be displayed except where he is actually present; it is a popular error to suppose that this flag is in any way national.

The *Pennon* was a smaller flag carried below the lance-head, and tapered or forked at the extremity. It was, from its size and shape, the most easily carried of all flags; but it was not every one who could use even a pennon—it could only be borne by a knight who had followers to defend it. It generally bore, in heraldic times, the arms or badge of its owner, which were so displayed as to appear correct when the lance was at the rest, not when held upright. A diminutive of the pennon was the pennoncel, a flag that might be borne by esquires, but which was chiefly used in large numbers at funerals, when heraldic displays were one of the chief features at such functions.

The *Gonfalon* or *Gonfalon* (*Scotticé*, gumphoon) was a very early shape of flag, said to have been originally fixed in a frame in which it could turn; later, however, it came to be suspended from one end to a cross-bar from which it hung downwards. It was and is the most usual form for religious and ceremonial flags, and was also largely used, like the pennoncel, at funerals. Sometimes an immense number of them were painted with the arms of the deceased; they were quite small, and must have been rather roughly done, as they were turned out by the dozen.

An account of military flags is given under COLOURS (MILITARY). What follows relates chiefly to national flags as borne at the present time or lately. Their most general and important use is at sea, as ships sail under the colours of the country in which they are registered; but national flags are, of course, frequently displayed on shore also.

The union flag of the United Kingdom, or Union-jack, as it is often incorrectly termed (a jack being a miniature flag displayed from a staff at the end of the bowsprit), took its origin, in 1606, soon after the union of the crowns of England and Scotland. As it was desirable to have a common flag for the two kingdoms, a combination was made of the red St George's Cross of England and the white St Andrew's Cross of Scotland, retaining the blue ground of the latter and superimposing the Cross of St George over that of St Andrew. But in making this arrangement it was necessary, from a heraldic point of view (which forbids colour to be put on colour), to place a narrow border (technically called a fimbriation) of white on the outside of the red cross, so as to separate it from the blue ground. Such was the first union flag. In 1801, at the union of Ireland, the red saltire of St Patrick had to be united with the former two crosses in the union flag. The way that was done was as follows: The white St Andrew saltire was halved in breadth, and a corresponding breadth of the St Patrick red saltire was laid alongside it, but on the reverse side, in each quarter, or in heraldic language counter-changed. But this, again, involved colour being placed on colour, so, in accordance with the above-mentioned rule, a narrow fimbriation of white was put in between the red saltire and the blue ground. It should be borne in mind, also, that a line running down the centre of the united saltires of St Andrew and St Patrick (irrespective of the fimbriation at the side of the latter) should pass through the true centre of the flag, though, of course, it is discontinued when meeting with the Cross of St George. The following is the official blazon of the flag: 'Azure the crosses saltires of St Andrew and St Patrick quarterly per saltire, counterchanged argent and gules, the latter fimbriated of the second, surmounted by the Cross of St George of the third, fimbriated as the saltire.'

The blazon assumes that the two saltires are to be of the same width, but the official proportions given for making the flag involve reducing the width of the St Patrick saltire, so that it and its narrow fimbriation must together be equal to the broad white of the St Andrew saltire.

The union flag, though not strictly a land flag, may be used on shore by any British subject. This was distinctly stated in 1908 on behalf of the government of the day. Certain official persons, such as military officers commanding stations, honorary diplomatic servants, and governors of colonies, bear the union flag with a distinguishing mark in the centre. At sea the union flag pure and simple is only borne by an admiral of the fleet at the main-top-gallant masthead in place of a pennant. Otherwise the union is combined with one of three ensigns—white, blue, and red—corresponding to the three divisions into which the British fleet was at one time divided. That system was abolished in 1864, but the different ensigns are still in use. The white ensign is charged with the St George's Cross, and in the upper corner next the staff the union flag appears; it is used by all British ships of war and by the Royal Yacht Squadron. The blue ensign, a similar flag, but unchanged with any cross, is flown by the Naval Reserve and certain yacht clubs; while the red ensign is borne by all other vessels belonging to British subjects. The Union-jack, with a white border of one-fifth the size of the jack, is used as a pilot-flag by British ships in all parts of the world.

There are certain personal flags apart from that of the sovereign which may be mentioned here. The Lord High Admiral's flag, or Admiralty flag, is red, with an anchor and cable, and is hoisted when that functionary or any of the Commissioners of the Admiralty are on board. Admirals fly a white flag with the red St George's Cross thereon displayed; vice-admirals the same, with one red ball in the upper canton next the staff; and rear-admirals one red ball in the upper and another in the lower canton, both next the staff. Commodores fly a broad white forked pennant charged with the St George's Cross. The following ensigns are borne by the under-mentioned officers, in a circle:

The Lord Lieutenant of Ireland bore the union, and in the centre a blue shield charged with a gold harp. Diplomatic officers bear the union, and in the centre a white circle charged with the royal achievement, and surrounded with a green garland. Governors of colonies and administrators thereof bear the union, and in the centre a white circle bearing the arms or badge of the colony, and surrounded by a green garland. Officers in the consular service bear, while afloat, the blue ensign with the royal arms in a white circle on the fly thereof—that is, in the centre of that part between the union flag and the end of the flag; but when ashore an imperial crown takes the place of the royal arms. General officers commanding fly, when afloat, the union, and in the centre the royal initials surmounted by a crown all on a blue circle surrounded by a green garland. Lords lieutenants of counties fly the union flag charged with a sword, lying fess-ways, point to the fly, and in the upper member of the St George's Cross the royal crown.

The following is a description of the flags of some of the principal nations of the world:

Argentine Republic.—The ensign is divided laterally into three equal parts, blue, white, and blue. In the centre of the white stripe is a golden sun.

Austria.—The flag of the republic is divided horizontally into three stripes, red, white, and red.

Austria-Hungary.—The emperor's standard was yellow, having within an orle of eight crowns the double-headed eagle of the empire, ensigned with an imperial crown, its wings charged with eleven

small crowned escutcheons, and its breast with one large one bearing the arms of Hapsburg, Austria, and Lorraine, and surrounded by the collar of the Golden Fleece. The standard was enclosed in a border, indented, of gold, red, white, and black. The ensign had three broad horizontal stripes, red, white, and red, the middle one being charged with an escutcheon divided as the flag itself, surrounded by a gold border and surmounted by a crown. The merchant flag was similar, but with an additional escutcheon for Hungary and with the lower stripe divided into two halves, red and green.

Belgium.—The royal standard is divided vertically into three parts, black, yellow, and red, with the royal arms in the centre division. The merchant flag is the same, without the royal arms.

Brazil.—The national flag is green, with a yellow diamond-shaped compartment in the centre bearing a globe of pale blue studded with stars, with the words *Ordem e Progresso* in a white equatorial line.

Chile.—Two horizontal stripes. On a blue canton occupying the third part of the upper stripe nearest the hoist is a white star.

Chinese Republic.—The national flag is divided into five horizontal stripes, red, yellow, blue, white, black (reading from the top of the flag). Merchant vessels fly these colours only. The ensign is red with a blue canton charged with a white sun.

Czechoslovakia.—Two horizontal stripes, white and red, intersected by a blue triangle having its base at the hoist.

Denmark.—The ensign is a bifurcated red flag with a white cross; when used as a standard the royal arms are inserted on a white ground in the centre of the cross.

France.—The ensign is divided vertically into three equal parts, blue, white, and red. The merchant flag is the same.

Germany.—The national flag is divided into three horizontal stripes, black, red, and yellow (reading from the top). The merchant flag has horizontal stripes of black, white, and red, with the national colours in the upper hoist canton. The standard of the emperor was yellow, semée of sable eagles displayed and crowns; in the field was the Iron Cross throughout, its arms charged with the words *Gott mit uns*, 1870. In the centre was the escutcheon of the empire, a gold shield with a black single-headed eagle bearing on its breast an escutcheon with the arms of Hohenzollern. The principal escutcheon was surrounded by the collar of the Order of the Black Eagle. The ensign consisted of a white flag with a plain black cross, the arm on the fly being longer than that on the hoist. The cross was cotised or bordered with a narrow stripe of black at a little distance from the edge; in the centre of the cross was a white circle bearing the German eagle, and the first quarter of the flag was divided into three horizontal parts, black, white, and red, with the Iron Cross over it. This quarter formed the jack, and the merchant flag was similar to the jack, with the exception that the Iron Cross was omitted.

■ *Greece.*—The jack is blue, with a plain white cross throughout. The merchant flag is a curiously designed flag of five horizontal blue and four white stripes, with a white cross on a blue ground in the upper quarter next the hoist.

Italy.—The royal standard is pale blue, with a crown at each of the four corners. In the centre is a black single-headed eagle displayed, ensigned by a crown, and bearing on its breast a red shield with a white cross; the eagle is surrounded by the collar of the Order of the Annunciation. The ensign is divided into three vertical parts, green, white, and red; in the centre compartment is the red shield and white cross of Savoy within a blue

border, and ensigned by a crown. The merchant flag is the same, without the crown.

Japan.—The imperial standard is red, with a gold chrysanthemum in the centre. The ensign is white, with a red ball nearer the hoist than the fly, with sixteen red bands radiating from it and getting broader as they approach the edge of the flag. The jack is white, with a red ball in the centre.

Netherlands.—The royal standard is yellow, with a blue cross charged in the centre with the royal arms surrounded by the orange ribbon and badge of the Order of William I.; in each of the four quarters of the flag is a hunting-horn blue, and stringed red. The ensign and jack are composed of three horizontal stripes, red, white, and blue.

Norway.—The royal standard is red, with a gold lion crowned rampant and holding in its paws a silver battle-axe. The jack is red, with a blue cross fimbriated white. The ensign is similar, only three-pointed instead of square. The merchant flag is rectangular, with the vertical members of the cross nearer the hoist than the fly, thus making the two horizontal members of unequal length.

Poland.—Two horizontal stripes, white and crimson.

Portugal.—The national flag of the republic is divided vertically into two parts, green and red, in the following proportions: length 3, breadth 2, green 5, red 8. On the intersecting line of the colours is placed a banded sphere, and on it a red shield with seven gold castles placed in orle, and in the centre a white shield charged with five small blue shields in cross, each charged with five silver roundels. The jack is square, with a red centre charged with the banded sphere and shields as above, and surrounded by borders of green.

Russia.—The national flag of the Soviet republic is red, with the letters P. C. F. C. P. in the upper left-hand corner. The imperial standard was yellow, charged with a black double-headed eagle displayed, bearing on its breast a red shield with St George and the Dragon, being the arms of Moscow, the shield being surrounded with the Collar of St Andrew. The wings were charged with eight escutcheons containing the arms of different provinces of the empire. The ensign was white, with a blue St Andrew's Cross. The jack was red, with a white cross surmounted by a blue saltire fimbriated white. The merchant flag was composed of three horizontal stripes, white, blue, and red.

Serbs, Croats, and Slovenes (Kingdom of the).—A long oblong flag, its height being double its width; three horizontal stripes, red, white, and blue.

Siam.—A broad blue horizontal stripe between two narrower white ones, with as many red at the top and bottom of the flag.

Spain.—The royal standard is purple. In the centre, on an oval shield, and ensigned by a crown, are the royal arms, the shield being surrounded by the Collar of the Order of the Golden Fleece. The ensign has a broad yellow horizontal stripe between two narrower ones of red, the former being charged with an oval shield with the arms of Castile and Leon impaled thereon and surmounted by a crown. The merchant flag is yellow, with two red horizontal stripes.

Sweden.—The royal standard is three-pointed, blue with a yellow cross, in the centre of which is a white square bearing the royal arms. The ensign is the same, without the royal arms. The national flag is oblong instead of three-pointed, and the yellow cross is borne in the same fashion as the blue cross of Norway.

Switzerland has only an ensign, which is red, with a white Greek cross, the arms of which do not extend to the edges of the flag.

Turkey.—The imperial standard was red, with an

oblong rayed design in white in the centre. The ensign and merchant flag is red, with a white crescent and star.

United States of America.—The national flag, which is used as ensign and merchant flag, has thirteen horizontal stripes alternately red and white. In a blue canton, in the top corner of the flag next the hoist, are forty-eight white stars. The jack is a plain blue flag with the same number of stars.

The following are the flags of the principal British dominions; the colonies and dependencies of the empire have each an armorial badge, which is superimposed on the fly of whatever British ensign it may be proper to use. When the border of the badge is of the same colour as the ensign, the former is put within a white circle:

Irish Free State.—Three vertical stripes of green, white, and orange.

Australia.—The Commonwealth of Australia bears the blue ensign as a national flag, with five stars (the Southern Cross) on the fly and a large six-pointed star below the union canton. The merchant flag is similar, but red. The governor-general's badge, borne on the centre of the union flag in a white circle, is a seven-pointed faceted star in gold, ensigned by a crown and surrounded by a green garland.

New Zealand also bears the blue ensign with four red stars fimbriated white on the fly. The merchant flag is the red ensign with four white stars on the fly.

Canada.—The merchant flag is the red ensign with the badge of the Dominion.

Newfoundland.—The badge represents Mercury bringing gifts from a ship to Britannia, with the mottoes *Terra nova* and *Hæc tibi dona fero*.

Union of South Africa.—A shield with the arms of the Union borne on the fly of the red ensign.

India.—Badge of the governor-general—a many-rayed golden sun, on the centre a five-pointed silver star surrounded by a blue ribbon bearing the words, *Heaven's Light our Guide*, being the motto of the Order of the Star of India, borne on the union flag, and ensigned with an imperial crown.

See **SIGNALLING**.

Flag-captain, in the Navy, is the captain of the admiral's ship in any squadron, and is ordinarily his nominee.

Flagellants, the name applied to those groups of fanatical enthusiasts who, at intervals from the 15th to the 16th century, made their appearance in various countries of Europe, proclaiming the wrath of God against the corruption of the times, inviting sinners to atone for sin by self-inflicted scourings or flagellations, and publicly enforcing this exhortation by voluntarily scourging themselves, as well as by other forms of self-castigation. In large and disorderly bands—frequently headed by priests, and by fanatics in the costume of priests and monks, bearing banners and crucifixes aloft, their breasts and shoulders bare, and their faces concealed by a hood or mask, each armed with a heavy knotted scourge, loaded with lead or iron—they marched from town to town, chanting hymns full of denunciations of vengeance and of woe. In the most public place of each town which they entered they threw themselves upon the earth, and there inflicted upon themselves the discipline of scourging, frequently to blood, and even to mutilation. Each member enrolled himself for thirty-three days, in honour of the thirty-three years of the life of our Lord on earth; and all for the time professed entire poverty, subsisting only on alms or voluntary offerings. These fanatical movements recurred at frequent intervals; the most remarkable, however, are three in number. The first originated at Perugia in 1260, at a time when society in Italy was greatly

disorganised by the long-continued struggles of the Guelph and Ghibelline factions. Numbers crowded to follow the new cry, until at last the body became so formidable as to draw upon itself the suspicions of Manfred, the son of Frederick II., by whom it was vigorously suppressed. Later offshoots of the party made their appearance in Bavaria, Austria, Moravia, Bohemia, Poland, and France; when to their extravagant practices they added still greater extravagances of doctrine. In virtue of a pretended revelation, they asserted that the blood shed in self-flagellation had a share with the blood of our Lord in atoning for sin; they mutually confessed and absolved one another, and declared their voluntary penances to be a substitute for all the sacraments of the church, and for all the ministrations of the clergy. The Jews were to them an object of special abhorrence, and suffered dreadfully from their fury in many towns of Germany and the Netherlands. In the second outbreak of Flagellantism, about 1349, the outrages against public decency were much more flagrant than on its first appearance. Men and women indiscriminately now appeared in public half naked, and ostentatiously underwent these self-inflicted scourgings. The immediate occasion of this new outburst of fanaticism was the terror which pervaded society during the dreadful plague known as the Black Death. The same extravagances were again repeated in Upper Germany, the provinces of the Rhine, the Netherlands, Switzerland, Sweden, and even England. Although rigorously excluded from France, these fanatics effected an entrance into Avignon, then the residence of the popes, but were condemned by a bull of Clement VI. The mania gradually subsided, nor do we again find any permanent trace of it till the beginning of the next century. In the year 1414 a new troop of Flagellants, locally called *Flegler*, made their appearance in Thuringia and Lower Saxony, renewing and even exaggerating the wildest extravagances of their predecessors. These new fanatics appear to have rejected all the received religious usages, and indeed all external worship, placing their entire reliance on 'faith and flagellation.' Their leader was called Conrad Schmidt. They rejected not only the doctrines of the church upon the sacraments, but also purgatory and prayers for the dead. Their violence drew upon them the severest punishments of the Inquisition. Many of them were capitally condemned, and Schmidt himself was burned at Sangerhausen in 1414. Their doctrines, comprised in fifty articles, were condemned in the Council of Constance.

These strange extravagances are reprobated by the Roman Catholic Church in common with all other Christian communities; but Roman Catholics (relying on 1 Cor. ix. 27; Col. iii. 5) hold the lawfulness, and even the meritorious character, of voluntary self-chastisement, if undertaken with due dispositions, practised without ostentation or fanaticism, and animated by a lively faith and a firm hope in the merits of Christ. This is the self-castigation known under the name of 'the Discipline'—a form of mortification not unfrequent in the monastic state, and even practised by lay persons, and these sometimes of the highest rank, both in ancient and in modern times. See **PENANCE**.

Cooper, *Flagellation and the Flagellants* (new ed. 1887); and Rohricht in the *Zeitschrift für Kirchengeschichte* for 1877.

Flagellum, a vibratile filament of living matter associated with a cell, whether that be an isolated unit as in most flagellate Infusorians, or an

element in a multicellular organism, as in the flagellate chambers of a sponge. A flagellate cell has in most cases a single flagellum, and two are not uncommon; cilia, however, usually occur in numbers. A cilium is simply bent and straightened again; a flagellum wriggles from side to side with a more complex undulatory contraction and extension. A rudder-like flagellum, driving the cell before it, as in spermatozoa and bacteria, has been called a *pulsellum*; while the commoner type, which draws the cell after it, as seen in many Infusorians, has been termed a *tractellum*. A flagellum is usually locomotor or food-wafting in function, and is an expression and outcome of marked activity in the cell to which it belongs. See CELL, CILIA, PROTOZOA.

Flageolet (Old Fr. *flajol*), the modern form of the old *Flûte à bec*, or straight flute, the simplest kind of which is the tin whistle with six holes. It is said to have been invented by Sieur Juvigny in 1580. The English flageolet has the same scale as the Flute (q.v.). The French flageolet, which at one time was very popular in dance music, is a smaller variety, having only four holes in front, with two behind for the thumbs, and additional keys. Its compass is a little over two octaves from G on the treble stave. The flageolet is not used in orchestral music.

Flag-lieutenant is an officer who, in the navy, performs such duties for an admiral as would devolve upon an aide-de-camp in the army. He is also in charge of signalling. He communicates the admiral's orders to the various ships by signal, and reports when they understand them.

Flag-officer, in the British Navy, is an admiral, vice-admiral, or rear-admiral. He is so called from his right to carry, at the mast-head of the ship in which he sails, a flag denoting his rank. The Lord High Admiral, or the commissioners appointed to fulfil his duty—i.e. the Lords of the Admiralty—fly the Admiralty flag at the main. For an admiral of the fleet the union flag is borne at the main. For an admiral the flag is borne at the main; for a vice-admiral, at the fore; and for a rear-admiral, at the mizzen: the flag varying as described at FLAG.

Flagship, the ship in a fleet which bears the admiral's flag, and therefore forms a sort of centre to which all other vessels must look for orders. It is usually the most powerful vessel in the fleet.

Flagstone, a rock which splits into tabular masses, or flags of various size and thickness, in the original planes of stratification. Flagstones are generally sandstones combined with more or less argillaceous or calcareous matter; some, however, are indurated clays, and others thin-bedded limestones. They are used for paving, cisterns, &c. The most famous are those of Festiniog (North Wales), remarkable for their large size, even grain, and great beauty; those of Yorkshire, also of large size, and of great hardness and toughness; and those of Caithness, which are extremely tough and durable. The Caithness flags belong to the Old Red Sandstone; the Yorkshire are taken from the millstone grit division of the carboniferous system.

Flahault de la Billarderie, AUGUSTE CHARLES JOSEPH, COMTE DE, a French soldier and diplomatist, was born at Paris on 21st April 1785. Entering the army a mere lad, he was rapidly promoted to the rank of aide-de-camp of Napoleon. He distinguished himself in the Peninsular war and the Russian campaign, and in 1813 received the title of Count, and the rank of general of division in the new army. He became an exile after Waterloo; and while in England married a Scottish peeress, the Baroness Keith and Nairne, proprietor of Tulliallan, in Clackmannan-

shire. After the revolution of 1830 Flahault returned to France, entered the household of the king, and was appointed ambassador at Vienna (1842-48). By Napoleon III. he was sent as ambassador to London (1860-62), and made Grand Chancellor of the Legion of Honour. He died 2d September 1870.

Flail. See THRASHING.

Flambard, RANNULF or RALPH, justiciar of England under William II., was a Norman of obscure birth. Although he entered the church, and in 1099 obtained the bishopric of Durham, he did not scruple to make himself the king's man, ministering to his vices and extravagances by cruel and oppressive extortion of the king's subjects. He it was who taught the king to apply the usages of feudalism to the estates belonging to the church. He died 5th September 1128.

Flamborough Head, a promontory of the Yorkshire coast, forming the northern horn of Bridlington Bay, 18 miles SE. of Scarborough (by road 24). It terminates a range of steep chalk cliffs, 300 to 400 feet high. Its rugged sides are pierced with many caverns, and in the sea close by are picturesque chalk rocks, which swarm with sea-birds. On the Head is a lighthouse, 214 feet above sea-level, and 80 feet high, seen 21 miles off. Across the peninsula, ending in the Head, runs a double entrenchment, called Danes' Dyke, but really an ancient British earth-work.

Flamboyant, the latest style of Gothic architecture, which prevailed in France during the 15th and part of the 16th century, and corresponds to the Perpendicular (q.v.) in England. The name is derived from the flame-like forms of the tracery of the windows, panels, &c. (fig. 1). The characteristics of this style are minute and elaborate ornament, combined with general bareness of surface. The crockets, for instance, are generally cut into a great number of small leaves, while they are placed far apart; the mouldings are divided into large empty hollows and small thin fillets and beads; the finials have crockets minutely carved, set upon bare pyramidal terminals; the arch-mouldings are divided into a great number of small members, and want the boldness and decision of the earlier styles.

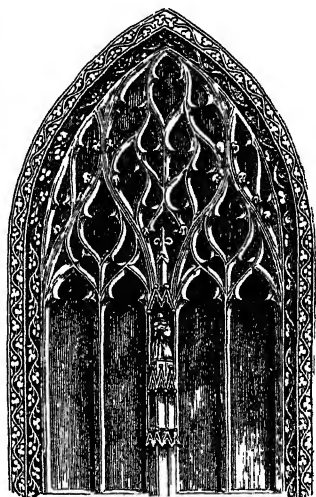

Fig. 1.—Window, Harfleur.

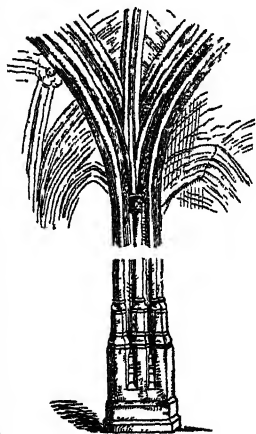

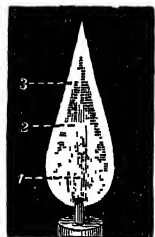

Fig. 2.

These mouldings are frequently abutted on the pillars, or continued down them without any caps; and when there are caps, they are small and without effect (see fig. 2). When mouldings join, they are frequently run through one another, so as to appear to interpenetrate. The effect is intricate rather than beautiful, suggestive of ingenuity in stone-cutting rather than art.

Flame may be defined as a mass or region of glowing gas; and, in so far as terrestrial conditions are concerned, the glow is excited by some exothermic chemical change. Thus the glow which strongly heated iodine vapour exhibits is due to the recombination of its dissociated atoms $I + I = I_2$. Nitrogen also glows and becomes chemically 'active' when subjected to a powerful electrodeless discharge at low pressures, the glow being due to the recombination $N + N = N_2$. Flame is always, however, associated, in the popular mind, with the phenomenon of combustion, and in this restricted sense the glow is excited by interactions in an explosive mixture of combustible gases (or vapours) and oxygen (air). Such interactions probably involve the transient formation of vibratory systems intermediate between the initial reacting mixture

Flame of a Candle: Showing 1, area of non-combustion; 2, area of partial combustion; 3, area of complete combustion.

and the products which finally emerge therefrom. Hence all flames radiate a certain part of the energy liberated during combustion, and are luminous. In no case are the chemical changes concerned instantaneous, and in many cases they involve complex intermediate stages, so that the process is only gradually completed. Hence a certain space (flame-volume) is required, and the temperatures in different regions thereof may be very unequal. The process may be intensified, and the flame-volume diminished with consequent increase in temperature, by various means, such, for example, as (1) the perfect mixing

of the combustible gas and oxygen (air) in proper combining proportions before ignition; (2) pre-heating of the mixtures; (3) the setting-up of 'turbulence' in the mixture before ignition by the influence of compression-waves during combustion.

The simplest type of flame is that propagated through a homogeneous explosive mixture of combustible gas (vapour) and oxygen (air); for each particular mixture there is a certain temperature (the 'ignition' temperature) to which it must be raised before it will 'self-heat' itself by combination, so that if left to itself it will eventually burst into flame. Thus in the case of hydrogen burning in air or oxygen at atmospheric pressure, the ignition temperature is 585°C ., for carbon monoxide 650° , and for acetylene 428° .

Flame is initially propagated from its point of origin for a certain short distance through such a homogeneous explosive mixture, with a slow uniform velocity (e.g. 20 metres per second for a mixture of hydrogen and oxygen in combining proportions, and 2 metres per second for a similar mixture of carbon monoxide and oxygen), each successive layer of the mixture being ignited 'by conduction'—i.e. by admixture with the hot burnt products from the previous layer. This phase of gaseous explosion is usually termed '*inflammation*,' and it is a condition which applies to all ordinary flames. But in the most intense form of flame (*detonation*) the chemical action is propagated from layer to layer by adiabatic compression, with a constant maximum velocity, which, in the case of hydrogen and oxygen in their combining proportions, is 2817 metres per second.

A stationary flame may be obtained (1) by igniting an explosive mixture as it issues from a suitable orifice, with a velocity equal to the velocity of 'back-firing,' or (2) by allowing one of the combining gases to issue into an atmosphere of the other, and igniting the mixture so produced. The case of ordinary 'atmospheric' (Bunsen) burner flames, in which a non-explosive mixture of gas and air is ignited as it issues from an orifice into the air, is intermediate between (1) and (2). In the well-known Meker type of burner an explosive mixture of gas and air in combining proportions (or nearly so) is ignited as it issues from an enlarged burner-head through a deep metal grid; the resulting conical flame is small in volume, and very hot.

The temperatures of flames vary enormously, according to the conditions of combustion, degree of aeration, and region in the flame, and they are only known approximately. Thus, according to Fery's determination, the temperature of a coal-gas Bunsen flame, fully aerated, is 1871°C ., of hydrogen burning in air 1900° , and of acetylene in air 2548° . That of an acetylene-oxygen flame is variously estimated to be between 3000° and 4000°C .

All flames are luminous to a degree, dependent upon the nature of the gas undergoing combustion; the brilliant yellow luminosity of hydrocarbon flames is due to the incandescence of solid carbon particles which are liberated in the flame as the result of the chemical changes occurring therein. The structure of flames has been the subject of much scientific research (*vide* Smithells and Ingle, *Journ. Chem. Soc.* 1892, pp. 204-226), whilst recent developments of the chemistry of the subject were summarised by Professor W. A. Bone in the British Association Reports for 1910.

Singing and Sensitive Flames.—If the flame of coal-gas, or, better still, hydrogen issuing from a blowpipe-nozzle, be slowly passed up a wide glass tube, it will be found that at a particular position up the tube the flame alters its character, being rapidly extinguished and rekindled, while at the same time it gives forth a peculiar musical note. To this is given the name of a *singing flame*. The sound is caused by longitudinal vibrations of the air in the tube, originally set up by a decrease in pressure above the flame, caused by the upward draught; a downflow is thus momentarily produced, which in its turn is checked by the upward motion of the air, and so on.

When an inflammable gas issues from a narrow vertical jet, and is ignited above a sheet of wire-gauze held horizontally about two inches above the orifice, a flame is produced which is easily affected by any sound-waves which strike it, and is hence termed a *sensitive flame*. It will respond to sounds, especially those of high pitch, produced in its neighbourhood, by sinking down to the wire-gauze.

Flamens were priests in ancient Rome devoted each to some special deity. There were fifteen in all. The chief of these (*Flamines Majoeres*) were the flamen of Jupiter (*Flamen Dialis*), of Mars (*Martialis*), and of Quirinus (*Quirinalis*), who were always patricians; the remaining twelve (*Flamines Minores*) were chosen from the plebeians. The flamens were elected at first by the Comitia Curiata, but afterwards by the Comitia Tributa, and were installed into their office by the supreme dignitary of the Roman official religion, the pontifex maximus. The flamen of Jupiter was a privileged person; he was not required to take an oath, was attended by a lictor, his house was an asylum, and he had a seat in the senate. But all this was attended by numerous restrictions: he might not have a knot on any part of his attire, nor touch flour, or leaven, or leavened bread; he might not touch or name a dog, or mount a horse, or be a night out

of the city, &c. His wife, called Flaminica, was subjected to similar restrictions, and when she died the flamen was obliged to resign. The majority of Roman writers attribute the institution of flamens to Numa.

Flamingo (*Phoenicopterus*), a genus of remarkable birds, forming a distinct family, Phoenicopteridae, intermediate between the Anserine birds and the storks. The genus includes eight species, four of which are American (in Chile, Galápagos, Mexico, West Indies, Florida), while the others are distributed in Africa, south Europe, India, and Ceylon. The bill is very peculiar, longer than the small head, and suddenly bent downwards in the middle; the neck is very long and thin; the same adjectives are even more applicable to the legs;

Flamingo (*Phoenicopterus ruber*).

the short toes are webbed. The flamingoes live sociably on marshy shores of the sea, sometimes of fresh water. They stir up the bottom with restless feet, and grub for small animals. In thus fishing, the upper half of the spoon-like bill is turned downwards. The edges of both upper and lower jaw are furnished with small transverse plates, which serve for a sieve, retaining small worms, crustaceans, molluscs, fishes, &c. The upper surface of the tongue is beset on the sides and base with flexible, recurved, horny spines. The flamingoes are birds of powerful flight, and fly like geese in strings or wedge-shaped flocks. They also swim in deep water, but the legs are too long to be well adapted for this purpose. They are habitual waders, and the webbed membrane of the feet helps to support them on soft muddy bottoms. Hundreds feed and nest together, and, being large and richly coloured, form a brilliant assembly, their exquisite pink plumage sometimes making a striking contrast against a background of dark-green mangroves. The nests are mounds of mud, from 8 to 15 inches in height, gradually raised year after year, and built at distances of 3 to 4 feet apart. During incubation the females, it was said, sit with their legs dangling down behind; but Sir H. Blake and Chapman, who watched them carefully, say that the limbs are folded under the birds in the usual fashion. The nesting occurs about the end of May, the hatching about a month later. There is usually only one egg. One species (*Ph. ruber* or *antiquorum*) occurs in Europe, from spring to autumn, on Mediterranean coasts. It measures about 4 feet from bill to tail, and stands about 6 feet high from bill to feet. The male in full plumage is for the most part of a rose-red colour; the female,

and the young for several years, are less brilliant. The young birds were among the delicacies of the ancients.

Flaminian Way (*Via Flaminia*), the great northern road of ancient Italy, leading from Rome to Ariminum (*Rimini*), was constructed by C. Flaminius during his censorship (220 B.C.) in order to secure a free communication with the recently conquered Gaulish territory, and was one of the most celebrated and most frequented roads of Italy during the Republic and of the Empire.

Flammarion, CAMILLE (1842-1925), French astronomer, was born at Montigny-le-Roi, entered the Paris Observatory in 1858, and shortly afterwards made a reputation by his popular lectures and books on astronomy. He wrote also on ballooning, on *The Unknown* (1900), on death and survival (1922), and edited an encyclopædic dictionary.

Flamsteed, JOHN, the first astronomer-royal of England, for whose use the Royal Observatory at Greenwich was built, was born near Derby in 1646. He early devoted himself to mathematics and astronomy with such success as to attract the notice of Sir Jonas Moore, and through him he was appointed astronomer to the king in 1675, in which capacity he endured the unhappy conjunction of too much work and too little pay. The year after, the Observatory at Greenwich was built, and Flamsteed began the series of observations that really commenced modern practical astronomy. He formed the first trustworthy catalogue of the fixed stars, and furnished those lunar observations on which Newton depended for the verification of his lunar theory. Extracts from the papers of Flamsteed, found in the Observatory by Francis Baily, and published by authority of the Admiralty in 1835, brought to light a very sharp quarrel that had taken place between Flamsteed and Newton and Halley with regard to the publication of the results of Flamsteed's labours. His great work is his *Historia Cælestis Britannica*, an account of the methods and results of astronomical observation up to his time, published in 3 vols. in 1723. Flamsteed, while following his scientific pursuits, took holy orders, and in 1684 was presented to the living of Burstow, in Surrey, which he held till his death on 31st December 1719. See Baily's *Account of Flamsteed* (1835).

Flanders (Flemish *Vlaenderen*), the country of the Flemings, a territory lying adjacent to the North Sea, between the Scheldt and the Somme, which embraced the present Belgian provinces of East and West Flanders, the southern portion of Zealand in Holland, and the greater part of ancient Artois in France. This region was originally inhabited by Belgic tribes, on whose subjection by one of Cæsar's lieutenants their territory was incorporated in Roman Gaul. Under the supremacy of Rome they attained to a certain degree of civilisation, being renowned for their agriculture, their industry, and their commerce. The region was afterwards overrun by the Franks on their way to Gaul, many of them settling there permanently. By the Treaty of Verdun (843) Flanders was assigned to Neustria. The real nucleus of Flanders as a political state was the patrimony of a noble family whose possessions were grouped around Bruges and Sluys. In 862 the king of France, as suzerain, changed the title of the head of the family from forester or ranger to count. The first recipient of the honour was Baldwin I., Iron-arm (837-877), who was likewise invested with the maritime region of north-east France, on condition that he defended it against the Normans. His descendant, Baldwin IV. (989-1036), having seized upon the emperor's town of Valenciennes in 1006, and proving himself able to keep what he had

taken, was allowed to retain it (1007) as a feudatory of the empire. At the same time the emperor invested him with Ghent and the Zealand islands (Walcheien, Beverland, &c.). Thus the Count of Flanders held of the emperor as well as of the king of France. Under this count's son and successor, Baldwin V. (1036-67), the county of Alost (Aalst), Tournai, and Hainault were added to the principality. On his death the Netherlands portion of Flanders was erected into an appanage for his younger son, Robert the Frisian, who on the death of his elder brother, Baldwin VI. (1067-70), also wrested Flanders from Baldwin's widow Richilde, leaving to her and her son Hainault only. From this time down to the end of the 12th century the Flemish territories remained thus divided. The counts of Flanders of the 10th and 11th centuries were active in promoting the well-being of their people: they built churches and monasteries, and encouraged the industries of the towns, whereby Flanders rose to be the chief centre of woollen-weaving and fulling in Europe. At this period Ghent, Arras (the capital of the county), Courtrai, Rousselaere, Valenciennes, Cassel, Tournai, Lille, St Omer, Ypres, and Bruges were prosperous cities, the centres of the intelligence and public spirit of the country. Robert II. (1093-1111), son of Robert the Frisian, distinguished himself in the first crusade. His son, Baldwin VII. (1111-19), rigorously suppressed the private feuds of his nobles, and administered justice with Draconian severity. As he left no heir, the county was held by a succession of alien princes, as Charles of Denmark (1119-21); William, son of Robert of Normandy, till 1129; Thierry (Diedrich) of Alsace (1129-69), who took part in more than one crusade; and Thierry's son Philip (1169-91), who, besides championing the Christian faith against the Saracens, did much to foster industry and trade at home.

The accession of these foreign princes was turned to account by the Flemish cities, which extorted from them important charters of liberty and self-government. On Philip's death, Baldwin of Hainault reunited the two Flemish counties under one sceptre. But he had a rival for Flanders proper in Philip of France, who, having married Baldwin's own daughter, the niece of Philip of Flanders, claimed this district as her dowry; and Baldwin was constrained to buy off his more powerful antagonist by the cession of the county of Artois, a large part of southern Flanders, and the towns of St Omer, Hesdin, and some others. From this time forth Ghent superseded Arras as the capital. The next prince of Flanders was Baldwin IX. (1194-1206), son of Baldwin of Hainault, who, after winning back from France most of southern Flanders (though not Artois), took the crusader's cross and became the founder of the Latin empire of Constantinople. Baldwin was followed successively by his two daughters, Johanna (1206-43) and Margaret (1243-78), and by Margaret's son, Guy of Dampierre (1278-1305), who spent a large part of his life as a prisoner in France. Under these rulers the king of France first began to exercise a determining influence upon the government of Flanders. In 1256 the Zealand islands were given to the Count of Holland, and to Holland they have ever since belonged. The next century presents a series of disputed successions, mostly fomented by the kings of France, who made strenuous efforts to unite Flanders to the French crown. The country was in fact divided between two streams of preponderating influence: on the one hand the nobles, headed by the counts, were enamoured of France, and French society, and French institutions (*Lekaerts*); and on the other the burghers of the towns (*Clauwaerts*) clung tenaciously to their national independence and municipal freedom. It was the latter party that con-

stituted the backbone and strength of the country. From the middle of the 12th century the cities, growing more independent and more turbulent with the increase of wealth, began to play an increasingly important part in the politics of Flanders, warring one against another, and even waging civil strife within their own walls, taking up arms against their counts, and by their factions either consolidating or marrying the fortunes of the rulers of the country. It was especially under Johanna and Margaret that the burghers of such cities as Bruges, Ypres, Ghent, and Lille made rapid progress in commercial prosperity and in the establishment of democratic principles of local government. Each of these cities possessed nearly 40,000 looms for weaving cloth; whilst Damme was a thriving seaport, doing a large shipping trade in wool, corn, cattle, wine, beer, &c. The struggle of the cities, represented chiefly by Bruges, Ghent, and Ypres, against the counts and other rulers, lasted more or less down to the Treaty of Utrecht (1713).

Philip IV. of France, having for some years steadily fanned the dissension in Flanders, at length got Count Guy into his hands and took possession of his country (1300), which he governed by means of a regent, Châtillon. This man's oppressive rule, however, provoked a general revolt of the Flemings, who in the battle of the Golden Spurs, fought near Courtrai on 11th July 1302, almost destroyed the army sent against them by the king of France. The contest continued until 1320, during all which time the Flemings successfully repelled the attempts of Philip to invade their country; and at last wholly shook off the claims of France. Under Louis, who became Count of Flanders in 1322, and who neglected his country to spend most of his time at the court of France, the cities frequently broke out into open revolt; Bruges even held Louis a prisoner for several months, nor were the rebels quelled except with the aid of a large French army (1328). In 1336 Jacob van Artevelde (q.v.), who had acquired supreme influence and power in Ghent, induced the chief cities, in defiance of their count, to make an alliance with Edward III. of England to help him in his quarrel with France. From this time down to 1345, when he was slain by a rival in Ghent, Van Artevelde was the real ruler of Flanders, though he found it an impossible task wholly to restrain the violence and disorder in the restless cities. Under Louis II., who succeeded his father, Louis I., in 1346, it was Ghent and Ypres that at first refused to submit to his rule. Then, in 1379, the keen rivalry of Ghent and Bruges came to a head in a civil war, which soon swelled into a general uprising of the entire country, led by the Ghent faction of the White Caps, against the count. The people of Ghent held out stubbornly under Philip van Artevelde, who, however, was slain in battle against the French, 27th November 1382, at Roosbeke. Two years later Count Louis III. died, leaving an only daughter, married to Philip of Burgundy (q.v.), with which duchy the history of Flanders became thenceforward intimately associated, until in 1477, by the marriage of Mary of Burgundy to Maximilian of Austria, both states passed to the empire, Flanders becoming part of Austrian Netherlands. Against this arrangement France vainly protested; and in 1526 she was compelled finally to renounce her claims as suzerain. With the accession of Philip II. to the throne of Spain the history of Flanders becomes identical with that of the Spanish Netherlands (see HOLLAND). By the Treaty of Westphalia Dutch Flanders was transferred to the United Netherlands, whilst by the treaties of the Pyrenees (1659), Nimeguen (1678), and Utrecht (1713) Louis XIV. succeeded in adding to France Artois and a large part of French Flanders. By

this last treaty and by that of Rastatt (1714) the rest of Flanders was assigned to Austria, and became known as the Austrian Netherlands. On the formation of the new kingdom of Belgium in 1831, the provinces of East and West Flanders were incorporated with it.

See Oudegherst, *Chroniques et Annales de Flandre* (1371); Warnkong, *Flandrische Staatsgeschiede* (Tubingen, 1835-39); Conscience, *Geschiedenis van België* (1845); and the more recent works of Kervyn de Lettenhove. For the Belgian provinces of East and West Flanders, see BELGIUM; for the Flemish language, see HOLLAND; and for the Flemish School of Painting, see PAINTING.

Flandrin, JEAN HIPPOLYTE, historical and portrait painter, was born at Lyons, 23d May 1809, the son of a miniature-painter. After studying in his native town, he proceeded in 1829 to Paris, where he attended the School of Fine Arts. But he also worked under Ingres, who was his true master; and from him he imbibed that love of severe and definite form and that classical feeling which he used for his own ends in his religious painting. He had a severe struggle with ill-health, and endured many privations; but in 1832 he won the *Prix de Rome* by his 'Recognition of Theseus;' and before his five years' residence in Italy was completed he had produced his fine rendering of 'St Clair healing the Blind,' now in the cathedral of Nantes. Henceforward he was mainly occupied with decorative monumental work, though he also executed many admirable portraits. In 1842 he began his great frescoes of 'Christ entering Jerusalem,' and 'Christ going up to Calvary,' in the sanctuary of the church of St Germain-des-Prés, Paris, deeply impressive works, which already entitled their painter to rank as the greatest religious painter of the century. The choir of the same church he adorned (1846-48) with figures of the Saints and the Virtues. He also decorated the church of St Paul at Nîmes (1847-49), the church of St Martin d'Ainay at Lyons (1855), and painted the frieze of St Vincent de Paul, in Paris, with a noble series of saints and martyrs. In 1855 he began his last great work in the nave of St Germain-des-Prés, consisting of subjects from the Old and New Testaments, of which some were left uncompleted at his death, at Rome, 21st March 1864. His *Lettres et Pensées*, with a memoir and a catalogue of his works, were issued by the Count Dela-boide, in 1865. See also *Lives* by Poncet (1864) and Montrard (1876).

Flank ('the side'), a word used in many senses in military matters. *Flanks of an army* are the wings, or bodies of men on the right and left extremities. *Flank files* are the soldiers marching on the extreme right and left of a company or any other body of troops. *Flank company* is the company on the right or left when a battalion is in line. *Flanking parties*, or *flankers*, are cavalry or infantry marching some distance from the sides of the main column to prevent a sudden attack upon them.—*Flank*, as applied in Fortification, will be best described under that article. Generally it is any part of the works from which fire sweeps, or flanks, the front of any other part. The *flanks of a frontier* are certain salient points on it, strong by nature and art, between which an enemy dare not penetrate, at the risk of their garrisons attacking his rear, and cutting off communication between him and his base.—In manœuvring, 'to flank' is either to protect the flanks of one's own army by detached bodies of troops, or field-works, or to threaten those of the enemy by directing troops against them. To *outflank* is to succeed by manœuvres in overlapping the flank of an enemy who has been, on his part, endeavouring to flank one's own force.

Flannan Islands, or THE SEVEN HUNTERS, a small group of uninhabited (save for the four persons in the lighthouse) islets off the outer Hebrides, 20 miles NW. of Gallion Head in Lewis.

Flannel (unlike *flannelette*, an inflammable cotton fabric made in imitation of flannel), a woollen cloth manufactured much like other woollens (not worsteds). For flannel the wool, after passing through the preparatory processes of scouring and devilling, is carded, spun, woven, and fulled or milled. Those kinds with a fleecy pile on the surface are passed through the teasing-machine (see WOOLLEN MANUFACTURES). Yarn for ordinary flannel is loosely spun to impart softness to the fabric. Flannel wears better and shrinks less if the pile is slightly raised than if it is much raised, and it is better to get it of the natural white colour than slightly blued, as this tint gives way at the first washing.

Welsh flannel made from the wool of the Welsh mountain-sheep fetches the highest price. But it is well known that the supply of this wool is not nearly enough to make the quantity of flannel sent into the market as 'real Welsh.' Some of the Lancashire flannels made of other wools are hardly inferior to those made in Wales. Yorkshire flannels are lower in price than either of these. Special kinds of flannel are made, such as the comparatively firmly spun and closely woven flannel for cricket dresses and fancy shirts; thin all-wool gauze flannel for use in India and other warm countries; similar flannel made with a silk warp; dometts made of wool and cotton; and gray, dyed, and printed flannels. The manufacture of flannels is chiefly carried on in England at various places in Lancashire and Yorkshire, and in Wales at Newtown, Welshpool, and Llangollen. Flannel shirtings are made on a considerable scale at Auchterarder in Scotland.

In the United States flannels are manufactured on a very extensive scale. In order to prevent shrinkage these are made of yarns more closely twisted than those used for English flannels. American flannels are also less highly fulled, and smoother in the face. The French excel in the manufacture of fine dyed flannels. On the Continent, also, a substitute for flannel is made of the fibre of the leaf-needles of the Scots Pine (see FIBROUS SUBSTANCES).

Flat, a musical character, shaped thus ♭, which, when placed before a note, lowers that note half a tone. The double flat, ♭♭, lowers a note two semitones. Singing or playing is called flat when the notes are at all below the right pitch.

Flat, a story or floor of a building, especially when fitted up as a separate residence for a family; four, six, or more such dwellings (often only half-floors) being approached by a common stair. This tenement system is much more common in Scotland and on the Continent than in England, though of late years it has been largely adopted in London, both in the richer and in the poorer districts. In New York and other large American towns, besides the older tenement houses, there are more expensive modern flats, often fitted with conveniences unknown in similar houses in Europe.

Flatbush, a former township of Long Island, adjoining Prospect Park, Brooklyn, with a lunatic asylum, was annexed to Brooklyn in 1894, and with it is now a part of greater New York.

Flat-fish (*Pleuronectidae*), an important family of marine bony fishes, in the order Anacanthini, with the body compressed from side to side, and markedly unsymmetrical. The turbot (*Rhombus maximus*), the halibut (*Hippoglossus vulgaris*), the flounder, plaice, and other members of the genus *Pleuronectes*, and the soles (*Solea*) are well-known

examples, valuable as food-fishes. There are about three dozen genera and two hundred species. They occur in all seas, and some thrive in fresh water. The adults keep to the bottom, especially on sandy coasts, and come nearer shore in the spring spawning season and during summer. They are all carnivorous. Many of them alter the colour of their exposed upper side in sympathetic and automatic adjustment to the nature of the ground on which they lie concealed. They are all destitute of a swim-bladder, but the most remarkable feature is the asymmetry of the skull, eyes, and musculature. Unlike the gristly skates, which are flattened from above downwards, the Pleuronectidæ are flattened sideways, and swim or rest on one side, either right or left. The under side is virtually uncoloured, the upper side is often markedly pigmented, and bears both the eyes. The young forms, however, are striking contrasts to the adults. They are almost transparent, occur in the open sea, are quite symmetrical, with an eye as usual on either side, and swim vertically. With increasing size the normal structure and habit are lost, the fishes become asymmetrical, and keep to the bottom. While the skull is still gristly and plastic it is twisted, and the lower eye comes to lie beside its fellow on the upper surface. The exact mechanism is not yet clear. See FISHES, FLOUNDER, PLAICE, SOLE, TURBOT, &c.

Flatheads, a term officially but incorrectly applied to the Salish Indians, a small tribe dwelling on Clarke's Fork, in Idaho. The men are industrious and willing to learn, and have become good farmers; preferring peace, they nevertheless make brave warriors, but have never fought against the whites. A grammar of their difficult language has been published by Mengarini (New York, 1861). The term Flatheads refers to the very ancient practice of flattening the skulls of young infants by various mechanical means, such as was prevalent in Peru, both before and after the arrival of the Incas, among the Caribs in Central America and Mexico, in Florida, and among the mound-builders of the Ohio and Mississippi valleys. Among modern Indians it is mostly confined to the Chinooks (q.v.) and other tribes of the north-west coast of North America.

Flattery, CAPE, a headland of Washington state, U.S., washed on the NE. by the Strait of Juan de Fuca, and on the SW. by the Pacific.

Flatulence, distension of the stomach or bowels by the gases formed during digestion. See INDIGESTION.

Flaubert, GUSTAVE, who is considered by competent judges the most remarkable French novelist of the second half of the 19th century, was born at Rouen on the 12th December 1821. He was the son of a physician of eminence, and inherited, though not wealth, a fortune sufficient to enable him to choose his own way of life. He hesitated long between his father's profession and literature; and in literature he began with poetry, which, however, he definitely gave up before long for prose. Flaubert's life was extremely uneventful in outward incident, the turning-point of it being, according to his intimate friend M. Maxime du Camp (whose account, though traversed by some of Flaubert's other friends, seems to be accurate in the main), the access when he was still a young man of some obscure form of brain-disease, which altered, and even to some extent arrested, his intellectual development. M. du Camp goes so far as to hold that almost all the original part of Flaubert's work was conceived, if not actually sketched, before this time. But however this may be, Flaubert was a very late producer, and his work, when it did appear, was marked by a very

strong and somewhat morbid idiosyncrasy. He had comparatively early (before 1849) written some fragments of a work only completed much later on the Temptation of St Anthony, but his first published book was the famous novel of *Madame Bovary*, which appeared in 1857. This is the history of a girl of some education, with strong aspirations after elegance of life and depth of passion, whose fate condemns her to live in the country as the wife of a well-intentioned but utterly stupid and commonplace doctor. Her successive lapses into vice, her desertion by each of her lovers, her extravagance, and her final suicide form the central part of a story, the outline of which is filled up by a series of the most wonderful studies of scene and character, charged with satiric melancholy, and expressed in an extraordinarily careful and vivid style. Style, indeed, was the object of Flaubert's main devotion, and as he advanced in years he for the most part shut himself up in his small country-house near Rouen to wrestle, as his own favourite phrase expressed it, with the language which was to clothe his thought. Although *Madame Bovary* is not constructed according to English ideas of decorum, its license in that respect does not exceed what had long been common in French, and the author was most indignantly surprised at its prosecution as an offence against morals, a prosecution which did not succeed. His second work, *Salammô* (1862), dealt with the last struggle of Rome and Carthage. The author had taken immense pains to study the locality and all the authorities; and he put into his book in consequence an amount of archæological detail and local colour which sometimes seems to overweight the story. *Salammô* is moreover deeply tinged with the sombre horror which was one of Flaubert's notes.

In 1866 Flaubert was decorated with the Legion of Honour. Three years later *L'Éducation Sentimentale*, a much longer book, appeared, but was far less popular. No book of Flaubert's displays more accurate observation of life, but the absence of central interest and the disheartening effect of a mere succession of disillusionments undergone by the hero make it a book for few. In 1874 appeared the splendid phantasmagoria of *La Tentation de St-Antoine*, worked up from the early fragments already referred to, and the masterpiece of its kind; while in the same year the author produced a play, *Le Candidat*, with little success, and of no merit. In 1877 there followed his last book (exclusive of posthumous work), *Trois Contes*, which represents all his best manners; the first tale, on the daughter of Herodias, being a *Salammô* in little, *Un Cœur Simple* displaying all the power of *Madame Bovary* with a perfectly harmless subject, and *St-Julien l'Hospitalier* being in the same vein as the *Tentation*, with the addition of something like a central thread of interest. Flaubert died on May 9, 1880, and after his death appeared a novel, *Bouvard et Pécuchet*, which had not received his final revision, and which is somewhat undigested. It tells of the attempts of two retired men of the middle class to interest themselves in literary and scientific researches. There has been published (also posthumously; trans. 1922) an extremely interesting correspondence with George Sand; and other letters throwing much light on Flaubert's character have followed. In his last years he was a member of a small set of distinguished writers (the other three being the great Russian novelist Turgenieff, M. Daudet, and M. Zola), who frequently met, and who acquired the reputation as of a sort of headquarters-staff of what has been successively called realism and naturalism in fiction. Flaubert, however, never belonged to either of these schools, least of all to

that of naturalism. His minute and exhaustive description was indeed a point in common with both; but this description was always subordinated to a strictly romantic conception of the general scheme of story-telling. Flaubert was in fact a pure romanticist who came late and had engrafted on the earlier romanticism not a few characteristics rather inherited than borrowed from Balzac on the one hand, and Stendhal on the other. It is improbable that any more remarkable examples of this combined mode will ever be created than *Madame Bovary* and *Salammô*, each in its kind, though from the mere fact of the combination it follows that some readers will fix their attention most on the realism, others on the romance. A splendid 'édition définitive' of Flaubert's works was issued in 1909-12. See work by J. C. Tarrver (1895).

Flavel, JOHN, an English Nonconformist divine, born at Bromsgrove in Worcestershire, most probably in 1630, was educated at University College, Oxford, took Presbyterian orders in 1650, and had already held livings at Diptford (in Devon) and Dartmouth, when he was ejected by the Act of Uniformity of 1662. He continued to preach privately at Dartmouth, and after the Declaration of Indulgence (1687) was minister of a Nonconformist church there till his death at Exeter, 26th June 1691. He was four times married. His writings were long popular, and do not entirely deserve the neglect into which they have fallen. His best books are the *Treatise on the Soul of Man*, *The Method of Grace*, *A Token for Mourners*, and *Husbandry Spiritualised*. An edition in 6 vols. was issued in 1820.

Flavian Cæsars were Vespasian (q.v., Titus Flavius Vespasianus) and his sons and successors, Titus and Domitian.

Flavine, a concentrated preparation of quercitron bark imported from America. Until recently it was an important yellow dye, but cheaper colouring materials are now being substituted for it. See DYEING. It has been tried as an antiseptic for wounds, but with less satisfactory results than had been hoped for.

Flax (*Linum*), the typical genus of Linaceæ, a sub-order of Geraniaceæ, consisting of about 140 species of annual and perennial herbaceous plants, with a few small shrubs, all inhabitants of temperate climates, most abundant in Europe and northern Africa. Some are cultivated as showy

articum, an annual weed, is the Purging Flax, long a standard resource of domestic medicine. But all essential interests centre round the Common Lint or Flax, well named by Linnæus *L. usitatissimum*, since in its importance for civilised man it rivals the staple food plants. There are two main varieties or sub-species—*vulgare* and *humile*—the latter distinguished by its shorter and more branched stems and rather larger leaves, but more easily by its larger capsules, which burst open when ripe with a characteristic sound, so scattering the seed. Though shorter, this yields the finer, softer, and whiter fibre. In both the flower is a loose corymb of beautiful blue flowers. *L. austriacum* is also cultivated in France, *L. maritimum* in southern Europe, and *L. Levisii* in North America, but all yield a coarser fibre. The flax of prehistoric times found in the Swiss pile-dwellings, and in the remains of the stone age in northern Italy, was derived from *L. angustifolium*, as not only the manufactured product but the actual remains of the stems, fruit, and seeds clearly show. The common lint of the Aryan peoples was, however, *L. usitatissimum*, and the occurrence of the name lint with little modification in all European languages is usually interpreted as indicating that its use dates from the remote antiquity of their common home. The same culture is shown by an examination of the mummy-cloths of Egypt, which are always of linen; and the species is also recognisably delineated upon the walls of the tombs.

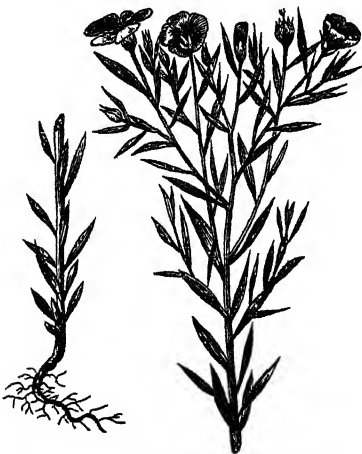

The quantity of flax produced in Great Britain, once large, had become quite negligible before the war of 1914-18. Several thousand acres were grown under war conditions, but it seems doubtful whether the cultivation of the crop has been permanently re-established. In Ireland the area was much more considerable, but had sunk from over 300,000 acres in 1863 to about 50,000 before the war, practically all in Ulster. The area in Ireland was doubled during the war, but again it is doubtful whether the increase will prove permanent. Russia was by far the greatest flax-producing country before the war. The area exceeded 5,000,000 acres, and was increasing. Germany, Belgium, Holland, France, Austria, Hungary, and Italy all produced considerable quantities, ranging from 70,000 to 250,000 acres, but the areas in every case, except that of Hungary, were decreasing.

In Europe flax is cultivated both for fibre and for seed. In India, the United States, Argentina, and Canada the crop is grown mainly for seed.

For an account of the mode of preparation of its bast as a textile fibre, see below; for processes of manufacture, see LINEN; and for a description of the useful applications of its seed, see LINSEED, OILCAKE, OIL.

FLAX-DRESSING.—Growing stems of flax are not cut by scythe or reaping-machine, but pulled up by the roots. The best time for doing this is when the stalks begin to turn yellow at the base, and the seeds begin to change from green to a pale brown. A heavier crop is obtained when the plant is riper, but the quality of the fibre is injured. It is of importance that the stems of equal length should be separated, uniformity in this respect simplifying the dressing processes.

Rippling, the process of removing the seeds, follows the harvesting. The ripple, or rippling-comb, consists of a row of round iron teeth set in a wooden frame which is fixed to a plank. In length the teeth are about 18 inches, and at the pointed tops they are about half an inch apart. The rippler, taking up a bundle of flax, spreads out the tops like a fan, and generally draws first the one half of it and then the other through the teeth, a sheet being placed on the ground to receive the seeds or bolls as they fall. One or two machines

Common Flax (*Linum usitatissimum*).

garden annuals—e.g. *Linum grandiflorum*, &c., while the allied *Radiola millegreana* (Allseed) is the smallest of our phanerogamic weeds. *L. cath-*

have been introduced for rippling flax. One of these removes the seeds by passing the stems between two cast-iron cylinders. Another performs the operation by means of beaters which loosen the seeds, and shakers which then shake them out of the bundles of flax-staw.

Retting is the name given to the next process in the treatment of the stems of flax. Its object is to facilitate the separation of the useful fibre from the boon or woody part of the stem through the removal, by fermentation, of the gummy or resinous matters present in the plant. This is done either by dew-retting or by water-retting with or without the aid of heat. Dew-retting consists in spreading the flax on the grass, and exposing it to the influence of dew, rain, air, and light for a considerable time. It is a method practised in Russia, and produces a soft and silky fibre. Water-retting or steeping is the plan most generally followed. Soft water is essential, and the dam or pond should not be more than four feet deep. In this the flax bundles or 'beets' are placed in rows, roots downwards, and then covered with weeds or straw weighted with boards and stones, or with turf and stones, to keep the flax below the water. If the weather is warm fermentation begins soon, a change which causes the flax to rise in the water, and it must then be more heavily weighted. The flax sinks again as the fermentation slackens, the extra weight being then removed. Great judgment is required to determine when the retting has proceeded far enough. The stems are examined with much care, and if one finds on breaking them at one or two places, or twisting them in the middle in opposite directions, that the woody core called 'shore' or 'shive' separates freely from the fibre, the flax is ready for removal from the pond. From ten to fourteen days are required for the process with water at ordinary temperatures. The smell that accompanies the process is most offensive, and water in which flax has been steeped is valuable as a liquid manure.

A quicker process of retting, in which water at a temperature of 75° to 90° F. is used, was introduced by an American, R. B. Schenck, in 1847. Wooden vats are employed, and the fermentation goes on so much more rapidly that the time of steeping is reduced to from 50 to 60 hours. By another invention (Pownall's) the flax is passed between heavy rollers after it is taken from the vats, clean water being kept flowing over the stems during the operation to remove the gummy matters. Schenck's method is not much favoured now.

Grassing follows the ordinary retting process. The flax stems are spread in rows of thin layers upon short grass for a few days, during which time they are sometimes turned with a pole; but if this is not done, the tips of the stems of one row should overlap the root ends of the next. The flax is lifted when it is found that a slight rubbing suffices to separate the woody core from the fibre.

Breaking.—After the retted stems are dried they undergo 'breaking' to prepare them for the scutching process. One simple and efficient machine for breaking consists of two pairs of horizontal fluted rollers—one pair having finer flutes than the other—mounted in a frame, and turned by the necessary gearing. There is also a feed-table. In passing between the rollers the brittle woody parts of the stems are broken throughout their length. Later breaking-machines have more numerous fluted rollers, some of which have a reciprocating motion. The more efficiently the breaking is performed the less will be the amount of scutching required.

Scutching.—The woody matter of the flax stems being broken up and ready to be separated from the fibrous portion, this is done either by hand-scutching or, as is chiefly now the case, by scutching-

machines. In the hand-process the flax is hung up in such a position that it can be struck repeatedly with the blade of a scutching-knife, so as entirely to remove the woody portion. In scutching-mills—which are usually driven by water-power—the scutching is performed by a series of vertical wheels, on each of which are mounted a few wooden blades projecting considerably beyond the rim. These blades take the place of the scutching-knife, and work against wedge-shaped projections in a partition, striking the flax in the direction of its length, a workman sliding the 'broken' flax gradually forward as the scutching proceeds. Besides this arm-scutch in scutching-mills there are scutching-machines of more elaborate construction used in the dressing of flax. Brushing-machines are sometimes employed to give the flax a final cleaning before baling it for the market. For the manufacture of flax into cloth, see LINEN, and SPINNING.

Flax, NEW ZEALAND, a valuable fibre quite different from common flax, and obtained from the leaf of a monocotyledonous, instead of the stem of a dicotyledonous plant. The plant yielding it is *Phormium tenax*, often called New Zealand Flax, and sometimes Flax Lily and Flax Bush (Harakeke of Maoris). It belongs to the order Liliaceae, and is an evergreen growing wild over large areas, and very easily cultivated, even upon the poorest soils; it has also been introduced into southern France and Dalmatia, and is familiar in colder climates as

New Zealand Flax (*Phormium tenax*):
a, inflorescence; b, separate flowers, enlarged.

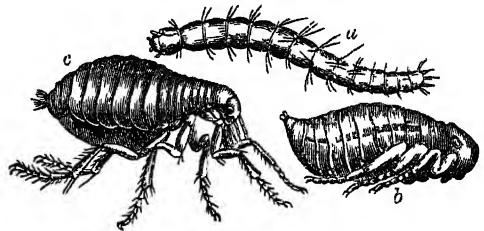

a decorative plant in greenhouses and sheltered gardens. Its leaves resemble those of an Iris, and are from two to six feet long and one to two or three inches broad. The flowers are produced in a tall branched panicle, and are numerous, brownish-yellow, and not very beautiful; the fruit is a three-cornered capsule, with numerous compressed jet-black seeds. The fibre of the leaves is both very fine and very strong, and was used by the New Zealanders, before their country was discovered by Europeans, for making dresses, ropes, twine, mats, cloth, &c. New Zealand flax is imported into Britain for making twine, ropes, sailcloth, and other uses to which its strength and durability alike well adapt it. To obtain the fibre the leaves are cut thrice yearly, and the fibre is easily separated by maceration. But the New Zealanders procure the fibre in its greatest perfection, very long and slender, shining

like silk, by a more laborious process, and without maceration, removing the epidermis from the leaf when newly cut, separating the fibres by the thumb-nails, and then more perfectly by a comb. The root stocks are bitter and purgative, and have been used as a substitute for sarsaparilla. The leaves, when cut near the root, exude a viscid juice, which becomes thick and gummy, and is then eaten; the New Zealanders prepare a sweet beverage from the flowers.

Flaxman, JOHN, R.A., sculptor, was born at York, 6th July 1755. His father, a moulder of plaster figures, removed to London when his son was six months old; and the delicate, slightly-deformed child, confined to home-pleasures and stimulated by the works of art which surrounded him, soon developed a taste for drawing. Seated in his little chair behind the counter, with his crutches by his side, he attracted the attention of some of his father's customers. The Rev. Mr Mathew found him attempting to teach himself Latin, and forthwith befriended him, introducing him to his cultured and refined home-circle, where his wife read Homer and Virgil to the boy. At the age of ten his health greatly improved, and he devoted himself to art. In 1767 and 1769 he exhibited models at the Free Society of Artists, and in the latter year he was admitted a student of the Royal Academy, whose silver medal he won in 1770, when he began to contribute to its exhibitions. From this period he was constantly engaged upon works of sculpture; but patronage was long of coming, and from 1775 till 1787 his chief source of income was the Messrs Wedgwood, whom he furnished with exquisite designs and decorations for their pottery, work for which he was admirably fitted by his unrivalled skill in modelling in relief. In 1782 he quitted the parental roof, established himself in a small house and studio in Wardour Street, and married Ann Denman, a cultivated and estimable woman, who was his true helpmate for thirty-eight years. He now began to be employed upon monumental sculpture, into which he infused much of pathos and of grace. Among his works of this class may be named his monument to Chatterton, in St Mary Redcliffe, Bristol; to Collins, in Chichester Cathedral; to Mrs Morley, in Gloucester Cathedral; and to the memory of Miss Cromwell. By 1787 he had gained enough by his art to warrant a visit to Italy, and, accompanied by his wife, he proceeded to Rome, and studied there for seven years. During this period he executed a group of Cephalus and Aurora; his ill-remunerated group of 'The Fury of Athamas,' from Ovid; and his restoration of the Hercules torso; and began his great series of designs to the *Iliad* and the *Odyssey* (published 1793), to *Æschylus* (1795), and to Dante's *Divina Commedia* (1797), which were engraved in Rome by Piroli, under his own supervision, and widely extended his fame. They were followed by his designs to Hesiod, engraved by Blake in 1817. Returning to England in 1794, he occupied himself upon his fine monument to Lord Mansfield, in Westminster Abbey. In 1797 he was elected R.A., in 1800 R.A., and in 1810 he became professor of Sculpture to the Royal Academy. His lectures, which were collected in a volume in 1829, are judicious and well considered, but somewhat wanting in lightness, point, and charm of style. Among the works of his later life are his monuments to Sir Joshua Reynolds, to Lord Howe, and to Lord Nelson; 'Michael and Satan,' his most important example of ideal sculpture, executed for Lord Egremont; and his drawings and model for his great 'Shield of Achilles,' completed in 1818. He died 7th December 1826, and was buried in the church of St Giles-in-the-Fields, London.

Personally Flaxman was a man of extreme gentleness, modesty, and courtesy; simple and abstemious in his tastes; devout in spirit, a follower of Swedenborg. See Allan Cunningham's *Lives of the Most Eminent British Painters, Sculptors, and Architects*, vol. iii. (1830); and Sir Sidney Colvin, *The Drawings of Flaxman in Thirty-two Plates, with Descriptions and an Essay on his Life and Genus* (fol. 1876).

Flea, a name applicable to any member of the small order Siphonaptera or Aphaniptera, of which *Pulex irritans* is a familiar example. They are wingless insects, probably related to flies; with long, slender, serrate, piercing mandibles, an unpaired sucking tube (the labrum), and long labial palps, forming a sheath. It is believed that the irritation produced by a flea-bite is partly due to the introduction of micro-organisms which occur in the salivary glands of the flea. The compressed shape of the body, the long, powerful, bristly legs, which are able to take such relatively gigantic leaps, and the abdomen with eight rings bearing bristles may be readily perceived on the common species; while microscopic examination will show the biting and sucking mouth-appendages, the small eyes and minute antennæ, and two pairs of little bristly scales, like remnants of wings, on the second and third segments of the thorax. The eggs, usually not numerous, are laid in safe corners, or in the fur, feathers, &c. of the animal infested; the hatching is rapid (six to twelve days), and bristly, footless larvæ emerge; after a few (eleven) days' voracity

Metamorphoses of Common Flea (*Pulex irritans*), magnified:

a, larva; b, pupa or nymph; c, perfect insect

these form cocoons, and so rest in pupa quiescence for variable periods. In summer the entire development of *Pulex irritans* occupies about a month. The larvæ feed on waste animal matter. The fleas are all ectoparasitic on warm-blooded animals, and the numerous species are more or less rigidly confined to particular furred and feathered hosts. The flea that chiefly troubles man is *Pulex irritans*, that of the cat and dog is *P. serraticeps* (which seems to be an intermediate host of a dog tapeworm); *P. avium* is common on birds. The rat-flea of India (*Xenopsylla cheopis*) seems to convey the bacillus of Plague (q.v.) from rat to rat, and from rat to man. The common English rat-flea (*Ceratophyllus fasciatus*) transmits a trypanosome from rat to rat. The muscular energy of these pests has been utilised in 'flea-exhibitions,' in which tamed captives drag miniature carriages, and perform similar exercises. As regards their leaping powers, Kirby and Spence have the following note: 'Aristophanes, in order to make the great and good Athenian philosopher, Socrates, appear ridiculous, represents him as having measured the leap of a flea.' In our better times scientific men have done this without being laughed at for it, and have ascertained that, comparatively, it equalled that of the locust, being also two hundred times its (the flea's) length.' Where fleas prevail in spite of cleanliness, recourse may be had to insecticide

preparations, the modern substitutes for the old-fashioned fleabane and wormwood. The more formidable Chigoe (q.v.) or Jigger is separately noticed. See Taschenberg, *Die Flohe* (1880).

Fleabane (*Pulicaria*), a genus of Compositæ (sub-order Tubulifloræ, family Inulææ), readily recognised by a peculiar aromatic smell, sometimes compared to that of soap, which is said to be efficacious in driving away fleas. There are two British species, *P. vulgaris* and *P. dysenterica*, and the latter has a considerable reputation in diarrhoea and dysentery. *Conyza squarrosa*, also called fleabane, belongs to a closely allied genus.

Flèche, in French, a spire generally, is also used specially for the slender spire that sometimes rises from the intersection of the nave and transepts of large churches. For a good illustration, see COLOGNE.

Flèche, LA, a town of France, in the department of Sarthe, on the Loir, 60 miles N.W. of Tours by rail. It has manufactures of paper, starch, leather, and sabots, and since 1764 has been the seat of a famous military school (*Prytanée*), founded in 1607 as a Jesuit college, where Eugene of Savoy and Descartes were educated. Here, too, are the heart and a statue (1857) of Henri IV.; and here David Hume spent three years (1734-37). Pop. 10,000.

Fléchier, ESPRIT (1632-1710), Bishop of Nîmes (1687), was born at Peines, and shone as a pulpit orator. See studies by A. Fabie (1882-86).

Flecker, JAMES ELROY, poet and dramatist, was born in London, 5th November 1884. He was educated at Uppingham and Trinity College, Oxford, and at Caius College, Cambridge, where he studied Oriental languages. He entered the Consular service, lived at Constantinople, Smyrna, Beirut, and elsewhere in the East; but consumption drove him to Switzerland, and he died at Davos Platz, 3d January 1915. His works, influenced by the Parnassians, include *The Bridge of Fire* (1907), *Forty-two Poems* (1911), *The Golden Journey to Samarkand* (1913), *The King of Alexander* (1914), *The Old Ships* (1915), *Collected Prose* (1920), two plays: *Hassan* (1922) and *Don Juan* (1925). See J. C. Squire's introduction to the collected *Poems* (1916), books by Goldring (1922) and Hodgson (1925).

Flecknoe, RICHARD, a Roman Catholic, possibly an Irishman and a priest, who after some ten years' travels in Europe, Asia, Africa, and Brazil (1640-50) came to London, mingled in the wars of the wits, wrote plays, and died about 1678. His name is now remembered (apart from Marvell's satire) only as that of the stalking horse over whom Dryden applied the merciless lash of his satire to Shadwell, the most virulent of his literary assailants. Dryden's famous satire, *MacFlecknoe*, is partly the model of Pope's more famous *Dunciad*. Flecknoe is represented as seeking for a successor to the throne over the realms of nonsense, on which he had long sat supreme, and as having fixed on Shadwell as the one of all his sons best fitted for it.

Fleet (that which floats), a collection of ships, whether of war or commerce, for one object or for one destination. 'Division,' 'subdivision,' and 'squadron' are portions of a fleet. In the royal navy of Great Britain a fleet is ordinarily the command of an admiral or vice-admiral, and should, strictly speaking, consist of ten ships or more of the first class, with an appropriate number of battle-cruisers, light-cruisers, torpedo-boat destroyers, submarines. Great Britain maintains a fleet in the Channel and another in the Mediterranean; whilst the number of her war-ships in the West Indies, India and China, and the Pacific enables these squadrons to assume the dimensions of a fleet by very trifling additions from other quarters.

Fleet Prison, a celebrated London gaol, which stood on the east side of Farringdon Street, on what was formerly called Fleet Market. The keeper of it was called the Warden of the Fleet. It derived its name from the Fleet rivulet (O.E. *fleot*, 'a bay'; afterwards applied to any shallow stream where small craft could float), which flowed into the Thames. The Fleet was the king's prison so far back as the 12th century. In the 16th century it acquired a high historical interest from its having been the prison of the religious martyrs of the reigns of Mary and Elizabeth; and the victims of the Star Chamber were confined here in the reign of Charles I., and numbers of Puritans in that of his son. Afterwards it became a place of confinement for debtors and persons committed for contempt from the Courts of Chancery, Exchequer, and Common Pleas. During the 18th century it was the scene of every kind of atrocity and brutality, from the extortion of the keepers and the custom of allowing the warden to underlet it. The Fleet was several times rebuilt; the last building was erected after the burning of the older one in the Gordon riots of 1780, the predecessor of which had been destroyed in the great fire of London in 1666. In 1776 Howard found here 243 prisoners, their wives and children numbering 475; there were also 78 outdoor *détenus* for debt, privileged to live within the 'rules.' In 1830-34 the annual number confined in the Fleet for debt ranged from 700 to 884. The prison was abolished in 1842, and the debtors transferred to the Queen's Bench, under the new name of the Queen's Prison. The buildings were demolished in 1845-46, and part of the site is now occupied by the Congregational Memorial Hall.

FLEET MARRIAGES.—The practice of contracting clandestine marriages was very prevalent in England before the passing of the first marriage act (see MARRIAGE). The chapels at the Savoy and at May Fair, in London, were long noted for the performance of these marriages; but no other place was equal in notoriety for this infamous traffic to the Fleet Prison. The first notice of a Fleet marriage is in 1613, and the first entry in a register is in 1674. Up to this time it does not appear that the marriages contracted at the Fleet were clandestine; but in the latter year, an order having been issued by the ecclesiastical commissioners against the performance of clandestine marriages in the Savoy and May Fair, the Fleet at once became the favourite resort for those who desired to effect a secret marriage. At first the ceremony was performed in the chapel in the Fleet, but by 10 Anne, chap. 19, sect. 176, marriages in chapels without banns were prohibited under certain penalties, and from this time rooms were fitted up in the taverns and the houses of the Fleet parsons for the purpose of performing the ceremony. Sir W. Besant's romance gives a vivid description of the persons who celebrated these marriages—real or pretended clergymen of the Church of England, who had been consigned for debt to the prison of the Fleet, and who shamelessly employed touters to bring to them such persons as required their office. The sums paid for a marriage varied, according to the rank of the parties, from half-a-crown to a large fee. During the time that this iniquitous traffic was at its height every species of enormity was practised. Young ladies were compelled to marry against their will; young men were decoyed into a union with the most infamous characters; and persons in shoals resorted to the parsons to be united in bonds which they had no intention should bind them. Registers of the marriages were kept by the various parties who officiated; a collection of these books, purchased by government in 1821, is deposited at Somerset House. In 1840 they were declared inadmissible as evidence in a court of law.

Various ineffectual attempts were made to stop the practice by acts of parliament, and at length, the nuisance having become intolerable, in 1753 an act was passed which struck at the root of the matter by declaring that all marriages, except in Scotland, solemnised otherwise than in a church or public chapel, where banns have been published, unless by special license, should be utterly void. The public, however, were unwilling to surrender their privilege, and on the 26th March 1754, the day before the act came into operation, there were no less than 217 marriages entered in one register alone. See Burn's *History of Fleet Marriages* (1833), and Ashton, *The Fleet: its River, Prison, and Marriages* (1888).

Fleetwood, or FLEETWOOD-ON-WYRE, a modern seaport and trawling centre of Lancashire, at the mouth of the Wyre, 21 miles NW. of Preston by rail. Founded in 1836, it has an excellent harbour, and is a favourite resort for sea-bathing. Steamers ply to Belfast and the Isle of Man. Within the town is a lighthouse, the light, 90 feet high, being visible for 13 miles. Rossall School (q.v.) is two miles to the south-west. Pop. (1851) 3121; (1911) 15,875; (1921, in holiday season), 19,448.

Flegel, EDUARD ROBERT, explorer, born of German parentage at Wilna, 13th October 1855, made it the principal object of his life to acquire for Germany the preponderating share of the commerce of the Niger. His first ascent of this river was made in 1879, in the steamer of the London Missionary Society, and his second a year later, when he reached Sokoto by a left-hand tributary of the river. But his next journey, in 1883, was the most fruitful in results, for during the course of it he discovered the sources of the Benue, to the south of Adamawa. After a short visit to Europe, he again started for Africa in April 1885, having been commissioned by the German African Society and Colonial Company to explore the country stretching between the sources of the Benue and the Cameroons; it was also his intention to penetrate from the Benue to the Congo, but he was suddenly stricken down by death, near the mouth of the Niger, on 11th September 1886.

Fleischer, HEINRICH LEBERECHE, Orientalist, was born at Schandau, in Saxony, 21st February 1801. Having studied theology and oriental languages at Leipzig, he was for some years after 1828 engaged in cataloguing the oriental MSS. in the royal library at Dresden, the catalogue being published at Leipzig in 1831-34. After acting for five years as teacher in a school at Dresden, Fleischer was appointed professor of Oriental Languages at Leipzig in 1836. He edited Abulfeda's *Historia Moslemica* (1831-34), the continuation of Habicht's edition of the original of the *Thousand and One Nights* (vols. ix.-xii. 1842-43), Ali's *Hundred Sayings* (1837), Baidhavi's *Commentary to the Koran* (1846-48), and wrote an account of the Arabic, Persian, and Turkish MSS. in the town library of Leipzig, printed in Naumann's *Catalogue* (1838); also a *Critical Dissertation on Habicht's Glosses to the First Four Volumes of the Thousand and One Nights* (1836). He died 10th February 1888.

Fleming, JOHN, naturalist, born near Bathgate, Linlithgowshire, in 1785, entered the ministry, was professor of Natural Philosophy at Aberdeen, 1832-43, and filled the chair of Natural Science in the New College, Edinburgh, from 1845 till his death in 1857. His works include the *Philosophy of Zoology* (2 vols. 1822), a *History of British Animals* (1823), and *Molluscos Animals* (1837).

Fleming, PAUL, German poet, was born 5th October 1609 at Hartenstein, in Vogtland. He

studied medicine at Leipzig, and accompanied embassies sent by the Duke of Holstein to Russia and to Persia. He returned in 1639, married, and resolved to settle as a physician in Hamburg, but died there, 2d April 1640. Fleming stands at the head of the German lyric poets of the 17th century. His *Geistliche und weltliche Poemata* (1642) contain many exquisite love-songs, which for more than a century remained unequalled in finish and sweetness. Others are full of glowing enthusiasm, ardent patriotism, and manly vigour, while his sonnets are marked by strength and thorough originality. The most complete collection is that of Lappenberg (2 vols. 1866), who had already edited his Latin poems in 1863.

Flemings, Flemish. See FLANDERS, BELGIUM, HOLLAND (*Literature of*), PAINTING, and for Flemish Bond, see BRICKLAYING.

Flensburg (Danish *Flensborg*), a port in the province of Sleswick-Holstein, at the extremity of Flensburg Fjord, an inlet of the Baltic, 19 miles N. of the town of Sleswick. Its principal industrial establishments embrace iron and machine works, copper and zinc factories, shipbuilding yards, brick, cement, and lime works, and breweries; fishing and fish-curing are also carried on. Along with Sleswick-Holstein, Flensburg passed from Denmark to Prussia in 1864. It elected to remain German in 1920. Pop. (1875) 26,525; (1890) 36,894; (1919) 60,941.

Flers, a town of France, in the department of Orne, 41 miles S. of Caen by rail. It has large spinning, brick and tile establishments, and is the centre of a busy manufacturing district, where linen and cotton goods, especially fustian and tickings, are produced. It contains a sixteenth-century castle, which was burned down in the Chouan war, but since restored. Pop. 13,000.

Flesh. While in common parlance the term flesh is applied to those parts of the body composed of muscular tissue (see MUSCLE), it is, in physiological language, used as a term including all the living protoplasmic matter of the body which has a chemical composition closely resembling that of muscle. This use of the word (*Fleisch*) we owe chiefly to the Munich school of physiologists, who have done so much to advance our knowledge of the chemical changes in the tissues. In such investigations the terms loss of 'flesh,' gain of 'flesh,' &c. are to be understood in this inclusive sense.

This flesh has something of the following composition:

Water	75	per cent.
Solids	25	"
Inorganic	1	"
Organic	24	"
Proteins	16-19	"
(Nitrogen)	3-4	"

Flesh-fly. See BLUE-BOTTLE, and FLY.

Fleta, the title of an early treatise on the law of England, presumably written about 1290 by a judge who was confined in the Fleet prison. It consists of six books, the language being Latin. Selden edited it in 1647.

Fletcher, ANDREW, of Salton, a famous Scottish patriot, was born in 1655, the son of Sir Robert Fletcher, himself of English descent, and of Catharine Bruce, whose father, Sir Henry Bruce of Clackmannan, was directly descended from Robert Bruce. His father dying when he was still an infant, he was brought up under the care of the celebrated Gilbert Burnet, and early imbibed his preceptor's passion for political freedom, but not his prudence. After some years of continental travel, he sat in parliament in 1681 as commissioner for his native county, and offered so determined an opposi-

tion to the measures of the Duke of York that he found it necessary to flee to England, and thence to Holland. Here he formed fast friendship with the refugee English patriots, and on his return to England in 1683 shared the counsels of Russell, Essex, Howard, Algernon Sidney, and John Hampden, the greater patriot's grandson. Though a republican, Fletcher was very far from being a modern democrat, for one of his favourite schemes was to utilise the hosts of vagrants and paupers of the time like the slaves of ancient Greece and Rome. On the discovery of the Rye-house Plot, Fletcher fled to Holland, returned as a volunteer with Monmouth, but was obliged almost at once to leave the army for having at Lyme shot a fellow-campaigner in a personal quarrel about a horse. He now fled to Spain, but had no sooner landed at Bilbao than, at the instance of the English ambassador, he was flung into prison, from which he was soon mysteriously delivered by an unknown guide. In disguise he passed through Spain, not without further more than romantic adventures, in Hungary distinguished himself greatly as a volunteer against the Turks, and returned to Scotland at the revolution. He was the first patron of William Paterson, the founder of the Bank of England and projector of the Darien expedition, and it was the bitterness caused in Scotland by the base treatment the unfortunate Darien colonists received from King William's government that gave Fletcher and the nationalist party their strength in the struggle against the inevitable union with England. His famous 'limitations' aimed at constructing a federative instead of an incorporating union—a frail structure that would have borne neither the burden of recent irritation nor the weight of ancient hatreds. Fletcher's orations in the Scottish parliament still glow with eloquence, and carry the stamp of genuine sincerity, but the modern reader has feelings other than admiration for a statesman whose eyes were too much blinded by prejudice to recognise that the only salvation for a country distracted by intestine jealousies and hopelessly corrupt domestic government lay through incorporation with the larger and healthier life of the great southern kingdom. After the consummation of the union, Fletcher retired in disgust from public life, devoting himself to promoting agriculture. His fanners for winnowing corn and his mill for making *pot-barley* were better gifts to his country than all his speeches. He died at London in the September of 1716. His writings were collected and reprinted at London in 1732. Fletcher is described as follows by a contemporary pen: 'He is a low, thin man, of a brown complexion, full of fire, with a stern, sour look; of nice honour, with abundance of learning, brave as the sword he wears, a sure friend and an irreconcilable enemy, would lose his life readily to serve his country, and would not do a base thing to save it. His thoughts are large as to religion, and not such as can be brought within the bounds of any particular set, and his notions of government are too fine-spun, and can hardly be lived up to by men subject to the common frailties of nature. Fletcher of Salton's name survives popularly only in the famous but usually misquoted saying, in his *Account of a Conversation concerning a Right Regulation of Governments for the Common Good of Mankind*: 'I knew a very wise man, so much of Sir Christopher's sentiment, that he believed if a man were permitted to make all the ballads, he need not care who should make the laws of a nation.' See the Life by G. W. T. Omond (1897).

Fletcher, GILES and PHINEAS, poets, were cousins of Fletcher the dramatist, and sons of Giles Fletcher, LL.D. (1549-1611), himself a poet and writer on Russia, and Queen Elizabeth's

minister in negotiations in Germany and at the court of Russia.—GILES, the younger of the two brothers, was born about 1588, was educated at Trinity College, Cambridge, and died at his living at Alderton, in Suffolk, in 1623. Fuller tells us that his 'clownish low-parted parishioners, having nothing but their shoes high about them, valued not their pastor according to his worth, which disposed him to melancholy and hastened his dissolution.' His chief poetical work is a sacred poem, entitled *Christ's Victory and Triumph in Heaven and Earth over and after Death*, published at Cambridge in 1610. It is full of splendid versification and imagery, and is saved from the fatal dullness of most professedly religious poems by a quickening glow of genuine enthusiasm. It is of course based upon Spenser, and most of his distinctive characteristics are imitated and overdone. The metre is original and not entirely successful. Each stanza has eight lines, the last an Alexandrine, rhyming thus: *ababbecc*; and a lyrical interlude occurs here and there. The poem, although once admired, is now unknown to general readers, and is chiefly remarkable for having to some extent influenced the majestic muse of Milton. His poems were edited by Dr Grosart in 1868 and in 1876, by Dr F. S. Boas in 1908-9.—PHINEAS was born in 1582, educated at Eton and King's College, Cambridge, and in 1621 became rector of Hilgay, in Norfolk, where he died in 1650. His most important poem, the *Purple Island, or the Isle of Man*, was published in 1633, in twelve cantos of seven-lined stanzas, a regular elegaic quatrain taking the place of the irregular quintet of Giles's poem. It contains an elaborate description of the human body, given with great anatomical minuteness. The body is an island, the bones its foundations, and the veins the streams by which it is watered. The vices and virtues that affect it are similarly allegorised with laborious ingenuity. Although to a large extent formal and pedantic, the *Purple Island* abounds in fine passages. Phineas Fletcher's poetical works were edited by Dr Grosart in 1868, by Dr F. S. Boas in 1908-9.

Fletcher, JOHN (1579-1625). See DEAUMONT AND FLETCHER.

Fletcher, JOHN GOULD, poet and art critic, born 3d January 1886, at Little Rock, Arkansas, studied at Harvard, lived for a time in Massachusetts, and settled in London in 1916. His earlier works—e.g. *Irradiations* (1915)—overflowing with fantasy, placed him among the Imagists. Later collections, such as *Breakers and Granite* (1921) are more human in interest.

Fleur-de-lis, a heraldic device representing the white lily, came to be the arms of the Bourbons and of France. The three heads of the fleur-de-lis have been said to typify the Trinity. See PEWS.

Fleurus, a town of Hainault, on the Sambre, 15 miles W. of Namur, the scene of three great battles: (1) in 1622, when the Germans, under the Fleur-de-lis. Duke of Brunswick and Count Mansfeld, defeated the Spaniards; (2) in 1690, when the French, under Luxembourg, routed the allied Germans and Dutch, commanded by the Prince of Waldeck; and (3) in 1794, between the French, under Jourdan, and the Austrians and their allies, under the Duke of Coburg, on which occasion the latter, although he had virtually beaten his antagonist, gave the signal to retreat.

Fleury, or FLORY, in Heraldry, signifies that the object is adorned with fleurs-de-lis; a cross-fleury, for example, is a cross the ends of which are in the form of fleurs-de-lis. See CROSS, TREASURE, &c.

Fleury, ANDRE HERCULE DE, CARDINAL, Louis XV.'s prime-minister, was born in 1653, at Lodève, in Languedoc, became in 1677 almoner to the queen, and after her death (1683) filled the same post under Louis XIV., who in 1698 made him Bishop of Fréjus. Under Louis's will he was appointed preceptor to the heir-apparent, a child of five years, who in 1715 succeeded as Louis XV. In 1726, at the age of seventy-three, Fleury was raised by the young king to be prime-minister; in the same year he received the cardinal's hat. Fleury was honest and well meaning, but not a statesman: the extortions of the farmers-general were not checked, although it was probably for the people's sake that the minister practised a rigid economy that approached avarice and even crippled the power of France; whilst in foreign affairs he was earnestly desirous of peace, and yet was dragged by court intrigues into two wars over the succession to foreign thrones (see SUCCESSION WARS). The war of the Austrian Succession was not finished when he died, 29th January 1743, in the ninetieth year of his age, leaving the king thenceforth to the unchecked guidance of his mistresses. Fleury was an academician, and the friend and patron of learning; he sent out two expeditions to measure arcs of the meridian, gathered rare MSS. from Egypt and Greece, and completed the Bibliothèque Royale (now Nationale). See Verlaque, *Histoire du Cardinal Fleury* (Paris, 1879).

Fleury, CLAUDE, church historian, was born at Paris in 1640, and forsook the law for an ecclesiastical career. In 1672 he became tutor to the young Princes de Conti, and at a later period to the Comte de Vermandois, natural son of Louis XIV. After the death of the young count in 1683, the French monarch appointed Fleury abbot of the Cistercian monastery of Loc-Dieu, and afterwards, under Fénelon, tutor to the Dukes of Burgundy, Anjou, and Berri. He was elected to fill La Bruyère's place in the Academy in 1696; and ten years later, on the completion of the prince's education, he was rewarded with the priory of Argenteuil. The Duke of Orleans selected him for confessor to the young king, Louis XV., giving as his reason for so doing that Fleury was neither Jansenist, nor Molinist, nor Ultramontanist, but Catholic. He died 14th July 1723. Fleury was as learned as he was modest, and as mild and kind-hearted as he was simple in his manners and upright in his conduct. Among his numerous works may be mentioned *Mœurs des Israélites* (1681); *Mœurs des Chrétiens* (1662); *Institution du Droit Ecclésiastique* (1687); and, above all, the *Histoire Ecclésiastique* (20 vols. Paris, 1691-1720). On this work, really the first complete and systematic history of the church, its organisation, doctrines, and rites, Fleury laboured thirty years. It is marked by great learning, and, on the whole, by a judiciously critical spirit. The work was translated into many languages, and praised by orthodox and heretics, both for its matter and style. Fleury's own work only reached to 1414; it was continued to 1778 by Fabre, Lacroix, and others.

Flevo, LAKE. See ZUIDER ZEE.

Fliedner, THEODOR, founder of the Protestant order of Deaconesses (q.v.), was born in Nassau in 1800, and in 1822 became pastor of Kaiserswerth, near Düsseldorf, where in 1836 he founded the first deaconesses' home and a seminary for infant-school teachers, besides other institutions. He died 4th October 1864.

Flies. See FLY, ANGLING.

Flight of Animals. (1) BIRDS.—Newton proved that the resistance of the air to a body moving through it increases as the square of the

velocity. It is this characteristic of air that makes flight possible.

As gliding is simpler than flapping-flight, it will be best to investigate it first. If a bird has gained momentum by plying his wings and wishes to glide onward maintaining his altitude, he gives his wings their full spread and inclines his body and wing-surfaces slightly upward. The resistance of the air acts at right angles to a moving plane, so that in this case resistance will take mainly the form of support. As the angle of incline is reduced, the resistance becomes less, and the line which represents it approximates more closely to the vertical—i.e. the amount of *lift* becomes more and more disproportioned to the amount of *drift*. It might seem, then, that the bird might with advantage reduce the angle of incline almost to the vanishing point if only he could sufficiently increase his pace. But the question of friction comes in. When the angle is less than, approximately, 5°, with the necessary velocity, friction becomes so great that more power is required than when the angle is slightly greater. It is the anterior part of the wing that does most of the work. This part meets the air first and sets it in motion. The air, thus disturbed, passes over the posterior part and offers little resistance. When a bird wishes to glide downward, he partly flexes his wings; thus reduced in width, they give less support.

Owing to the curve of the wings from front to back (their camber), the support given by the air is much greater than it would be if the surface were flat. The big heavy flyers have less supporting surface per lb. weight than the lighter and smaller. In proportion to its weight, a gnat has a greater supporting-surface than a butterfly; the butterfly comes far ahead of the swallow. In this respect the gnat, the butterfly, the swallow, the pigeon, the stork must be arranged thus in descending scale. The reason is not far to seek. The swallow's wing, though much larger, relatively to the weight to be carried, than the stork's, is *absolutely* very small, and a small wing lets the air escape at the margins. If the swallow were put on a par with the stork in point of the wing-surface allowed per lb. weight, his power of flight would be gone.

Owing to the massing of the heavy flight-muscles on the breast, the bird's centre of gravity is placed low, and it has been maintained that this produces automatic stability. But this is not so. The elasticity of the feathers helps to produce lateral stability. If a sudden gust puts more pressure upon the right wing than on the left, the feathers, yielding and bending upward, reduce the wing area on that side, and so diminish the pressure. But equilibrium is maintained chiefly by voluntary adjustments, though these movements, no doubt, through habit become almost unconscious. If a gull hanging over the stern of a steamer is watched, it will be seen to be perpetually making slight adjustments. Some birds, notably pigeons, often glide with their wings sloped upwards, and this position may tend to preserve equilibrium. Photography, too, has shown that it frequently happens that the wings give unequal or different strokes. For fore-and-aft balance the tail is very useful; when it is expanded and lowered it follows that the hind-quarters are raised by the pressure of air while the head is lowered. Long-legged and long-necked birds can do much by extending or retracting their legs or necks. Webbed-feet can be used to some extent as the tail is used, and as they are heavy their retraction or extension may have some effect. It is remarkable that birds with long legs or webbed-feet have small tails. The contrast between a sparrow-hawk and a heron in this respect is very striking. In gliding the wings can be

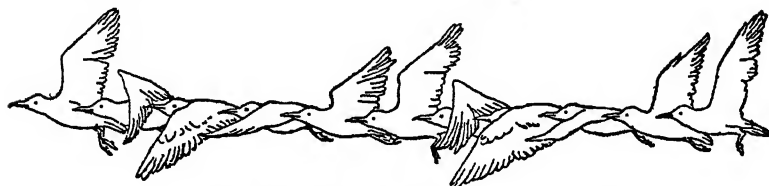

effectively used: if they are partly flexed the centre of pressure moves backward; when they are fully extended again it moves forward.

In order to support and propel himself, a bird must move his wings with extreme rapidity. They are levers, and a fulcrum has to be found on the yielding air. If a very rapid stroke is given, the air resists and a fulcrum is obtained. As with most levers in living animals, the object is not to economise power, but to obtain rapidity of movement. The great muscle which lowers the wing springs from the breast-bone and the keel and attaches to the humerus not far from its near end. When it contracts the farther end of the wing moves with great velocity. When a stork is giving what seem very leisurely flaps, the bending back of the primary feathers proves with what speed and force they are being driven through the air. A fulcrum is being found, and mainly beneath the end of the wing. The muscle that raises the wing is, comparatively, quite small, and lies in the angle formed by the sternum and the keel. It attaches by a tendon to the front edge of the upper surface of the humerus, and its pull raises the wing on the pivot formed by the shoulder-joint. When once the bird has gained momentum, the elevator-muscle has little work to do, since, after the down-stroke, the resistance of the air carries the wing backward and upward. When the down-stroke is about to begin (see figure), the wing stands erect with its anterior edge turned to the front. Attaching to

bicels or hooklets, and this interlocking gives to the feather its firm texture, and, in part, its elasticity.

Most birds have strong legs of some length, and this enables them to jump from the ground and start flying. The puffin, the swift, and the condor may be mentioned as birds which have difficulty in starting from the ground owing to shortness or weakness of leg. The stork, mounted on the top of his long legs, is able to move his wings freely from the first. But in all cases birds of great bulk have difficulty in mounting steeply upward. Their wing-strokes are, of course, comparatively slow. The buzzard, according to Marey, takes 3 per second to the sparrow's 13. The heron, as a rule, takes about 130 per minute. Thus, when he has but little way on, the bulky bird loses altitude between the strokes. He, therefore, gets up pace, ascending by a gentle incline. Moreover, most bulky birds are very stiff at the shoulder-joint and, were they to incline their bodies steeply upward with a view to a rapid ascent, their wings, not having sufficient power of rotation, would beat, not up and down, but forward and backward. The wings of most small and of some fair-sized birds have great freedom at the shoulder-joint—e.g. the pheasant, which has occasion often to rise almost vertically to an opening in the boughs overhead. On the other hand, the grouse and the gull, living as they do in the open, are stiff at the shoulder; they can afford to mount gradually.

A bird has various ways of steering. In order to steer to the left he will commonly fling himself on his left side, the left wing pointing downward and the right upward. His onward course in the former direction of his flight is checked by the expanse of his wings, and he travels

Gull flying (after Marey), 25 photographs per second.
Reproduced by permission from Headley's *Flight of Birds* (Witherley).

the anterior edge of the humerus the depressor-muscle tends to lower the front of the wing more than the back, and the air, acting upon the large expanse of feathers behind the supporting bones, helps to bring this about. Since the resistance of the air acts at right angles to the wing, and since the wing is inclined, from front to back, upward, the bird is not only supported, but propelled; there takes place a resolution of forces. But the wing not only descends; it moves forward—the action of the air upon its inclined surface brings this about, and it results that the incline from tip to base is upward; for propulsion this is just what is wanted. In hurried flight this forward movement of the wing is very conspicuous; in leisurely flight the wing moves but little forward as it descends, the stroke being much shorter. When the down-stroke is over, the muscles relax, and the wing is immediately carried backward and upward by the force of the air. It is then moved forward edgewise and erected by the elevator-muscle. In the course of the up-stroke, the backward movement is sometimes checked for a moment, for photographs show the flight-feathers bent back. The object may be to prevent the bird dropping between the wing-strokes. During the down-stroke the flight-feathers rotate slightly, so that the inner web of each presses closely against the feather above it, with the result that the wing becomes impervious to air. This rotation is mainly due to the fact that the inner web is broader than the outer, and so is more strongly acted on by the air. In each feather the barbules (the secondary branches that spring from the barbs) interlock by means of bar-

onward head leading. The tail is also used in steering, one side or the other being lowered. Good steerers, such as the sparrow-hawk, have a far larger spread of tail than bad steerers, such as the duck. Unequal wing-strokes, which not infrequently take place, must also play an important part in steering.

When a bird wishes to stop and alight, he suddenly drops his hind-quarters, and his wings are so orientated that their beating speedily checks his momentum. At the moment of alighting the wings are often given a final stretch as if to ease the muscles after their exertions. In the case of the tern, the lapwing, and even the domestic pigeon this is a beautiful sight.

Birds' wings vary much in form and efficiency. There is the short, broad, rather primitive wing which suffices for short flights—e.g. the jay's; for long-distance flight the narrow tapering wing with the camber vanishing towards the tip—e.g. the golden plover's; the broader but pointed wing of the great soaring birds.

Flight with Motionless Wings.—Gulls may often be seen hanging over the stern of a steamer, their wings outstretched and motionless, except for slight movements necessary for the maintenance of equilibrium, and keeping pace with the vessel. When this happens, there is a head wind, or one which strikes the vessel at a small angle. Impinging against the vessel's side, it is deflected upward, as can be shown by letting fly small pieces of paper, and the gulls poise upon the up-current. The air acts at right angles to the bird's expanded surface, which is inclined slightly down-

ward, and thus not only supports him but gives him headway. In hill country or over sun-heated plains big birds, such as kites, vultures, eagles, may be seen turning in spirals, sometimes rising not only when they are facing the wind, but throughout a complete turn of the spiral. If it is a left-handed spiral, the left wing is sloped downward and the right is in line with it. The primary wing feathers are bent upward. There is no flapping of the wings when the conditions are favourable. In the neighbourhood of hills there are, of course, up-currents at the service of the soaring bird, and the performance, however marvellous, has an obvious explanation. The circling keeps the bird within the region of the up-current or within range of some spot which he has under observation. From sun-heated plains the air rises, and may give the wind an upward tiend. When clouds obscure the sun, kites and other soarsers descend or resort to flapping flight. A good observer on the plain of Upper Assam states that there is always a wind when soaring takes place there. Dr Hankin (*Animal Flight*), who has made very painstaking observations in India, says that birds often soar when there is no wind. But apart from wind there may be a strong up-draught. In any case we cannot accept his testimony when he maintains that he has seen a bird rising with wings held motionless in a descending current. The upward bending of the primary feathers, always noticeable, can be accounted for only by an up-draught. There is no soaring over the sea, and there the up-currents due to heat are but feeble. The wind is deflected by waves, and this fact the shearwater and, probably, the albatross turn to account. Unequal velocities in a horizontal wind would not enable a bird to dispense altogether with the flapping of his wings. Near the ground the velocity of the wind increases rapidly with altitude. The snipe, when he rises facing the wind, profits by this; emerging from a slower current into a faster one, he has the inertia that he must have if a horizontal breeze is to help him. Yet he has to ply his wings vigorously. However, Lanchester, a high authority, holds that inequalities in the wind's velocity may be utilised by the soaring bird in addition to up-currents.

(2) BATS.—All five metacarpals and all the digits except the thumb help to form the framework of the bat's wing. Behind, it is attached to the leg, and this makes the bat a poor starter. The wing-strokes are rapid, and the flight quick.

(3) FLYING-FISH.—They often fly for a distance of 200 yards. Much longer flights are recorded. The fish jumps from the water propelled by a strong movement of his tail. Often he flies low over the water, propelling himself by the action of his tail, which at intervals is immersed in the water. But not seldom he makes higher flights, and sometimes lands himself on the deck of a ship. In these cases there is no doubt that the large pectoral fins are used, vibrating with great rapidity. Dissection has shown that the requisite muscles are strongly developed. No doubt flying-fish often take advantage of up-currents of air due to the deflection of the wind by the waves.

(4) INSECTS.—The flight of insects is in principle similar to that of birds. But the smaller area of the wings necessitates a very rapid stroke. Marey, as the result of ingenious experiments, gives the following rates per second: common fly 330, bee 190, wasp 110, humming-bird moth 72, dragon-fly 28, butterfly 9. Evidently the muscles of insects that fly are capable of much more rapid contraction than those of vertebrates.

Books to consult: *Le Vol des Oiseaux* and *Animal Mechanism*, by Prof. Marey; *Aerodromics*, by F. W. Lanchester; *The Flight of Birds*, by F. W. Headley. For human flight see BALLOONS and AEROPLANES.

Flinders, MATTHEW, an English navigator, who surveyed a great portion of the Australian coasts, was born at Donington, in Lincolnshire, 10th March 1774, and in 1790 entered the navy. Going out to Australia in 1795, he determined to investigate the coast south of Port Jackson, about 250 leagues of which were laid down in the charts as 'unknown.' With an equally daring and ambitious young surgeon in the ship, named Bass, he carried out a series of voyages, the most important result of which was the discovery of a previously unknown strait between Van Diemen's Land (now Tasmania) and the mainland of Australia, which was named after Bass. In 1801 Flinders obtained from the British government the command of a scientific expedition for the investigation of the Australian coasts and their products. Commencing his examination at Cape Leeuwin, Flinders in the course of two years gradually explored the coast to Bass Strait (q.v.), thence northwards—laying down carefully the Great Barrier Reefs—to the Gulf of Carpentaria, which he thoroughly surveyed across to Timor, then back to Cape Leeuwin, and round the south coast to Port Jackson (1803). On his way home he was first wrecked, and then detained a prisoner by the French governor of Mauritius, and not allowed to proceed to England until 1810. He gave the world the result of his explorations in *A Voyage to Terra Australis*, and died July 19, 1814, the day on which his book was published.—The coast of South Australia was long called after him Flinders Land. His name is still attached to the southernmost county in Eyre Peninsula, and to Flinders Island, off that coast; to the Flinders Range in South Australia, rising near the head of Spencer Gulf, and running north (highest peaks, 3100 feet); also to a town in Victoria, 61 miles S.E. of Melbourne. See Life by Ernest Scott (1914).

Flindersia, a genus of trees of the order Rutaceæ, or, according to others, Meliaceæ, natives of eastern Australia, New Caledonia, &c. Some are valuable shade trees; some afford timber useful for cabinet-making. *F. Australis* is the Native Ash or Crow's Ash of Australia; *F. Oxleyana* (or *Oxleya xanthoxyla*), the Queensland yellow-wood or white teak.

Flint, a mineral which may be regarded as a variety of quartz, allied to chalcedony, consisting almost entirely of silica, with traces of carbonaceous impurities whose presence gives rise to the prevailing dark colour. It has a flat shell-like fracture, is translucent or semi-translucent, and varies in colour from a very dark brown, or almost black, to light brown, red, yellow, and grayish-white, and is sometimes veined, clouded, marbled, or spotted. Dark-coloured flints are most common in the chalk, in which principally flint occurs imbedded, forming tabular sheets and nodules of various sizes, sometimes large nodular masses, of irregular and often grotesque shape; but gravel formed of light-coloured flints is very common, and it is disputed whether or not a change of colour has taken place by exposure to atmospheric and other chemical agencies. Flint is sometimes found in beds or veins. It is very abundant wherever the chalk formation extends, in England and other countries; rolled flint nodules are also often found in conglomerate rocks, and in alluvial soils—vast alluvial tracts being sometimes full of them. Flint geodes often contain crystals of quartz. Flint nodules are usually moist in the interior if broken when newly taken from their beds.

Flint is sometimes harder than quartz, sufficiently so to scratch it. The readiness with which it strikes fire with steel is well known, and it would seem that the sparks are not all merely incandescent particles, heated by the friction, but that in some of them a chemical combination of silica and iron takes place, causing great increase of heat. The use of the flint and steel for igniting tinder was superseded by that of lucifer matches, and gun-flints gave place to percussion-caps—themselves now superseded. The most ancient use of flint was probably for sharp weapons and cutting instruments; and flint knives, axes, arrow-heads, &c. are among the most interesting relics of rude antiquity. In East Anglian churches squared flints have been used for centuries to ornament the porches, towers, buttresses, &c.; but at present the principal use of flint is in the manufacture of fine earthenware, into the composition of which it enters, being for this purpose first calcined, then thrown into cold water, and afterwards powdered.

The origin of flint is a subject of considerable difficulty. Siliceous deposits are sometimes the result of a purely chemical operation, as in the case of the siliceous sinter formed round the geysers of Iceland, from the evaporation of water largely charged with silica. But at the bottom of the sea, as no evaporation could take place, some other agent than springs of water saturated with silex must have supplied the materials. It is a fact of considerable importance in this inquiry that almost all large masses of limestone contain siliceous concretions, or flints. Thus, chert is found in Carboniferous and other limestones, and menilite in the Tertiary limestones of the Paris Basin. The conditions necessary for the deposition of calcareous strata seem to be those required for the formation of siliceous concretions. The materials of both exist in solution in sea-water, and, as it needed the foraminifer, the coral, the brachiopod, and the mollusc to fix the carbonate of lime which formed the chalk deposits, so the silex was secreted by innumerable diatoms and sponges, and their remains most probably supplied the material of the flint. The discovery by Dr Bowerbank and other microscopists of the spicules of sponges and the frustules of diatoms in almost every specimen of flint has clearly shown that flint to a large extent, if not entirely, owes its origin to these minute organisms. After the death of the organisms their silica appears to have been redissolved and redeposited, perhaps through the agency of decomposing animal matter, sometimes in the form of irregular concretions, and sometimes replacing the calcareous skeletons and exuviae of other organisms. See FLINT IMPLEMENTS AND WEAPONS.

Flint, a borough and seaport in the east of Flintshire, North Wales, on the left side of the estuary of the Dee, 13 miles by rail NW. of Chester. In the vicinity are very extensive alkali-works, besides copper-works, collieries, and lead-mines. Pop. 6300. Till 1918 it united with Caergwrle, Caerwys, Holywell, Mold, Overton, Rhuddlan, and St Asaph in sending one member to parliament. Flint Castle, built by Edward I., captured by the parliament in 1643, and four years later dismantled, is a ruin. Here Richard II. surrendered to Bolingbroke, 19th August 1399. See Taylor's *Notes on the History of Flint* (1873).

Flint, a maritime county of North Wales, bounded on the NE. by the river Dee, on the E. by Cheshire, on the S. and W. by Denbighshire, and on the N. by the Irish Sea. The main portion of the county is 26 miles long by 10 to 12 broad, and the detached hundred of Maelor, lying 8 miles SE. of the main part, measures 9 miles by 5. Flintshire is the smallest of the Welsh counties, its area

being 256 sq. m. The coast is low and sandy, but along the Dee estuary fertile. The county is bisected by a low range of hills, stretching almost due north. The geological basis consists of rocks of the Carboniferous series. Coal, iron, lead, copper, calamine, zinc, and limestone are the chief mineral products. Some chemical works and potteries of coarse clay give employment. There are numerous well-watered and picturesque valleys, the soil of which is for the most part fertile and well cultivated. The uplands afford good pasturage. The Dee in the east and the Clwyd in the west of the county are the principal rivers. Pop. (1801) 39,469; (1881) 80,587; (1911) 92,705; (1921) 106,466. Flintshire returns one member to parliament. The chief towns are Flint, Rhyl, Buckley, Connah's Quay, Mold, Prestatyn, St Asaph, Holywell, and Hawarden. Flintshire has traces of Roman lead-mines, and is traversed by Watt's and Offa's Dykes. In the 7th century Saxon invaders massacred all the Christian monks of the monastery of Bangor-iscoed (q.v.). Several barrows and menhirs occur in the county. See D. R. Thomas, *History of the Diocese of St Asaph* (1874).

Flint, capital of Genesee county, Michigan, on the Flint River, 64 miles NNW. of Detroit by rail, with numerous sawmills, and manufactures of automobiles and carriages, cigars, brass, axles, &c. There is a large state institution for the deaf, dumb, and blind here. Pop. (1890) 9803; (1910) 38,550; (1920) 91,599.

Flint, ROBERT (1834–1910), was born (March 14) at Dumfries, educated at the university of Glasgow, and ordained in 1859 to the East Church, Aberdeen, whence he was transferred in 1861 to the parish of Killoonquhar in Fife. In 1864–76 he occupied the chair of Moral Philosophy at St Andrews, and in 1876–1903 that of Divinity at Edinburgh. In 1865 he published a volume of discourses, *Christ's Kingdom upon Earth*. His *Philosophy of History in Europe* (vol. 1, *In France and Germany*, 1874) established his reputation as a profound thinker and erudite scholar. Rewritten, part of this work appeared in 1894 as *Historical Philosophy in France and Switzerland*. *Theism and Anti-Theistic Theories* (1879–80) were the Baird Lectures for 1876 and 1877. Other works are a monograph on *Vico* (1884) and a treatise on *Socialism* (1895). See a Life by Dr Donald Macmillan (1914).

Flint Implements and Weapons of the primitive peoples of prehistoric times are commonly found in the graves or on the sites of settlements of the earlier inhabitants of almost every country in Europe. They also occur not only in the surface soil or *humus* and in peat-bogs, beds of rivers and lakes, but naturally imbedded in such superficial or quaternary deposits as the old terraces of river-valleys. These terraces, which are formed of gravel and sand deposited by the river, are the marginal remains of the old river-bed, which, having been gradually deepened by the erosion of the current, has left here and there portions of the fringes of earlier deposits on the slopes of the valley. Flint implements, however, are not universally distributed through the diluvial drifts; for, while they occur pretty generally over the south-eastern area of England, they have not been found in the northern and western areas, nor in Scotland. Similarly, on the Continent, although they are found somewhat abundantly in the north-western area of France, they do not occur in Denmark, Sweden, or Norway. The types of flint implements found in these river-gravels closely resemble those from the caves of Périgord in France, and from Kent's Cavern and other caves in England. Besides possessing similar typical forms, the

flint implements from the river-drifts and caves are in both cases found associated with the remains of animals which either are extinct or are no longer indigenous. For this reason, and also because the flint implements found in these associations are fashioned by chipping alone, they have been assigned to the earlier part of the Stone Age (q.v.). On the other hand, the flint implements, whether fashioned by chipping alone or finished by grinding and polishing, which are found in the surface soil, or in graves, or in lake-dwellings, &c., and in association with remains of the common domestic animals, are assigned to the later part of the age of stone. The types characteristic of these two divisions being thus distinguished by their form and finish, as well as by their associations, are classified by archaeologists as palæolithic and neolithic implements.

The palæolithic implements of rudely chipped flint are reducible to three classes. The first or best finished is an oval, sharp-rimmed implement, with a cutting-edge all round, the second a long, pointed implement, and the third a tongue-shaped implement. They differ from the neolithic types most markedly in this, that they do not obviously reveal their special uses and purposes, and that their conceivable uses or purposes are few in comparison with those so obviously disclosed by the more specialised forms and the more elaborate finish of the neolithic types, which a glance suffices to classify as arrow and spear heads, daggers, knives, saws, borers, scrapers, chisels, axes, &c. Most of the neolithic implements are finely shaped and carefully finished, while some varieties, such as the long thin knife-blades and the handled dagger-blades of Denmark and Sweden, which are finished by chipping only, are perfect marvels of workmanship—so skilfully executed that experienced lapidaries and scientists can only speak of the process of their manufacture as a lost art. No modern savages or barbarous tribes of the historic period have produced anything approaching to the masterpieces of pre-historic flint-working. Flint, from its conchoidal fracture, is the only kind of stone that is capable of being readily worked into a variety of shapes by flaking and chipping, and this is probably the chief reason why the palæolithic implements have been formed almost exclusively of this material. The methods of manufacture seem to have been analogous to those employed in the manufacture of gun-flints and strike-lights of flint for export (the gun-flints chiefly to Africa, and the strike-lights to the East and to Brazil) carried on at Brandon (q.v.) in Suffolk, the principal differences being that steel tools are now used instead of tools of stone and bone, and that the finer processes of surface chipping and flaking are not now practised. Detailed descriptions of the various processes of flint-working, and of the ancient and modern methods of manufacture, are given in the first part of Sir John Evans's work on the *Ancient Stone Implements, &c. of Great Britain* (1872; new ed. 1897); the finer forms of flint implements are illustrated by Madsen, *Afbildninger af Danske Oldsager* (1869), and Montelius, *Civilisation of Sweden in Heathen Times* (trans. 1889).

Flintlock. See FIREARMS.

Flint River, in Georgia, U.S., rises about 10 miles S. of Atlanta, and unites, after a southerly course of some 400 miles (of which 150 are navigable for steamboats), with the Chattahoochee, at the south-west angle of the state, to form the Appalachicola (q.v.).

Flintshire. See FLINT.

Flinty Slate is an impure quartz, assuming a slaty structure. It contains about 75 per cent. of

silica, the remainder being lime, magnesia, oxide of iron, &c. Its fracture is rather splintery than shell-like. It is more or less translucent. It passes by insensible gradations into clay-slate, with which it is often in most intimate geological connection. Lydian Stone is a variety of flinty slate.

Floating-battery, a hulk heavily armed and made as invulnerable as possible, for defending harbours or attacking marine fortresses. They were used by the French and Spaniards in 1779-83, when ten, carrying 212 large guns, were brought to bear on Gibraltar (q.v.); they had sides of great thickness, and were covered with sloping roofs, to cause shot to glance off innocuously. But General Eliott succeeded in destroying them with red-hot cannon-balls. Steam floating-batteries of iron were constructed for the war with Russia in 1854 by the British and French governments; but though they rendered good service, they were soon discarded. However, vessels of this class called Monitors were built for use by England and used successfully in the Great War. They were of light draught, had bulges on the sides to lessen danger of being sunk by torpedo. Some carried a 15-inch gun, anti-aircraft guns and armoured turrets, and steamed 7 to 10 knots. Monitors so called were first used in American Civil War by Southern and Northern forces. See NAVY.

Floating-islands are formed either by the aggregation of driftwood in the creeks and bays of tropical rivers and the deposition thereon of soil and vegetable matter, or by the detachment of portions of a river-bank or lake-shore, on which the interlacing roots of plants constitute a foundation sufficiently strong to support soil whereon herbage, and occasionally even trees, are able to grow. Such islands are sometimes seen 50 or 100 miles distant from the mouth of the large rivers of America, Asia, and Africa. Portions of the alluvial soil from river-deltas, held together by the roots of mangroves and other trees, are sometimes detached by hurricanes or typhoons and then swept out to sea; such islands have been met with in the Philippines, in the seas of the East Indies, and in the Pacific. A floating-island is mentioned by Herodotus as existing in Egypt. Others were known to Roman writers: Seneca speaks of them as being in the Vadimonian, Cutilian, and Stationian lakes in Italy; to these Pliny adds the islands floating on lakes near Cæcubum, Reate, and Modena, and two others in Asia Minor. Those on Lake Vadimona were, according to the Younger Pliny, capable of supporting sheep. Varenius, in the middle of the 17th century, cites a lake in Honduras with floating-islands. Passing over others in Prussia, Italy, and South America, we come to Great Britain, where we find it recorded that Loch Lomond long possessed a floating-island, which has now, however, disappeared or become attached to one of the stationary islands of the loch. In Ireland large masses of peat float about some of the bogs—the Bog of Allen, for instance. In England, in Derwentwater, there is an instance of an island which appears and disappears from time to time in the same spot. Perhaps the most satisfactory theory is that which attributes its rising from the bottom to the permeation of its mass by marsh-gas during hot weather, the upward motion being assisted by the growth of buoyant water-plants on its surface. The same seems to hold of those (sometimes as many as sixty) in the Lake of the Floating Islands in Yamagata, Japan, famous since the 14th century.

Between 1696 and 1829, similar islands were observed at irregular intervals, generally, however, after great droughts and violent storms, in Lake Rälång in the Swedish province of Småland. Oceanic

floating-islands sometimes perform important service in the transportation of vegetable seeds from place to place, also in the distribution of animal species, by carrying insects, land mollusca, and small mammalia, more rarely reptiles. Darwin met with islands floating on Lake Tagua-Cagua in Chile which passed from side to side of the lake and carried 'cattle and horses as passengers.' In the latter half of the 19th century the White Nile was rendered almost unnavigable owing to the accumulations of floating vegetable matter or 'sudd,' which had to be cut and removed on a very large scale in 1900-2. In some instances it gave rise to serious inundations. The vale of Kashmir contains many lakes, which frequently overflow and drown the surrounding country. This has taught the inhabitants to construct floating-gardens for the cultivation of their vegetables. The gardens are in reality portions of the marshy ground made to float artificially by cutting through the roots of the reeds and other plants about two feet below the surface. The Chinese, too, devote considerable attention to this style of horticulture, but more by way of ornamentation. Floating-gardens, or *chinampas*, also existed in Mexico before the Spanish conquest. Clavigero describes them as formed of wicker-work, the stems of water-plants, and mud, the largest sometimes having on them a tree or a hut. Both flowers and vegetables were grown on them.

Floatstone, a variety of silica, consisting of fibrous concretions of opal, aggregated so that the whole mass is sponge-like, and so light, owing to the air confined in the interstices, as to float for a while in water. It is found in a limestone of the chalk formation near Paris, in imbedded masses, or incrusting flint nodules.

Flodden, **BATTLE OF**, fought between James IV. of Scotland and an English army under the Earl of Surrey, September 9, 1513, the most grievous defeat ever Scotland suffered. King James, with 30,000 men, had taken up a strong position on Flodden Hill, one of the east and lowest spurs of the Cheviots, about 6 miles south of Coldstream, and on the morning of the 9th the Earl of Surrey, with 32,000 men, advanced from the south-east, crossed the Till by a skilful movement, and thus cut off all communication between King James and Scotland. James neglected the opportunity of attack while the English were crossing the river, but, seeing that they were aiming at taking up a strong position to the north-west of Flodden Hill, ordered his tents to be set on fire, and advanced to the attack about four o'clock in the afternoon. The Earls of Huntly and Home, who commanded the left wing of the Scottish army, charged the English right, which was led by Sir Edmund Howard, and entirely defeated it, but Home's borderers threw away the advantage of their success by commencing to pillage the baggage of both armies. On the Scottish right the clansmen under Lennox and Argyll, goaded to fury by the English archers, rushed heedless of order upon their opponents, but were routed with great slaughter and put to flight. Meantime a desperate resistance was made by the Scottish centre, where the king fought on foot among his nobles. Night fell upon them still fighting heroically, the ring still unbroken, though within it the king lay dead. The Scots held the hill during the night, but at dawn retreated with a loss of from 5000 to 12,000 men, including the flower at once of bravery and of rank. The Archbishop of St Andrews and as many as twelve earls were among the slain, and long after, indeed, there 'was not a worshipful Scots family that did not own a grave on Brankstone Moor.' The English loss amounted at most to 4000; but Surrey's victory

was so nearly a defeat that he was unable to prosecute the war with any vigour. The sixth canto of Sir Walter Scott's *Marmion* contains a splendid and fairly accurate description of the battle. See Robert White, *The Battle of Flodden* (Newcastle, 1859).

Flogging. Corporal punishment, which, in deference to public opinion, was abolished in 1881, had existed from time immemorial in the British army and navy. It was often inflicted upon slight occasion, and with barbarous severity. Thus, at the beginning of the 19th century court-martial sentences of a thousand lashes were very common for mutiny and other grave offences even in time of peace. After the Crimean campaign, however, it became usual, unless the troops were on active service, to remit the sentence of corporal punishment, which a court-martial could still legally award to the extent of fifty lashes. The Act of 1879 went further in this direction, and made it illegal to inflict corporal punishment, except on active service, for offences punishable by death, and limited the amount to twenty-five lashes. Finally this provision was repealed by the Army Act of 1881, and summary punishment provided as a substitute. This consists of hard labour, personal restraint by being kept in fetters, and, in its severest form, of being attached to a fixed object in such a manner as to be kept in a fixed position for two hours at a time. Boys were left punishable by birching or caning, but in 1906 birching was tentatively suspended, caning only being allowed. Soldiers are still liable to corporal punishment, limited to twenty-five lashes, when in prison, for an offence against the prison rules, and for highway robbery with violence.—In European armies recruited by compulsion from all classes of society, flogging is not a military punishment.

As a punishment for misdemeanours at common law whipping has never been formally abolished, though it has never been exercised in modern times except under the provisions of some special statute. Local police acts give power to whip juvenile offenders; and by a statute of 1863 (which does not apply to Scotland) flogging was made a competent punishment for certain forms of robbery with violence, as garrotting. Sir James Stephen says of this statute that it is 'an act so capriciously worded, that if a man beat a woman about the head with intent to rob her he may be flogged, but not if his object is to ravish or murder her.'

At common law the instrument to be used for whipping and the number of strokes are left to the discretion of the person who inflicts the punishment. When sentence of whipping is pronounced by justices, the order must specify the instrument and the number of strokes. If the offender is under fourteen years of age, the number of strokes must not exceed twelve, and the instrument must be a birch rod. Under the Act of 1863 a court may direct a person convicted of robbery to be privately flogged—not more than three times. If the offender is under sixteen, the number of strokes at each whipping must not be more than twenty-five; and, no matter what the offender's age, the number must not be more than fifty. In Scotland no offender above sixteen years can be whipped for theft or for any crime committed against person or property (Act 25 Vict. chap. 18, sect. 2).

Flood, **HENRY**, Irish orator, was born in 1732, and educated at Trinity College, Dublin, and at Christ Church, Oxford. Elected to the Irish parliament as member for Kilkenny in 1759, and for Callan in 1761, he soon became a leader in the popular party. His oratory was vigorous and impressive, but was marked by all the offensive personalities of his time. In 1769 he was unfortunate enough to

kill an electioneering opponent in a duel, and was brought to trial, but acquitted. In 1775 he took office as vice-treasurer of Ireland, but was removed in 1781 on account of his strong nationalist sympathies. Disliking Grattan's Irish Bill of Right as not going far enough, Flood strove without success to carry a more sweeping measure, and became involved in a bitter quarrel with his former friend, which would have resulted in a duel but for the timely intervention of the authorities. In 1783 he was returned for Winchester to the English House of Commons, and two years later for Seaford, but he failed to make as great a mark at Westminster as in Dublin. He died at Farnley, his seat near Kilkenny, December 2, 1791, leaving £5000 a year to Trinity College, Dublin. See his *Life and Correspondence*, edited by W. Flood (Lond. 1838).

Floods and Inundations are caused by excessive rains, giving rise to an overflow of the rivers; by the bursting of the banks of rivers, lakes, and reservoirs; by the sudden melting of ice and snow; and by irruptions of the sea, produced by high tides, wind-storms driving the sea-water inland, earthquakes, volcanic outbreaks, and the bursting of sea banks. The felling of forest trees throughout extensive tracts of mountainous country also tends to make the rivers which have their origin there swell rapidly after a heavy rainfall; good and complete drainage of land has the same tendency. For the Noachian flood, see DELUGE. The subjoined list embraces some of the most disastrous floods and inundations of which we have record.

- 684 A.D. Japan; 780 sq. m. of Isle of Shikoku covered by sea.
- 968. Persian Gulf; many cities destroyed, and new islands formed by irruption of sea.
- 1014. Many English seaports destroyed by sea
- 1098 or 1100. East of Kent inundated; Goodwin Sands formed.
- 1100 or 1108. Flanders inundated.
- 1161 or 1165. Sicily; irruption of sea; thousands drowned.
- 1170. Holland and Friesland; great flood.
- 1178. Holland; Zuyder Zee much enlarged.
- 1219. Nordland, Norway; lake burst; 36,000 people perished.
- 1228. Friesland; invasion of sea; 100,000 people drowned.
- 1277. Friesland; the Dollart formed.
- 1286-87. Holland on both sides of Zuyder Zee inundated in consequence of a storm.
- 1396. Holland; islands of Texel, Vlieland, and Wieringen separated from mainland, and Marsdiep, the channel between Texel and North Holland, formed.
- 1421 or 1446. Holland; 72 villages inundated, of which 20 permanently, about 100,000 persons drowned, Biebosch formed east of Dordrecht, and this town separated from mainland.
- 1521. Holland; 100,000 lives lost by an inundation.
- 1570. Holland; storm drove in the sea, destroying numerous villages and 20,000 people in Friesland.
- 1617. Catalonia, Spain; 15,000 perished in floods.
- 1629. Mexico (city) inundated.
- 1642. China, at Kaifong; 300,000 drowned.
- 1646. Holland and Friesland inundated; loss of life, 110,000.
- 1726. Floods and inundations all over Europe.
- 1745. Peru; Callao destroyed by irruption of sea caused by earthquakes.
- 1767. England; irruption of sea on east coast.
- 1782. Formosa; west side of island submerged, and Taiwan destroyed.
- 1787-88. Northern India; 15,000 lives lost by floods.
- 1791. Cuba; floods from excessive rain; 3000 drowned.
- 1811. Hungary; 24 villages swept away by overflow of Danube
- 1813. Austria, Hungary, Poland, and Prussian Silesia; floods caused by rains; 4000 perished in Poland, 6000 in Silesia.
- 1824. St Petersburg and Cronstadt; 10,000 lives lost from overflow of Neva.
- 1825. Denmark; sea broke through from North Sea to Limfjord, making northern Jutland an island; one-third of Friesland submerged by rising of sea and rivers.
- 1839. Morayshire.
- 1840. France; overflow of Saône and Rhone swept away many villages and inundated Lyons, Avignon, Nîmes, Marseilles, &c.
- 1851. Northern China; Yellow River burst its banks, and made a new outlet into Gulf of Pechili.
- 1852. Floods throughout Europe from Belgium to Switzerland.
- 1856. South of France; floods did damage to extent of \$5,000,000.
- 1868. Peru; Arica and Iquique nearly destroyed by earthquake waves
- 1874. United States; Mill River valley (Massachusetts) inun-

- dated by bursting of a dam; 144 drowned. Also floods in western Pennsylvania; 230 drowned.
 - 1875. Disastrous floods throughout central Europe, in United States, Burma, India, and West Indies.
 - 1876. China; floods in northern provinces; in Bengal 200 000 persons perished from inundation of a sea wave.
 - 1883. Java and Sumatra; volcanic wave (see KRAKATOA).
 - 1887. China; Hoang-ho flooded in Ho-nan; millions drowned.
 - 1889. Johnstown, U.S.; reservoir burst; 2209 lives lost.
 - 1891. Consuegra, Spain; 1200 lives lost.
 - 1893. Queensland; great destruction of property.
 - 1895. Japan; volcanic wave.
 - 1903. Mississippi Valley.
 - 1913. Ohio basin: Dayton suffered most in this appalling disaster.
 - 1917. North China.
 - 1923. Lake of Gleno, near Lago d'Iseo.
 - 1924. North China, India.
 - 1926. Holland, Belgium, &c.
- Some parts of the world are periodically submerged, such as extensive tracts in Siam, Cochun-China, and Annam, &c.

Floor. The floors of the upper stories of ordinary houses are nearly always constructed of wood, but in many large public and other buildings all the floors are fireproof, some of these, for example, being formed of a series of flat brick arches between iron girders. Basement floors and others near the level of the ground are often laid with flagstones, tiles, or cement, but many of these are also of wood. According to the nature of their construction, wooden floors are of three kinds—viz. *single*, *double*, and *framed floors*. When the span between the walls does not exceed 15 feet, a single-joisted floor is sufficiently strong. Sometimes it is even adopted

Section of a Single Floor :

a, b, c, d, joists; s, strutting; f, flooring-boards, p, sound or deafening boarding; y, pugging or deafening; m, ceiling-lath; n, plaster.

for a 20-feet span. The annexed figure shows the section of a floor of this kind. The joists vary in section; but 9 inches by 3 inches for moderate, and 11 inches by 3 inches for larger spans are common sizes, and they should not be more than 16 inches apart from centre to centre. They are laid at the ends on wall-plates of wood. If their lengths much exceed 10 feet, joists should be strutted in order to stiffen them and keep them in position. This can either be done by herring-bone strutting, shown in the figure, which is the better way, or by key strutting with solid pieces of wood morticed through the joists with small tenons. The latter method is called 'dwanging' in Scotland, and the rows of dwangs or keys are usually nailed between the joists. The lines of struts or keys should be at intervals of about 7 feet. Flooring-boards are nailed on the top of the joists, and Laths (q.v.) on the bottom of them to support the plaster of the ceiling of the room below. To prevent the passage of sound to and from rooms between which the floor forms the horizontal partition, what is called 'pugging,' or (in Scotland) 'deafening,' is required. It consists of coarse plaster, &c., laid on rough boards or laths supported on fillets nailed to the sides of the joists (see BUILDING).

Double-joisted floors are constructed by laying strong timbers, called *binders* or *binding-joists*, from wall to wall, at a distance of about 6 feet apart; and a double set of joists, one above for the flooring-boards, and one below for the ceiling, are laid across these, and notched down upon them. Of these the upper ones are called *bridging-joists*, as they bridge over the interval between the larger binding-joists. A *bay* is the general name for the space between binders; if between a binder and wall, it is called a *tail bay*.

The *framed floor* is one degree more complex than the double-joisted. Binding and bridging joists are used in the framed floor, but the binding-joists cease to be the primary support, as for this purpose strong balks of timber, called *girders*, are used. They are laid across, at distances of from 8 to 10 feet, and the binding-joists are framed into them by a *tusk-tenon* joint. The bridging-joists are notched to these in the same manner as for double-joisted floors. When the span is too great for a wood-girder, either a girder wholly of iron is used, or one formed of a wrought-iron plate with wood on each side, all three pieces being bolted together. The latter is called in Scotland a 'sandwich beam.'

Flooring-boards are jointed in several ways. Perhaps the most common is the *grooved and tongued* joint, in which a tongue worked on one edge of a board fits into a groove in the next board. In a *ploughed and tongued* joint each board is grooved on both sides, and a separate tongue of wood or iron inserted. A *rebated* joint means that each board is checked along the edges, and these fit into reverse checks on the two adjoining boards. In a *dowelled* joint the edges of the boards are square and unbroken, and small oak pins or dowels are inserted at intervals in holes bored along the edges. Flooring-boards should not be more than 6 inches broad, and in the best floors they do not exceed 3 or 4 inches. They are from 1 inch to 1½ inch thick—very commonly 1½ inch. On the continent of Europe polished oak floors are very common. In America, and occasionally in Britain, two thicknesses of flooring-boards are used in floors of a superior description.

For fireproof flooring, see FIRE; and for special kinds of ornamental and other floors, see ASPHALT, CONCRETE, MOSAIC, PARQUETRY, and TILES.

Floorcloth. There are several kinds of floorcloth. Formerly the name was confined to painted canvas, which is now called oilcloth; but the more recently introduced linoleum and other fabrics in which ground cork bulks largely are now extensively used for covering floors.

Oilcloth.—The basis of oilcloth is a coarse canvas generally made of jute, but it is stronger when made of flax tow. It is woven into pieces often as long as 150 yards and as wide as 8 yards. The first step is to fix a piece of this, say 75 feet in length by 24 feet in width, upon an upright frame provided with screws by means of which the canvas can be uniformly stretched. Stages or platforms are placed at convenient heights to enable the workmen to cover the canvas. Before paint is applied the canvas receives a coating of size, the chief object of which is to prevent injury to the cloth by acid products arising from the oxidation of the linseed-oil with which the paint is made up. When the size is thoroughly dry and pumiced, a layer or coating of paint is put on with steel trowels like those used by plasterers. Yellow ochre is much used for this thick coating, which if unaided by artificial heat sometimes takes fourteen days to dry. A second coat is applied in the same manner to finish the back, but the face receives five or six trowel coats, the surface being once or twice pumiced between the coats. The wearing surface receives a coat of paint with a brush if some other colour than that of the last trowel coat is wanted for the ground shade. In the case of cheap oilcloths, the coats of paint, instead of being applied by trowels, are put on by a roller machine. A man keeps pouring the prepared paint out of a bucket on the moving canvas, and a long blunt knife-blade, almost touching its surface, regulates the thickness of the coat of paint. When made by this method, the oilcloth receives nine coats.

In printing, wood blocks are chiefly used, a separate one being required for each colour of the pattern. These are about 18 inches square, and the face is commonly made of pear-wood, with a pattern cut out by steel tools. There is an ingenious way of producing patterns on wood blocks by heated iron punches. Sometimes the raised portions of these printing-blocks consist of type-metal or brass. Fig. 4, A, B, C, D, of the article CALICO-PRINTING will give an idea of how the impressions from several blocks complete a pattern. Beside the printers there is a table upon which are placed the colour-pads. Another table, padded with felt or flannel, supports the floorcloth, each pattern block, charged with colour, being applied by means of a small screw-press. A machine is in use for printing floorcloth which to a certain extent imitates hand-printing. The blocks which form the pattern are depressed by cams carried on shafts. Roller machines are not applicable to this kind of printing, because the paint would 'run' on a revolving surface. The durability of oilcloth depends very much on the length of time given for the paint to harden, and also upon its quality.

Linoleum.—The floorcloth called by this name suits the purpose for which it is made admirably, being lasting, comfortable, and noiseless when trod upon. Its wearing face consists chiefly of pulverised cork and oxidised linseed-oil, with smaller quantities of common and kauri resin, all well mixed together, and made to adhere to canvas backed with size and pigment.

The chief operations in the manufacture of linoleum are based upon processes patented by F. Walton in 1860 (specification No. 209) and in 1863 (specifications No. 1037 and 3210).

Of these the more important are the preparation of the cork, the oxidising of the oil, the formation of the mixture of all the ingredients for the coating, and the application of this to the surface of the canvas. Pulverised cork, of which linoleum most largely consists, is obtained from waste cork-cuttings. These are exposed to the action of a series of toothed steel discs revolving on a shaft and working against steel plates, the ends of which have also teeth like those of a saw. By this machine the cork is reduced to the size of peas. It is afterwards ground with millstones.

The oxidised linseed-oil is produced by diffusing or 'flooding' the boiled oil in thin films upon the surface of long pieces of calico or scrim, placed in an upright position. This is repeated daily till the successive films of oil reach half an inch in thickness. It takes six or eight weeks to effect this, and the scrim with its many films is then called a skin. Owing to the injurious action upon vegetable fibre of the vapours given off during the oxidation of the oil the scrim becomes completely rotten. Even mineral substances are attacked by these vapours. The gain in weight shows that a large quantity of oxygen is absorbed by the boiled oil, and that a good supply of air in the oxidising buildings is therefore necessary. After being cut into small pieces the skins are ground by means of grinding-rollers. Care must be taken not to heap up the pulverised material, as in bulk it is very liable to char or ignite by the rapid oxidation of such particles as have not undergone this change previous to grinding.

A mixture is now made consisting of from 4 to 8 cwt. of the oxidised oil to 1 cwt. common resin and 1 cwt. kauri resin, the mixing operation being conducted in a pan with an outer jacket or casing containing steam. The pan has an air-tight lid, and at a valve at the bottom and inside there are stirrers. Resin is first put in and melted, the oil and kauri being separately added. As soon as the mixture is warmed the steam is shut off, the oxidation of

the materials keeping up a sufficient heat till the charge becomes homogeneous. The valve at the bottom of the pan is then opened, and the mixture, now called cement, passes down between grinding-rollers. The cement is next cooled, but before mixing it with ground cork it is again heated to at least 120° F. The proportions of these two ingredients are about equal, but sometimes the cork is rather in excess of the cement. The colouring materials (ochre and oxide of iron) are either added with the cork or previously to the cement.

There is still another mixing-machine—the most important of all. Here the material is fed by a hopper into a cylinder in which both fixed and revolving knives are placed. It has a steam jacket. When the linoleum mixture leaves this machine, the cork and cement are so thoroughly mixed that they are scarcely distinguishable by the naked eye. The next operation is to pass the mixed material between two rollers, one of which is steam heated, and the other kept cool by a current of cold water. Here it is formed into a sheet, which is then broken up by a similar arrangement of rollers, one of them being studded with points for the purpose of breaking up the linoleum material into small pellets. Finally the mixture is spread over and pressed into the canvas by a pair of rollers of chilled cast-iron heated by steam to a high temperature. The canvas afterwards receives a backing of size and pigment, and then the linoleum is finished if it is to be left plain. When a pattern is required it is printed in the same way as upon oilcloth. A mosaic linoleum, in which the pattern is made of cut pieces of coloured material fixed on a thin backing, was patented in 1882 by F. Walton. By the improved method perfected by the inventor, the pattern extends quite through the material, and shows exactly the same on both sides. The work is done automatically by a machine which mixes and manipulates the ingredients, rolls the material into sheets of various colours, cuts these sheets into pieces of the desired shapes, arranges them into patterns with unfailing accuracy, and finally rolls and solidifies the whole into a compact sheet with the required pattern.

Kamptulcon, which is made of ground cork and india-rubber, was introduced earlier than linoleum, but its manufacture has almost ceased.

Cork Carpet, a floorcloth manufactured since the middle of the 19th century, is made of cork bound with oxidised linseed-oil, but differs from linoleum in having the particles of cork larger and purer in colour, as no pigment is mixed with it. It has a canvas backing, and is the warmest kind of floorcloth.

Flora, an ancient Italian deity, the Roman goddess of flowers and vegetable productiveness, also of exuberant youthful vitality. At Rome she had two temples, one on the Quirinal, the other near the Circus Maximus. On the occasion of her festival (*Floralia*), held in the end of April, the dwellings were decked with flowers, whilst feasting, with dance and song, prevailed everywhere. Flora was represented as a flower-crowned maiden in the full bloom of maidenly beauty.—*Flora* is used botanically to designate the collective plants or vegetable species of a region, country, or district, or to any work containing a descriptive enumeration of these.—*Flora* is also the name of one of the minor Planets (q.v.).

Florence (Ital. *Firenze*), a city of Italy, capital of the former duchy of Tuscany, is situated in the valley of the Arno. It is about 150 feet above the level of the sea, 150 miles NW. of Rome, 50 E. of Leghorn. The population—100,000 by the 14th century—was 167,000 in 1871, and 253,565 (communal) in 1921. The Arno, spanned by four fine old bridges, divides the city into two unequal parts, the chief on the northern bank. Beyond the line of the ancient walls are thickly peopled suburbs, and a lovely, fertile, and salubrious neighbourhood, encircled by sloping hills, and studded with picturesque villas and fruitful vineyards and gardens. Florence and its environs, viewed from the heights of Fiesole, appear but one vast city. The influx of population consequent on the establishment here, in 1864-71, of the seat of the Italian government, necessitated a considerable extension of the city. Save on the left side of the Arno (*Oltre' Arno*), the ancient walls (13th to 14th century) were razed; but several of the old towers pertaining to the various gates are retained, and constitute an interesting historical feature of modern Florence and a useful topographical indication of the former limits of the city. Amongst modern improvements none ranks higher than the magnificent carriage-way known as the Viale dei Colli. It ascends from the Porta San Niccolò to the historic church and cemetery of San Miniato, and gradually slopes down to the Porta Romana. From the highest level of the drive, the Piazzale Michelangelo, the panorama of Florence, the Arno, with the surrounding hills and distant Apennines, is quite unique for beauty and variety of scenery. Fine new streets or quays (known as the *Lung' Arno*), which stretch along the Arno, also add much attraction to the town, and the hygienic (though not the artistic) conditions of Florence have been greatly improved by the laying out of wide avenues or *Viali* on the site of the old walls, by the opening of spacious squares and the erection of extensive new market-halls. The picturesque, if unsavoury, quarter around the Mercato Vecchio (the old Florentine *Centro*) has, since 1889, given place to the unsightly modern Piazza Vittorio Emanuele II. Notwithstanding a

Florence—the Cathedral and the Palazzo Vecchio—from the Palazzo Pitti.

rather capricious climate, Florence, with its teeming artistic treasures, its scenic attractions, and its literary and historical associations, is a favourite place of residence for foreigners and of pilgrimage for countless tourists.

The massive and austere forms of Florentine architecture impart an air of gloomy grandeur to

the streets, for the most part regular and well kept. The chief building in the city is the Duomo, or Cathedral (*Santa Maria del Fiore*), the foundations of which were laid in 1298; while in 1887 the completed façade (designed by Emilio de Fabris) was uncovered in the presence of the Italian sovereigns. The Florentines having ambitiously resolved on erecting a monument which for architectural splendour and proportions should outvie all preceding structures, the honour of preparing the design was entrusted to Arnolfo di Cambio. Later, Giotto superintended the works; and many eminent architects were employed before this splendid edifice was completed. Brunelleschi conceived and erected the grand dome, which served as model for that of St Peter's. The church contains sculptures by Ghiberti, Luca della Robbia, Michelangelo, Sansovino, Bandinelli, and other famous artists. At the side of the cathedral rises the beautiful Campanile (q.v.) of Giotto, detached, according to the custom of the times. In front is the Baptistery of San Giovanni (rebuilt *circa* 1200), in form an octagon, supporting a cupola and lantern. All three edifices are entirely coated with a varied mosaic of black and white marble. Three bronze gates in basso-relievo are a great additional adornment of the Baptistery; the two by Ghiberti (q.v.) were called by Michelangelo the Gates of Paradise. The church of the Santa Croce, the Pantheon of Florence (begun in 1294—architect, Arnolfo), contains, among others, the tombs of Michelangelo and Alfieri, and monuments to Galileo, Dante, Macchiavelli. The church of San Lorenzo was consecrated as early as 393 by St Ambrose, and rebuilt by Brunelleschi in 1425, by command of the Medici. The façade still remains naked and unfinished. San Lorenzo contains a monumental memorial of Cosimo il Vecchio, bearing inscribed the title *Pater Patriæ*. In the *Sagrestia Nuova*, or New Sacristy, added by Michelangelo, are that master's two famous monuments to Giuliano and Lorenzo de' Medici. The Medicean chapel, gorgeous with the rarest marbles and most costly stones, agate, lapis lazuli, chalcidony, &c., stands behind the choir, and contains the tombs of the Medici family. Annexed to the church of San Lorenzo is the Laurentian Library (also designed by Michelangelo), with its inexhaustible store of rare MSS. The beautiful church of Santa Maria Novella (1278–1350), formerly Dominican, has fine cloisters and famous frescoes by Orcagna, Filippino Lippi, and Ghirlandajo. The church of San Marco dates from 1436; adjoining it is the former monastery of San Marco, now secularised as the Museo Fiorentino di San Marco. Fra Angelico, Savonarola, and Fra Bartolommeo were inmates, and it is still adorned with the famous frescoes of Fra Angelico. Other outstanding old churches are the Annunziata, the Badia, Santa Maria del Carmine, San Miniato al Monte, Or San Michele, Santo Spirito, and Santa Trinità.

Amongst the numerous palaces *Il Bargello*, long a prison, but now restored and opened as a national museum (1865), is one of the most ancient, and was (1266–1502) the abode of the chief magistrate, the Podestà. The museum contains such masterpieces as Donatello's *St George* and *David*, and a remarkable portrait of young Dante in a fresco ascribed to Giotto. The Palazzo Vecchio, the seat of the republican government from its establishment till its abolition in 1530, is an imposing mass of building, surmounted by a lofty tower 260 feet high, the great bell of which used to warn the citizens of danger or summon them to defence. Beside the palace (now the town-hall) is the Piazza della Signoria, with some fine statues, and a noble arcade, the Loggia dei Lanzi, under the porticoes of which are magnificent groups of sculpture. In one of the

halls of the Palazzo Vecchio there now stands a colossal statue of Savonarola a few paces distant from the spot where the reformer perished at the stake. The Palazzo degli Uffizi is a handsome building adjoining the Palazzo Vecchio, founded by Cosimo I., and erected by Vasari (1560–74). Here are deposited the state archives of Tuscany, also the Magliabechi Library, now united with that of the Pitti Palace to form a Biblioteca Nazionale of 500,000 volumes and 20,000 MSS. On the second floor is the famous *Galleria degli Uffizi*, extraordinarily rich in paintings, engravings, sculpture, bronzes, coins, gems, and mosaics. A splendid apartment, known as the Tribuna, contains the rarest treasures of the collection. The Palazzo Pitti, from 1550 the grand-ducal residence, given to the nation by the king in 1919, also boasts of a superb gallery of paintings. Behind it are the beautiful Boboli Gardens. The Pitti and Uffizi palaces are connected by a covered corridor (built 1564), about a mile long, which crosses the Arno on top of the goldsmiths' shops which have flanked the famous Ponte Vecchio since the 14th century. The Palazzo Riccardi (once Medici) is the prefect's seat. The Palazzo Strozzi, a fine type of Tuscan architecture, and the Palazzo Corsini (with an art collection), are among the many notable private palaces. In the NW. lies the Cascine, a wooded public park. In the old Protestant cemetery are buried Walter Savage Landor, Mrs E. B. Browning, and Arthur Clough.

Although Florence has no university, the Istituto di Studi Superiori has adopted the ordinary university curriculum, and confers various degrees. It owes much of its success to the eminent historian, Professor Pasquale Villari. The School of Social Science was founded by the Marchese Alfieri di Sostegno. The hospital of Santa Maria Nuova contains an ancient college of medicine and surgery. The Confraternity of the Misericordia, who built the beautiful Loggia, called the Bigallo (*circa* 1358), still pursue their charitable duties in their picturesque black robes and face-concealing hoods. The Academy of the Fine Arts (with Michelangelo's great *David*, and many works of the early Tuscan masters) and the Museum of Natural History are of inestimable educational value. Florence has no fewer than four important libraries (National, Laurentian, Riccardian, and Marcellan); several museums (National, Natural History, Archaeological, Opera del Duomo, &c.); and a Conservatorium of Music. The Accademia della Crusca (see ACADEMY) is entrusted with the care of sifting and preserving uncorrupted the Italian language. The Spedale degli Innocenti (founding hospital) was built early in the 15th century. Florence is the see of an archbishop, the seat of a prefecture and of numerous provincial courts, headquarters of an army corps, and capital of a like-named province (area, 2260 sq. m.; pop. 1,000,000). Its railway communications are ample. Save catering for tourists, Florence has no big industries. The fabrication of silks and woollens (active in the Middle Ages) has declined. Strawplaiting (hats, fans, &c.) is sold in the 16th-century Mercato Nuovo. Jewelry, majolica, glazed pottery, *pietra dura* work, and *objets d'art* of local manufacture, are displayed everywhere. The Florentines are famous for their caustic wit and natural gifts of eloquence, as well as for their shrewd thriftiness and unflagging labour.

History.—The city of Florence sprang originally from Fiesole (q.v.), at the foot of which it lies extended. The inconvenient and hilly site of the Etruscan Fiesole, perched on the crest of an irregular height, rendered that town so difficult of access to the traders who resorted to its market-places with their varied merchandise that it was at length decreed they should assemble at the base of the hill,

in the fertile plain traversed by the Arno. The few rough shelters erected for the accommodation of these traders may be considered the original nucleus of the important and splendid city of Florence. It would seem that as early as the time of Sulla there was a Roman colony here; another was established after the death of Julius Cæsar, and it soon became a thriving town. The *Florentini* are mentioned by Tacitus, 16 A.D., as sending delegates to Rome, but it was not till the time of Charlemagne that Florence began to rise out of obscurity. It was now governed by a political head with the title of Duke, assisted by various subordinate officers, who were elected by the united suffrages of the duke and citizens. In the 11th century Florence and a great part of Tuscany were bequeathed to Pope Gregory VII. by his friend and partisan the Countess Matilda, who inherited from her mother, the Countess Beatrix, her jurisdiction over the city. Under the protection of Rome, Florence speedily adopted the forms and institutions of a free city; and the republican spirit which then arose amongst the people imparted an impulse to national life, and awoke a spirit of patriotism and enterprise. As early as the 11th century the Florentines were European traders and the possessors of commercial depôts in the seaports and cities of France and England, and their skill as workers in gold (see *FLORIN*) and jewels had grown famous. The 'arti' or trade-guilds were of great importance. In proportion as papal preponderance increased in Florence, that of the empire sank; and in 1113 the citizen forces routed the troops and slew the delegate of the emperor at Monte Cascioli, near Florence. During the bitter wars between pope and emperor which raged throughout Italy, Florence and all Tuscany seemed to have been saved from the feuds of Guelphs and Ghibellines—the former adherents of the papacy, the latter of the empire. But in 1215 Florence became involved in the great party struggle, owing to a private feud breaking out between two noble families, chiefs of the contending principals. A Guelph noble, Buondelmonti, mortally incensed the Ghibelline family of the Amidei, by breaking off his alliance with a daughter of their house, and contracting marriage with a member of a Guelph family. To avenge this insult the Amidei appealed to their powerful kinsmen, the Uberti, and in fact to all the Ghibelline party of Florence. Buondelmonti was stabbed to death as he crossed the Ponte Vecchio, and was speedily avenged by the Guelphs in the blood of his enemies. Thus for thirty-three years was Florence distracted by the deeds of bloodshed and violence of these two rival factions, who assumed the names and adopted the respective causes of Guelphs and Ghibellines. See *GUELPH AND Ghibelline*.

In 1250 the animosity of these parties seemed somewhat blunted, and public attention was directed to wise internal reforms. Twelve magistrates, or anziani, were appointed in place of the consuls, each of the six sections into which the city was divided being entrusted to two of these magistrates, whose tenure of office was annual. To avoid all local dissensions, two other magistrates, strangers by birth, were elected: the one, invested with supreme authority in civil and criminal cases, was called the podestà; the other, with the title of captain of the people, had the chief command of the militia, in which were enrolled all the youth of the state, who were bound, at the call of this magistrate, to join their company fully equipped for fight: twenty companies defended the town, ninety-six the country. After the death of the Emperor Frederick II., the great protector of the Ghibellines, the Guelph or papal party gradually rose in power in Florence, and during ten years of their predominance the city increased in grandeur and

prosperity, until it stood not only the first in Tuscany, but one of the first of all Italy. Its forces successively humbled the adjoining towns of Siena, Arezzo, Pisa, and Pistoia, and in 1254 captured Volterra. In 1260 the standard of civil war was again raised by the Ghibellines of Florence, who, in league with Manfred of Naples, attacked the Guelphs, and cut their forces to pieces in the sanguinary battle of Monte Aperto. The conquerors entered Florence forthwith, and in the name of Manfred abolished all trace of the popular institutions, establishing an exclusively aristocratic executive; they even strongly advocated the entire destruction of the city, the hotbed of Guelphism. This barbarous scheme was indignantly repudiated by their own famous leader, Farinata degli Uberti, immortalised by Dante for his patriotism. He even declared his intention of heading the Guelphs, were such a sacrilege perpetrated by his own party.

Pope Urban IV., French by birth, summoned against the Ghibelline Manfred a French army, led by Charles of Valois, to whom he offered the prospective kingdom of the Two Sicilies. Manfred was defeated and slain in the famous battle of Benevento, and Guelph ascendancy was restored anew throughout Italy and Florence. Charles restored to the Florentines their internal institutions, and received their allegiance for ten years in 1266. In 1282 a new executive power, the *Priori*, was established in Florence by the City Guilds; and in 1293, by consent of the *Priori*, a higher chief than their own order was elected, the *Gonfaloniere* of Justice. In 1300 Dante became one of the *Priori*, and the former feud was recommenced with new vigour between two factions, who now bore the names of Bianchi (Whites) and Neri (Blacks). Their dissensions were, however, interrupted by the appearance of Charles of Valois, sent by Boniface VIII. to restore tranquillity, in 1301. Charles espoused the part of the Guelphs or Neri, and sanctioned every outrage on the Bianchi, who were plundered and murdered barbarously, the survivors being exiled and beggared; among these were Dante and Petracco dell' Ancisa, the father of Petrarch. In 1306 Pistoia was besieged and taken by famine with great barbarity. In 1315 the Florentines met with a severe check from the Ghibellines of Pisa, under the command of Uguccone della Faggiuola; and in 1325 they were completely defeated by Uguccone's successor in command, the valiant Castruccio Castracani, in the battle of Altopascio. Florence, weakened by long dissensions, and alarmed by Castruccio's threat of marching on the city, appealed to the king of Naples for aid. They received joyfully an officer of the king, entitled the Duke of Athens, sent as viceroy; and, such was the public demoralisation of the moment, they proclaimed him dictator of the republic, unanimously suppressing the offices of *priori* and *gonfaloniere*. The intrigues of this ignoble schemer to overturn the republic being discovered, he was ignominiously expelled by a general popular rising, and barely escaped with his life. An attempt to admit a proportion of the nobles into the government signally failed at this time, and only led to renewed animosity between them and the citizens. This was the last effort of the nobles to secure power.

A terrible pest ravaged Florence in 1348, sweeping off 100,000 inhabitants (see *BLACK DEATH*, *BOCCACCIO*). The chief power about this time seems to have been alternately wielded by the democratic families, the Alberti and the Ricci, and by their patrician rivals, the Albizzi, who for the space of fifty-three years guided the republic in the path of progress. In 1406 the ancient and illustrious republic of Pisa (q.v.) fell under the sway of Florence, after a heroic resistance. From 1434 the history of Florence is

intimately bound up with the House of Medici, distinguished for their patronage of art and literature—especially Lorenzo the Magnificent (see MEDICI). The Medici were repeatedly banished from Florence for aiming at sovereign power; and to their intrigues Florence owes her final loss of republican rights and institutions. The extraordinary labours of Savonarola (q.v.), his trial and execution at the stake, belong to the last decade of the 15th century. Pope Clement VII., of the House of Medici, formed a league with the Emperor Charles V., by which the liberties of Florence were to be extinguished and the sovereign power to be invested in Alessandro de' Medici. In September 1529 an army of imperialists, under the Duke of Orange, entered Tuscany; and on the 8th August 1530 the siege of Florence terminated, after a defence of unexampled devotion and bravery.

Thus expired the proud republic of Florence. From this period Florence loses her distinctive history, and is only known as capital of the grand-duchy of Tuscany, Pope Pius V. having conferred on Cosimo de' Medici the grand-ducal dignity. On the extinction of the Medici in 1737, Tuscany fell to the Duke of Lorraine; and in 1803 was given by Napoleon to his sister Elise. Florence continued to be the seat of the grand-ducal court until 1859; and after the constitution of the united kingdom of Italy the city held the position of provisional capital of the country from 1864 until 1871. The departure of the court gave for a time an inevitable check to the prosperity of the town. In 1895 the city suffered from earthquakes, but the public buildings were hardly injured. The splendour of Florence as a republic may be judged from the facts that her capitalists were so enormously wealthy that they supplied the chief sovereigns of Europe with funds; her manufactures of wool, silk, and gold brocade were exported throughout the world; and she possessed great commercial establishments all over Europe.

In art Florence holds a unique place: the Florentine school of painting, from Cimabue to Andrea del Sarto, is admittedly the most important in Italy. In Italian literature the position of Florence is scarcely less conspicuous. In the Renaissance (q.v.) she played a leading rôle. Among the most eminent sons of Florence or of Florentines are Dante, Boccaccio, and Petrarch; Bartolommeo, Botticelli, Bronzino, Cimabue, the Gaddis, Giotto, Orcagna, Masaccio, Ghirlandajo, Leonardo da Vinci, the Lippis, Andrea del Sarto; Carlo Dolci; the sculptors Della Robbia, Donatello, Ghiberti, Bandinelli, Cellini, Verrochio, Michelangelo; the architects Arnolfo di Cambio, Brunelleschi; the musicians Lully and Cherubini; Machiavelli, Brunetto Latini, Galileo, and the historians Villani, Guicciardini; the navigator Amerigo Vespucci; the Medici, &c. Through the works of its writers the Florentine Italian, not that of Rome, became classical.

See the articles BOCCACCIO, DANTE, ITALY, MACHIAVELLI, MEDICI, MICHELANGELO, PAINTING, SCULPTURE, &c., and works there quoted; historical works by Capponi (1875), Perrans (1877-90; trans. 1893), Davidsohn (1896 *et seq.*), and especially Villari (trans. 1895); books on the city by Yriarte (1880), Grant Allen (1897), Hare (new ed. 1901), E. G. Gardner (1900), Hyett (1903), H. Vaughan (1911); E. V. Lucas, *A Wanderer in Florence* (1912); Ruskin's *Mornings in Florence*; and George Eliot's *Romola*.

Florence of Worcester, a chronicler who was a monk in the monastery of Worcester and died in 1118. His *Chronicon*, which comes down to 1116, in its earliest part is scarce more than a compilation from the Saxon Chronicle and Marianus Scotus; but about the year 1030 it becomes of greater value as an independent authority. It was edited by Benjamin Thorpe for the English

Historical Society (2 vols. 1848), and translated by Forester (1847) and Stevenson (1853).

Flores, the name of two islands. (1) One of the Sunda islands in the East Indies, lying due south from Celebes. It is of an oblong shape, with an area of 6000 sq. m., is heavily timbered, and mountainous in the interior, forming, in fact, an eastward continuation of the Sumatra-Java volcanic girdle. It belongs to Holland. The western half, called Mangarai, is administratively attached to Celebes; the eastern half, known as Eudeh, to Timor. Trade, principally in tortoiseshell, cinnamon, sandalwood, and edible birds'-nests, is almost exclusively in the hands of Bugis (see BONI).—(2) An island of the Azores (q.v.).—There is also an Uruguayan department of the name; pop. 25,000.

Flores, JUAN JOSÉ, first president of Ecuador, was born in Venezuela in 1800, and fought with distinction through the long war of independence. He was elected president of the new republic in 1830, resigning in 1835, and was re-elected in 1839 and 1843. He died in 1864.

Floret, a term applied to the flowers of any small and closely-crowded inflorescence which resembles at first sight a single flower—e.g. composites, teasels, scabiouses, grasses, &c.

Florian, JEAN PIERRE DE, a French novelist and fabulist, who was born in 1755, and died in 1794. He was a literary pupil of Voltaire, by whom he was held in very high esteem. He wrote two prose romances (*Numa Pompilius* and *Gonzalve de Cordoue*), and a number of pastorals, *nouvelles*, plays, and fables. He appears to most advantage in his *Fables*, which are neatly and often wittily turned. His romances are cold and languid in interest; they are fair examples, however, of the correct but colourless French prose of the 18th century.

Floriculture. See FLOWERS (FLORISTS'), GARDENING.

Florianopolis (formerly known as *Desterro* or *Santa Catharina*), capital and seaport of the state of Santa Catharina, Brazil, on the west coast of Santa Catharina island, 240 miles NE. of Porto Alegre; pop. 40,000 (including many Germans).

Florida is a large peninsular state in the extreme south-east of the United States, bounded E. by the Atlantic Ocean, N. by Georgia and Alabama, SW. by the Gulf of Mexico. It lies between 25° and 31° N. lat. and 80° and 88° W. long. The state is about 375 miles in length, and about 90 miles in mean breadth, its coast-line embracing about 1150 miles, and its area 58,680 sq. m., or 37,555,200 acres. About one-fifteenth of this area is water surface. Florida has nineteen navigable rivers, making an aggregate of 1000 miles; swamps and marshes are still extensive, though in many parts draining operations have been successfully carried out; lakes and isolated ponds number at least 1200. Of the lakes the largest is Okeechobee, a shallow fresh-water expanse of about 1000 sq. m., in the southern part of the peninsula. The Everglades (q.v.) form a delta-like expansion of this lake; more than five million acres were here originally under water, but drainage schemes have relieved great portions of land, which have proved peculiarly fertile. The geological formations of Florida have been found to be the equivalent of the Tertiaries of the Paris and Thames basins; there are indications that there is an upheaval of the land still in slow progress—a fortunate circumstance from the point of view of the draining engineers. The best bays, harbours, and estuaries are Fernandina, St John's River, St Augustine, Indian River, Key West, Caloosahatchie, Charlotte Bay, Tampa Bay, Cedar Keys, Deadman's Bay, Apalachee Bay, Appalachicola, St Andrew's Bay, and Pensacola Bay. The long coast-line is dotted

with very numerous islands of all sizes, from Santa Rosa and Key Largo, 30 to 50 miles long, to the smallest possible sandy keys.

In climate and products Florida is like a great tropical island. It is cooled by delightful seabreezes from the gulf, making the climate remarkably equable and healthful; and the state is a favourite winter-resort, although malarial fevers prevail in some parts, and yellow fever has occasionally visited the seaports heavily. Even in the southernmost portions the summer heat is not extreme. The range between the mean summer and winter temperature is only about 20°. The soil, while much of it seems a sterile sand, is helped to fertility by the moisture, but more especially by the extensive use of artificial manures. Florida furnishes abundantly the rich fruits and valuable products of the tropics. Large areas are devoted to orange orchards, while lemons, limes, grapes, pine-apples, bananas, pears, guavas, &c. grow with equal luxuriance; and coffee, rice, cotton, and tobacco are natural products. Sea-island cotton, so valuable, and elsewhere limited to a few islands, here grows far inland. Coconuts also are grown in the subtropical region. Horticulture is one of the most profitable pursuits, and market-gardening has assumed considerable dimensions in many parts of the state. An abundance of fruits and vegetables may be had fresh every month in the year, and during the winter and early spring months they are in great demand in northern markets. Florida is not rich in minerals, the most important being the extensive deposits of lime phosphates found through a large part of the peninsula, and in places rich in mammalian and reptilian remains. The *coquina*, a shell conglomerate, furnishes an excellent building-stone; but concrete of sand, shells, and lime or cement is now more extensively employed, as in the vast hotel at St Augustine (q.v.). Mineral springs are numerous. Large tracts of alluvial swamp and shallow lake-lands are being reclaimed by drainage. Next to these are the low hummocks or bottom-lands, dry enough for cultivation, and producing large crops of cotton, sugar-cane, grain, fruits, and vegetables. The high hummocks have a dark, gray soil, very rich at first, but soon running out if not kept well fertilised. Then come first-class pine, oak, and hickory lands, sandy, but containing a good deal of lime. Oranges and other citrus fruits grow well on these lands. There is a second-class pine land that is barren, but supplies a tolerably good pasturage. The forest trees are live-oaks and other evergreen oaks, cypress, hickory, magnolia, holly, great dogwood, bay-laurel, satinwood, lignum-vitæ, mahogany, palmettos, Jamaica kino, mangrove, manchineel, torch-wood, &c. Figs are grown in great abundance. Indian corn is largely raised. Numerous wild animals abound in the central and southern parts of the state, such as the black bear, the cougar, the panther, wild-cats, wolves, foxes, raccoons, opossums, fish-otters, deer, and smaller game; alligators are found in nearly all rivers, lakes, and swamps; turtles are taken among the keys; and manatees are found on the Atlantic side as far north as latitude 27°.

Among the industries of Florida is a large business in the production of pine and other lumber, and live-oak timber for shipbuilding. The preparation of naval stores, turpentine, tar, rosin, and pitch employs many hands; cigars are manufactured in large quantities; all along the coast there are valuable fisheries, oysters abound in many parts, and the inland waters also teem with fish; and the evaporation of salt, the production of cotton-seed oil and meal, the manufacture of fertilisers from the phosphate deposits, and sponge and coral fisheries are among the profitable industries.

The economic development of Florida dates from about 1835, when many energetic northern capitalists began to invest and settle in the country. The phosphate industry has shown very rapid growth; the making of cigars and cigarettes has greatly developed in the southern part of the state. The total manufacturing product of the state in 1920 was \$213,326,800—about nine times what it was in 1890. The forest area, mainly in the north-west, yields a large part of the total manufacturing produce, in timber (pitch-pine), tar, turpentine, and rosin. Most of the 3200 miles of railway were constructed in and after 1880. Spite of a State university, many public schools, an agricultural college, and several military and other colleges and seminaries, education is not advanced in Florida, the large negro population being responsible for much illiteracy. Pop. (1830) 34,730; (1850) 87,445; (1870) 187,748; (1880) 269,493; (1890) 391,422; (1900) 528,542; (1910) 751,139; (1920) 968,470. Tallahassee, a small city, is the capital; Jacksonville, Tampa, Pensacola, Miami, and Key West are the largest towns.

Florida was discovered on Easter Day (*Pascua Florida*), 1513, by Juan Ponce de Leon (q.v.). In 1539 it was explored by De Soto (q.v.), and in 1565 a body of French Calvinists, who had established a settlement three years previous, were butchered or driven out by the Spaniards. The latter held possession till 1763, when Florida was ceded to England in exchange for Cuba. The Spanish regained the country in 1781, and two years later were confirmed in their occupation by the Peace of Versailles. Florida was ceded to the United States by Spain in 1819, received a constitution in 1833, and was admitted into the Union as a state in 1845. In 1835-42 it was the theatre of a desperate war between the aborigines (Seminoles, q.v.) and the white settlers, a war which was only terminated after a sacrifice of hundreds of lives, and at a cost to the United States government of over \$20,000,000. Florida passed an ordinance of secession, 10th January 1861, siding with the Confederates; but the battle of Olustee in February 1864 was the only important fight within its boundaries. It was one of the first states to return to the Union, framing a new constitution in October 1865, but was not re-admitted till June 1868. It is represented in the United States Senate by two members, and in the House of Representatives by four. See Norton, *A Handbook of Florida* (1892); Whitehead, *The Camp-fires of the East* (1891); Powell, *The American Siberia* (1892); and works by Ward (1898), Simpson (1920), and Harper (1921).

Florida, capital of the Uruguayan department of the same name, 67 miles N. of Montevideo by rail; pop. 13,500.—The *department* has an area of 4700 sq. m., and a pop. of 66,000.

Florida Strait is the name given to the channel separating the American state of Florida from Cuba on the S. and the Bahamas on the E. It is 310 miles long, and varies from 50 to 100 miles in width, and from 2220 to 5070 feet in depth. The Gulf Stream flows through the strait at a rate varying from $\frac{1}{2}$ mile to 5 miles an hour.

Florin was a gold coin first struck in Florence in the 11th century. It was the size of a ducat, and had on one side a lily, and on the other the head of John the Baptist. The silver florin, with the same designs as the gold florin, was first struck in 1181. These coins were soon imitated all over Europe. It was out of them that the German gold and silver gulden of the middle ages and the silver gulden of modern times arose. The gulden or florin was the unit of account in Austria. Till 1876 a florin or gulden of 1s. 8d. was the unit in the South German

States. The Dutch florin or guilder is also worth 1s. 8d. Edward III. of England issued a gold florin worth 6s. 8d. The English 2s. piece is called a florin; the 4s. pieces first coined in 1887 are double florins.

Florio, JOHN, the translator of Montaigne, was born in London about 1553. His father was a Protestant exile and Italian preacher in London, but his labours came to a discreditable conclusion. Wood says that for safety's sake he kept his family out of England till after the death of Mary. John Florio appears as a private tutor in foreign languages at Oxford about 1576, and two years later published his *First Fruits, which yield Familiar Speech, Merry Proverbs, Witty Sentences, and Golden Sayings*, accompanied by *A Perfect Induction to the Italian and English Tongues*. In 1581 Florio was admitted a member of Magdalen College, and became a teacher of French and Italian. He enjoyed the patronage successively of Leicester, the Earl of Southampton, and other noble persons. His next work was *Second Fruits, to be gathered of Twelve Trees, of divers but delightful Tastes to the Tongues of Italian and English men*, with, annexed to it, the *Garden of Recreation*, yielding six thousand Italian Proverbs (1591). His Italian and English dictionary, entitled *A World of Words*, was published in 1598. Florio was appointed reader in Italian to Queen Anne, and afterwards groom of the privy-chamber. In 1603 he published in folio his famous translation of Montaigne, of which it is praise enough to say that it is a version worthy of its original. A copy of this work in the British Museum bears the authentic autograph of Ben Jonson; another, that of Shakespeare, although its authenticity is more than dubious. At any rate it is certain from the *Tempest* that the great dramatist was familiar with the book. It was long believed that the pedantic Holofernes in *Love's Labour's Lost* was a study after Florio; but it is satisfactory to lovers of Montaigne to know that for this there is no foundation. Florio died of plague at Fulham in 1625. Second and third editions of his Montaigne appeared in 1613 and in 1632. A reprint of this noble monument of Elizabethan English was issued in 1892-93, with Introduction by Mr Saintsbury. See a study by the Comtesse de Chambrun (1921).

Florists' Flowers. See FLOWERS (FLORISTS').

Florus, generally, but on insufficient evidence, called L. Annæus Florus, was a Roman historian who flourished in the reign of Trajan or Hadrian, but of whose life we know nothing. He wrote an epitome of Roman history (*Epitome de Gestis Romanorum*) based mainly on Livy, from the foundation of the city to the time of Augustus, in an inflated and metaphorical style.—To the African-born poet, Publius Annius Florus, a friend of Hadrian, the *Pervigilium Veneris* has been attributed.

Flory. See FLEURY.

Flotation, a method of separating ores from gangue by forming a froth in which the ore particles rise with the bubbles. See COPPER (METALLURGY).

Flotow, FRIEDRICH, FREIHERR VON, an operatic composer, born at Teutendorf in Mecklenburg, 27th April 1812. He was at first intended for the diplomatic profession, but on his arrival at Paris in 1827 his sense of his own musical abilities was awakened, and he began to study under Reicha. His reputation was made by his earliest operas, *Le Naufrage de la Méduse* (1839), *Stradella* (1844), and *Martha* (1847), the last two characterised by pleasing melody and by the light and lively character of the music. Of Flotow's later operas only three have attained marked success—*Indra* (1853), *La Veuve Grapin* (1859), and *L'Ombre*

(1869). In 1856 he was appointed intendant of the theatre at Schwerin, but he resigned in 1863, and returned to Paris. He died at Wiesbaden, 24th January 1883. See Life by his widow (1892).

Flotsam, JETSAM, and LIGAN, terms of English law used to denote goods cast away from a ship that is wrecked or sunk. *Flotsam* is the term where the goods continue to float or swim upon the surface of the water; *jetsam*, where they are cast into the sea and sink; *ligan*, where they are sunk in the sea, but fastened to a cork, bladder, or buoy in order to be found again. Unless the owner appear to claim them within a year and day, goods in each of these states belong to the crown. Jetsam, flotsam, and ligan did not fall within the meaning of the term 'wreck' in its original meaning at common law. In that sense wreck was the part of the cargo of a lost ship that came to land and belonged to the crown. A grant of 'wreck' from the crown accordingly did not carry flotsam, jetsam, and ligan. At the present day, however, 'wreck' has come to include these classes of goods in the provisions of the Merchant Shipping Acts and other statutes. Statutory officers, called Receivers of Wreck, preserve wreck until it is claimed by the owner, or, if not claimed, sell it and pay the proceeds to the Exchequer. All such matters are under the general supervision of the Board of Trade. Jetsam must not be confounded with *jettison*, which means the throwing overboard of goods in order to save the ship, as where she must be lightened in a storm, or to gain speed to escape from capture, or for other good cause. In such a case the loss for the general good is apportioned by general average. See AVERAGE.

Flounder (*Pleuronectes flesus*), a common species of flat-fish, of wide distribution in the shallow waters round Britain and other north temperate countries. It is the Scots 'fluke,' and the Swedish 'flundra,' and differs but a little from the plaice and dab, two of the commonest neighbour-species. Like other flat-fishes, the flounder is asymmetrical, and swims or rests on one side, almost always the left, the eye of which is in early youth brought round to the upturned surface. It measures about a foot in length, and about a third as much between the dorsal and the ventral edge, without including the fringing fins. The colour of the eye-bearing surface varies in sympathetic adaptation to that of the sandy or muddy bottom on which the fish lives. The upper side is olive-green or brownish, sometimes with yellow spots; the blind side is yellowish-white, with small, dark points. The mouth-aperture is narrow; the teeth are conical, and most developed on the blind side; the dorsal fin begins at the eye; the scales are minute and smooth, but rough tubercles occur on the side of the head and along the bases of the dorsal and anal fins.

Of the two dozen related species, the Plaice (*P. platessa*), the Dab (*P. limanda*), the Smear-dab (*P. microcephalus*), and the Craig-fluke or Witch (*P. cynoglossus*) are the commonest. In the soles (*Solea*) the dorsal fin begins in front of the eye, and the upper eye is slightly anterior to the lower.

The flounders spawn at the mouths of rivers, and the young are hatched in May. The fish often leave the sea and go up the rivers, ascending the Avon to near Bath, and the Moselle as far as Trier. They are even able to thrive in ponds. Sea-birds prey largely upon them, breaking the bones to make swallowing possible. Though inferior to the plaice, the flounder is an esteemed food-fish. The Australian and New Zealand flounder is a Rhombosolea, and most excellent eating. See DAB, FLAT-FISH, PLAICE, SOLE.

Flour. See BREAD, FOOD, MILL, WHEAT.

Flourens, MARIE JEAN PIERRE, a French experimental physiologist, was born on 15th April 1794, at Maueilhaan, Hérault. An M.D. of Montpellier at nineteen, at Paris he became acquainted with the Cuviers, Geoffroy Saint-Hilaire, Destutt de Tracy, and Chaptal. He first attracted attention by a series of works dealing with the nervous system in its relations to the different sensations, wherein he sought to determine upon experimental grounds the specific sensational functions of the cerebellum, cerebrum, and corpora quadrigemina. After lecturing for Cuvier in 1828 and 1830, he received a professorship in the museum of the Jardin du Roi, and in 1855 at the Collège de France. In 1833 he was nominated perpetual secretary of the Academy of Sciences, and in 1840 he succeeded Michaud in the Academy. He also took some interest in politics; he was elected to the Chamber of Deputies in 1838, and was made a peer of France in 1846. He died at Montgeron near Paris, 6th December 1867. Flourens also wrote instructive books on the development and nutrition of the bones, on the skin and mucous membranes, on the longevity of man, on animal instinct and intelligence, on the works of his predecessors and contemporaries, Buffon, Cuvier, Geoffroy Saint-Hilaire, and Darwin, and a series of useful *Eloges Historiques* (3 vols. 1856-62).—His son, GUSTAVE, born at Paris, 4th August 1838, first distinguished himself by his book, *Science de l'Homme* (1865), a series of lectures on the origin of the human race, delivered at the Collège de France in 1863. Of ardent republican sympathies, he took a very active part in the Cretan insurrection against the Turks in 1866, and subsequently in the Commune at Paris, fighting in behalf of which he met his death on 3d April 1871.

Flower. The observations of childhood, like the popular language in which these so largely tend to survive, are apt to deny flowers altogether to plants in which these are not conspicuous. Yet the unmistakable succession of the flower by the fruit and seed compels us in some measure to argue back from the presence of one or other of these to the previous existence of flowers, even where they may not usually have been noticed, as, for instance, in the oak. The observant walks of spring and early summer soon convince us that not one even of the soberest forest-trees but has its blossoming time, while no one can escape noticing in mid-summer the abundant blooms of the grasses and nettles. Horticultural experience, too, convinces us that the overpowering majority of plants brought from other lands flower sooner or later if the right conditions can be insured them, and thus we gradually reach the generalisation that among the plants which exhibit stems and leaves, none save the mosses, the ferns and horse-tails, the club-mosses and selaginellas, with a very few other inconspicuous and unimportant forms, fail to agree in the production of flower and seed. We have here evidently a broad principle of classification, and if our knowledge of the reproductive function of the flower has meantime developed so far as to repeat the discovery of its definite sexuality, we shall feel the appropriateness of Linnaeus's general term of *Evident-flowering* or *Phanerogamia* (q.v.), yet also approve the mingled caution and speculativeness which made him apply that of *Cryptogamia* (q.v.) to the latter, since it was reasonable to suppose that the reproductive process (Gr. *gamos*, 'wedlock') evident (Gr. *phaneros*) in the former might in the latter be concealed (Gr. *kryptos*).

The examination of so many flowers, or even of a few representative ones, will have shown us that the central organs in which the seed arises exhibit considerable variety alike in number and detail. Thus, distinguishing the essential 'seed-box' as the *ovary*, we find that there are many simple

separate ones in the buttercup or the rose, while the apparently single ovary of the apple or the tulip turns out on section to be five- or three-celled respectively, each cell containing the future seeds or *ovules*. We find, too, above the ovary a surface usually viscid or hairy, to which pollen readily adheres, and this we call the *stigma*, noting also that while sometimes practically sessile upon the ovary, as in buttercup or poppy, this is oftener raised upon a column, the *style*.

Encircling the seed organs we find the *stamens*, their stalks or *filaments* bearing heads or *anthers*. We see the latter shedding forth a yellow dust, the *pollen*, the same as that which we have noted upon the stigma of some of the flowers. This suggests one or two simple experiments. If we cut off the stigma, or cover it so that pollen cannot reach it, the incipient seeds or ovules will never mature into seeds proper capable of germination. Conversely, if we remove the stamens of this and other flowers, so that the same isolation of the stigmas from pollen comes to pass, the same failure of the seed follows. Whereas, when pollination of any particular stigma is effected (whether by the natural agency of insects or the wind, or more convincingly, by the actual help of the experimenter), seed forthwith matures in the corresponding ovary. And if the pollen be from a plant exhibiting some characteristic varietal difference, the resulting seed, when grown in its turn, will show the influences of this 'crossing' in a more or less marked degree (see HYBRID, HEREDITY). In this way the conception of sex in flowers, of immemorial date as respects those of the Date-palm (q.v.), has been extended in quite modern times. The carpels and stamens being thus the 'essential organs,' we recognise as merely 'accessory organs' the parts lying external to these, despite their frequent conspicuousness and beauty. In both monocotyledons and dicotyledons we have usually two circles or *whorls* of these parts, but in the former they are usually very similar, and so are usually spoken of merely as inner and outer *perianth-whorls* respectively, and their parts as *perianth-segments*. In most dicotyledons the corresponding whorls are known as *corolla* and *calyx*, since the colour and magnificence of the blossom usually depend upon the former (Lat. *corolla*), while the latter is commonly reduced to a mere verdant cup (Gr. *calyx*). The parts of the corolla or *petals*, and those of the calyx (*sepals*) are hence usually recognisable at a glance, as in the buttercup or rose. Yet the corolla may be reduced to inconspicuousness, as in the Christmas rose or globe-flower, or even vanish altogether; while the calyx may assume splendours which would be noteworthy even for a corolla, witness the marsh-marigold or garden clematis. Petaloid characters may be even assumed by Bracts (q.v.). Sepals, and still more frequently petals, may become more or less completely *united*, as so familiarly in the common primrose. In monocotyledons both whorls of the perianth may unite, as in the lily of the valley. Peculiar specialisations of form also abound, especially in the corolla, witness pansy or balsam, dead nettle or snapdragon. The calyx, too, may have its peculiarities, as in wallflower or poppy. The very modes of their arrangement in the bud differ widely (see AESTIVATION); while the position and arrangement of the separate flowers opens up a new field of study (see INFLORESCENCE).

Applying to the essential parts corresponding collective names, we have then innermost of all the *pistil* or *gynæceum* (its separate or constituent members being termed carpels); next the *androeceum* of stamens. We have thus four whorls of organs, each presenting apparently independent

and often wide differences in different flowers; hence we understand how in the attempt conscientiously to take note of all this multiplicity of floral detail the nomenclature of descriptive botany almost inevitably became so intricate and cumbersome (see BOTANY) as to obscure and retard that very progress towards the recognition of the order and unity of the floral world which it was the aim of the whole science to reach. Keeping this aim, however, in view, we are compelled to rise from the description of separate plants to the problem of classifying them into groups (species, genera, orders, classes, &c.) according to the degree of their common resemblance. It soon becomes evident, as it did to the earliest systematists, that it is mainly upon the flowers that our classification must depend. And having seen the multifariousness of these, we are in a position to appreciate the aid of the Linnean or 'Artificial System' of orders and classes, when to ascertain or record all that is known of a new plant our primary task is but the simple one of noting the number of its carpels and stamens. We comprehend better, too, the reluctance with which the claim of the 'Natural System'—that classification must depend upon the sum of like characters—was conceded, since this principle leads us back to unravel all the perplexing intricacies of which the device of Linnæus so summarily cut the knots.

A principle of fundamental importance for the natural system was however reached, and descriptive botany made a vast step, from the empirical to the rational level, as the conception of the morphology of the flower (see MORPHOLOGY) became gradually established. Sepals and petals, stamens and carpels thus lost their utter distinctness, and fell into a single category with the leaves as the *appendages of an axis*; their differences thus becoming understood as specialisations for their respective physiological purposes, in no way inconsistent with fundamental unity of structure and development. The simplest observer soon realises that a sepal is a sessile leaf, and a stamen a stalked one, and only needs to dissect a double rose or a white water-lily to convince himself by the discovery of a perfect series of transitional forms between petal and stamen of the essential unity of these. The spiral instead of whorled arrangement which we find in some simpler floral types (Ranunculaceæ, &c.) is thus immediately intelligible as a transition to the ordinary phyllotaxis of leaves. But the botanist has hardly yet exhausted the more refined applications of this principle; thus, since a leaf may not only have stalk and blade, but side pieces or stipules, we have frequently to take note of these in the flower, just as in the analogous case of leaves reduced as bud-scales (see BUD). Nor does the utmost detail fail us: thus, since the stipules of opposite leaves, although normally separate (nettle), constantly tend to unite (wood-geranium) or may even develop like the ordinary leaves (bedstraw), so it happens in many flowers. What the descriptive botanist empirically termed the outer calyx or epicalyx of a strawberry or lady's mantle is thus rationalised as the united stipules of adjacent sepals; and similarly the perplexing whorl of external yet younger stamens in the Geraniums (q.v.) and a few other types is easily interpreted as similarly united stipular developments of the ordinary whorl of stamens. By help of the leaf, in short, we are learning more and more completely to interpret and unify the peculiarities of floral structure.

Returning to simpler cases, the union of sepals and petals not only recalls that of opposite leaves, but anticipates what we exceptionally find among stamens, as in the filaments of the mallows, or the anthers of the composites; or among the carpels in a majority of orders. That in the types with united

corolla such union of the inner parts should also be more frequent and thorough than in those of separate parts is not to be wondered at; hence, for instance, the clubbed stigma of the lily of the valley as compared with the distinctly lobed—i.e. more separate stigma of the tulip.

Another great series of structural differences becomes cleared up when we bear in mind that appendages, however crowded and united, must arise upon an axis, however shortened. One or more internodes of the floral axis are, indeed, occasionally well developed, as in a lychnis or a passion-flower; but, generally speaking, their growth is checked at a quite embryonic stage. Since the early days of the natural system great attention has been paid to the position and origin of the floral parts. In the lily or the buttercup the stamens are seen to arise directly under the gynaecium, and are accordingly described as *hypogynous*; in the strawberry they arise in a circle at about the same level as the bases of the young carpels, and are consequently termed *perigynous*; while in the iris or the rose they seem perched upon the very top of the ovary, which is hence described as *inferior*. From the distinctness of the floral axis (then termed *thalamus*), the orders of hypogynous dicotyledons with separate parts became grouped as *Thalamifloræ*, while those with perigynous or epigynous stamens and separate parts were termed *Calycifloræ*, from the apparent origin of the stamens upon what was commonly regarded as a united calyx. All this, however, becomes intelligible when we combine the study of vertical sections of the adult flowers with the facts of their development. In the simplest hypogynous type we see the whorls of floral appendages standing in regular succession upon the conical floral axis just as they developed; the internodes having all developed equally. In the perigynous type, however, we see that the growth of the upper portion of the floral axis has been outstripped by that of its lower and as it were more vegetative region, which hence grows up around it; the epigynous type thus being only the extreme case of this, just as in inflorescences the spike becomes flattened into a capitulum, and this finally hollowed at the apex, or rather raised at the circumference into a cup, or even flask, as in the case of the fig. See INFLORESCENCE.

The large body of dicotyledonous orders in which the petals were united were grouped as *Gamopetalæ*, and finally the small and apparently degenerate types in which calyx, corolla, or both were absent were termed *Incompletæ*. The convenience of this system is so great that it is still retained in the *Genera Plantarum* of Bentham and Hooker. Its importance, but also its dangers, may be well seen by comparing fig. 1, in which figures of types of as many well-marked Thalamifloral, Calycifloral, and Gamopetalous orders are paralleled within the single order Liliaceæ (fig. 2), when with these we reckon the closely allied Amaryllids. In the same way the wide contrast between the usually splendid Calycifloral or Gamopetalous and the inconspicuous Incomplete type might be paralleled within the range of a single order, witness rose and lady's mantle (Rosaceæ), or lilac and ash (Oleaceæ).

Though thus losing an absolute principle of classification, we gain a conception of simplicity underlying floral differences. From the mere empirical description of flowers as we find them we begin to penetrate the rationale of their development, to comprehend something of what we may call the principles of flower-making. Starting again from a simple and tolerably central type like that of the lily, we find among its immediate allies types here of increasing floral magnificence, there of diminished splendour and size; witness tulip and lily of the valley. We see how

the more magnificent types tend to be always few or single-flowered, while the smaller and more modest types bear flowers in abundance; how the former are more individualised examples of the ordinal type, while the latter seem more embryonic. The one type tends to be richly coloured, often indeed complexly marked; the other tends to be paler, even white or positively greenish. When departures from regularity of form occur it is the more splendid forms which become bilaterally

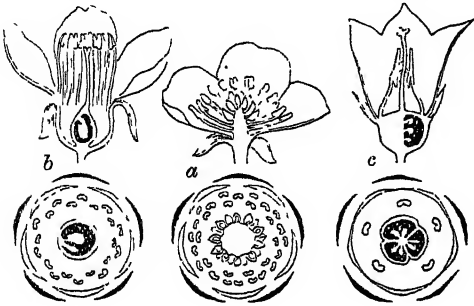

Fig. 1.

a, vertical section of buttercup (*Ranunculaceae*), showing hypogynous arrangement (*Thalamiflorae*); b, cherry (*Rosaceae*), showing perigynous arrangement (*Calyciflorae*); c, bell-flower (*Campanulaceae*), showing epigynous arrangement (here occurring along with the united petals of *Gamopetalae*). Each section is accompanied by its corresponding ground-plan or floral diagram.

symmetrical; and conversely it is among the more embryonic types that the petals or other parts become united. The more vegetative habit of the lily of the valley as compared with that of the tulip is here of interest, since we can correlate this obvious constitutional difference with the facts already outlined, or with such an otherwise incomprehensible detail as the production of many ovules by the tulip, but of few by the more vegetative and consequently less reproductive blossom of the lily of the valley. Even were such facts comparatively isolated they would be suggestive; but a wider examination of the monocotyledons brings us face to face with the existence of the same contrast in groups of all extent. Those extreme types, as it would seem, at once of floral differentiation and of vegetative habit, which we know as grasses and orchids, are alike clearly referable to the simple liliaceous ground-plan of structure (see the floral diagrams in fig. 3), and the question hence arises—must we not regard these simply as extreme variations, greater in degree, but of no different kind than those which we have

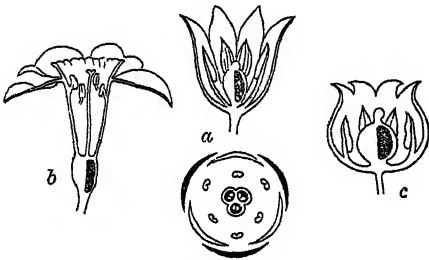

Fig. 2.

a, vertical section of tulip, with parts all separate; b, narcissus, with inferior ovary; c, lily of the valley (*Convallaria*), with united perianth and adherent stamens. The floral diagram of the tulip, however, applies to all.

recognised among the *Liliaceae* proper? An examination of the orchids or the grasses themselves, still better of the arums, yields a similar result: the

floral orchids have their degenerate vegetative types, small, many-flowered, few-seeded, it may be even green; while even the typically crowded and degenerate florets of the arums may obtain, by the production of a highly coloured spathe, no small measure of floral magnificence. Passing to the dicotyledons we find the same result in reviewing them order by order, often indeed genus by genus (e.g. *Clematis*, *Thalictrum*, *Delphinium*, and *Senecio*). We thus comprehend the otherwise perplexing fact that of all supposed natural alliances it is that of the Incomplete which has most broken down, their 'orders' having long been recognised as the degenerate (i.e. vegetative) representatives of many widely distinct orders. The bearing of these considerations upon our theory of variation and consequently upon our general conception of evolution cannot here be entered upon: it must suffice if the existence of order and simplicity amid the infinitude of floral detail has been rendered more apparent.

The problems just now raised will be found more fully discussed under *VARIATION*, &c.; for the classification of flowering plants, see some of the books noted under *VEGETABLE KINGDOM*. The structure of the stamen, with the development of its pollen, are naturally described under *STAMEN*, and the process of fertilisation of the ovule under *OVULE*; while that deepest interpretation of the flower which compels us to view the phanerogam as not only the most evolved of the cryptogams, but really the most profoundly cryptogamic of them all, is necessarily given under *GYMNOSPERMS*, since a knowledge of these in relation to the higher

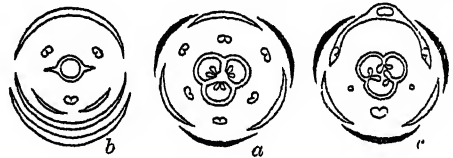

Fig. 3.

a, floral diagram of *Liliaceae*; b, reduced modification of this usual in *Grasses* (q.v.); c, specialised modification usual in *Orchids* (q.v.).

cryptogams is indispensable. It remains, however, to glance briefly at the flower from the physiological side, in its adaptations to fertilisation.

Fertilisation of the Flower.—From the frequent separation of the sexes in flowers borne upon the same individual (*monœcism*—e.g. *Begonia*), or upon different individuals (*diœcism*—e.g. nettle, dog-mercury, red or white campion), it is evident that pollen must somehow be borne from male to female flowers. The artificial assistance of the wind-fertilised Date-palm (q.v.) has been already referred to as indicating some comprehension of the process from immemorial times. The hermaphroditism of most flowers, however, long misled botanists into thinking of the flower as normally fertilised by its own pollen; and so obstinate was this error that even the publication of Sprengel's *Secret of Nature Discovered*, with its wealth of careful observation even supported by accurate figures, failed to dispel it (see *BOTANY*); and this admirable book fell into oblivion until its rehabilitation by Darwin, followed by Delpino, Hildebrand, Fritz Müller, and many subsequent investigators.

Just as the familiar spores of ferns or horse-tail are scattered by the wind, so it is with the pollen of such primitive flowers as those of *Conifers* and *Cycads* (see *GYMNOSPERMS*). In the cryptogams, however, germination of the spores takes place upon the ground apart from the parent plant altogether; but in the flower, since the female spore or embryo-sac is always retained within its sporangium or ovule, and this in turn in monocoty-

ledons and dicotyledons (angiosperms) within a carpellary leaf which usually does not even open until the maturation of the fruit (see FRUIT), it is manifest that only those male spores (pollen grains) can be effective which are conveyed to the receptive surface (stigma) of the carpellary leaf, and there germinate until they succeed in penetrating as far as the ovule and embryosac. Hence the utility of wind or insects for the transport of pollen. In this regard it is evident that the help of spore-eating insects might early have been of service, since spores might readily thus be conveyed adhering to their bodies. It has been already noted (see CHLOROPHYLL) that the colouring matter of flowers, like that of vernal and autumnal leaves, may be associated with phases in the constructive or destructive changes of chlorophyll. Since the reproductive process especially checks those of vegetation, we have here an agency for the production of floral colour, which, by rendering the reproductive shoots more conspicuous to insects, would be constantly aided by natural selection. Upon the latter process, indeed, the customary explanation of the origin of floral colour and markings solely depends. An analogous advantage for the attraction of insects would be given by the overflow as 'nectar' of any excess of the sugary sap so largely used up by the flower itself, or similarly by the disengagement of perfume. A constant adaptation between flower and insect being in such ways established, further specialisations arise. Thus, while in many flowers—e.g. crucifers, the stamens and stigmas are ripe simultaneously, a 'want of time-keeping' is frequently observed, the stamens becoming *protandrous*—i.e. ripening before the stigmas, as typically in *Geranium* (q.v.), so that self-fertilisation is impossible, and a physiological separation of the sexes (*dichogamy*) is thus insured. Or where the ripening remains simultaneous, two or even three forms of flower (*dimorphism*, *trimorphism*) may occur in different individuals of the same species, so rendering cross-fertilisation by insects indispensable (see PRIMROSE, LYTHRÆÆ). The individual flower may also become peculiarly specialised: thus, the nectary may become so deep as to be accessible only to insects with long proboscis, as bees to the exclusion of flies, butterflies and moths to the exclusion even of bees, it may be even to some particular species only. Birds, too, may replace insects (see HUMMING-BIRD, HONEY-EATER). Mechanical adjustments are also to be found in many of the more specialised types, witness the stamens of the sage, which are rocked forward by the bee on entering the flower so as to dust his back with pollen just where it will be rubbed off upon the stigma of another flower. The most extraordinary variety and complexity is, however, that presented among the Orchids (q.v.).

How some flowers (e.g. *Stapelia*, *Rafflesia*) attract the services of flesh-flies by the odour and even colour of carrion; how others like *Arum* and *Aristolochia* may entrap and detain the fertilising insect until well dusted with pollen, are examples which can but be mentioned. Nor can we describe the defences of flowers from rain or from ants, &c. (see, however, CATCHFLY, HEATH, &c.).

In wind-fertilised plants the flowers are usually comparatively small and inconspicuous, but numerous and closely aggregated, often in spikes, heads, or catkins; the floral envelopes are usually small and greenish; one or both whorls are indeed frequently absent (Incompletæ). The stamens are few but often versatile as in grasses, the ovary reduced, commonly only one-seeded, but with one or more styles and stigmas, the latter often exuberantly branched or feathery, so catching the small pollen-grains. The stigmas are ready before the pollen is shed (*protogynous dichogamy*);

and flowering often takes place as in many forest-trees before the development of the leaves. The pollen grains may be lightened with air-sacs as in the pine, may be helped by gravitation as in maize and bulrush, where the male inflorescence grows higher than the female, or may be scattered explosively as in the nettle or artillery plant. The utility of all these special characters of wind-fertilised flowers is thus no less obvious than that of the peculiarities of those dependent upon the visits of insects, and the natural selectionist is hence accustomed to draw from both of these remarkable sets of adaptations many of his strongest arguments for the development of even the most complex organic structures through the cumulative selection of minute spontaneous varieties (see DARWINIAN THEORY). Some facts, however, such as the repeated development of the characters of wind-fertilised flowers in quite unrelated types, seem rather to indicate the possibility of a constitutional interpretation similar to that indicated on the previous page (see VARIATION).

It is thus manifest that the flowers of every species in nature thus invite and reward an observant interest far other than that of the mere collector, systematist, or even morphologist. Further information will sometimes be found under individual headings—e.g. CAPRIFICATION, GERANIUM, &c.

See Muller's *Fertilisation of Flowers* (trans. 1882); Knuth's *Handbook of Floral Pollination* (1906-8); Kerner's *Natural History of Plants* (trans. 1902); Henslow's *The Origin of Floral Structures through Insects and other Agencies* (1888), and *The Making of Flowers* (1891); Eichler's *Flower Diagrams*; several of Darwin's works; also PHYSIOLOGY (VEGETABLE) and books there noted.

Flower, SIR WILLIAM HENRY, K.C.B. (1892), was born at Stratford-on-Avon in 1831, served as assistant-surgeon in the Crimea, and afterwards became demonstrator of anatomy at the Middlesex Hospital. He was appointed in 1861 conservator of the Hunterian Museum, in 1869 Hunterian professor of Comparative Anatomy and Physiology, and in 1884-98 was director of the natural history departments of the British Museum. F.R.S., LL.D., and president of the British Association (1889), he wrote on human nerves (1861), on the osteology of the mammalia (3d ed. 1885), on the horse, on museums, on the Monotremata and the marsupials, and on the brain of apes and lemurs. He died 1st July 1899. See Life by Cornish (1904).

Flower-de-luce, the old name for the common species of Iris (q.v.), or for the heraldic emblem conventionalised therefrom. See FLEUR-DE-LIS.

Flowering Currant, an ornamental shrub, *Ribes sanguineum*, whose flowers change from white to pink. See RIBES.

Flowering Plants. See PHANEROGAMIA, and articles there referred to.

Flowering Rush (*Butomus umbellatus*), a monocotyledonous plant usually reckoned under the order Alismaceæ, easily recognised by its large linear three-edged leaves (which are said to cut the mouths of cattle, whence the Greek form of the generic name), and by its umbel of rose-coloured flowers, which Ovid tells us render the plant a special favourite of Flora. The bitter rootstock was formerly official, and was also used (as still in some parts of eastern Europe) as a source of starchy flour, and the leaves are sometimes plaited. It is not uncommon in ponds and wet places, and is well worth introduction where such conditions are present.

Flowerless Plants. See CRYPTOGAMIA, and articles there referred to.

Flower-lore. See PLANT-LORE.

Flower of Jove (*Agrostemma flos-Jovis*), a pretty caryophyllaceous plant, with heads of purple

or scarlet flowers, and leaves silky white with hairs. Other species are common in gardens—e.g. *A. celastrosa* (Rose of Heaven), and *A. coronaria*. The genus, also known as Rose campion, owes its technical name to the ancient use of the flowers in crowns and garlands.

Flower-pots are utensils of culture whereby plants are rendered portable at all seasons. They are used in one form or another in all countries where gardening as an art is practised. In Britain and on the Continent they are made in all sizes, from the *thumb-pot* of 2 inches in depth used for potting tiny seedlings and delicate cuttings, to extra large ones of 3 feet to accommodate large palms, tree-like camellias, &c. Their diameter is usually equal to their depth. They are glazed or unglazed, it being immaterial to their utility whether they are so or not; and are plain or ornamental and artistic according to taste and the purpose for which they are intended. In order to be healthy receptacles for the roots of plants, they must be provided with perforated bottoms to admit of the free egress of water from the soil. Saucers are made for all ordinary sizes of flower-pots for use in rooms and other places where drip would be inconvenient or undesirable.

Flowers, in Chemistry, is a term originally given by the alchemists to the sublimes which arose, or appeared to grow, from certain bodies capable of undergoing volatilisation when subjected to heat; thus, *flowers of antimony*, *flowers of arsenic*, *flowers of benjamin* or *benzoin*, *flowers of sulphur*, *flowers of zinc*, &c. See ANTIMONY, &c. The word is also applied to fungous growths, as *flowers of tan*. See MYXOMYCETES.

Flowers, **FLORISTS'**, are those numerous forms of flowering plants which, having an inherent tendency to vary in the colour and size of their flowers and in habit when reared from seed, have received special attention in cultivation and in selection with the view of bringing their floral qualities up to ideal standards of excellence formed by the common consent of florists for each particular variety. Thus, for instance, the pansy, one of the most familiar of florists' flowers, is in all its wonderful variety the progeny of *Viola tricolor*, a widely distributed native of Britain. Its natural tendency to seminal variation rendered it a very facile subject in the hands of the florist, as may be seen by comparing the puny, unequal, and flabby flowers of the natural forms of the species with the large, circular, substantial, and brilliantly coloured blooms of the florists' varieties. This has been achieved by the intelligent application of the principle of selection, the object being the attainment of a given ideal respecting the size, form, substance, and colour of the flowers. The petals are the only parts affected in this case; they are enlarged in breadth and length, their substance or thickness is increased, and their outline is rendered more symmetrical, but the other organs of the flower are not changed. As with the pansy, so it has been with every other kind of plant bearing single flowers in the florists' category. It is different with those kinds whose flowers are double, such as the carnation, anemone, hollyhock, ranunculus, rose, &c. In these the essential organs of the flowers have been wholly or partially metamorphosed into petals. But the so-called double flowers of dahlias, chrysanthemums, and other forms of the natural order Compositæ are not really double in this sense; the fertilising organs are not changed to petals in their case; but the tubular florets of the disc assume the strap-like shape of those of the ray, and hence the semblance of double flowers in such cases.

The Dutch were the first among European nations to cultivate systematically florists' flowers: to them is due the merit of having brought the Tulip (q.v.), the hyacinth, the anemone, the ranunculus, and the rose to the high degree of perfection their numerous varieties now present. The French florists have also had a large share in the improvement of the three last-named classes. British florists have distinguished themselves more particularly in the production of auriculas, polyanthus, the phlox, pentstemon, carnation, pink, hollyhock, dahlia, pansy, pelargonium, &c. But the Chinese and Japanese appear to have fostered the culture of many flowers in the same way as the European florists, long prior to the latter having done so. Camellias, azaleas, and tree-peonies were some of their favourite florists' flowers long before Europeans had much intercourse with the Chinese.

New varieties are obtained chiefly from seeds, but some also are obtained by *sports*, which, in the language of the florist, mean freaks of nature. Thus, the flowers on a certain shoot of a plant may perhaps exhibit features of a kind novel and distinct from those of the parent, and the variety, if worthy of being perpetuated, is propagated by cuttings or by grafting, according to the mode best adapted to the kind. If the variation becomes *fixed* or permanent a new sort is thereby obtained without direct seminal intervention; but this does not always follow, although a keen florist will never allow such an opportunity to escape without an attempt to improve it. Varieties of special merit in any class of florists' flowers can only be perpetuated by cuttings, layering, grafting, or division, because they cannot be relied upon to reproduce themselves from seed.

Fludd, **ROBERT**, an English physician and mystic, born at Milgate in Kent in 1574. After studying at Oxford, he spent some years travelling on the Continent, where he became acquainted with the writings of Paracelsus. On his return to England he settled as a physician in London, where he died in 1637. Fludd (Lat. De Fluctibus) was the author of a theosophic system, the distinguishing features of which were the conception of man, the microcosm, as an analogy, in a physico-spiritual sense, of the universe or macrocosm, and the belief that the laws of the physical universe were dominated by two fantastic principles called the 'northern or condensing power,' and the 'southern or rarefying power.' His views called forth adverse criticisms from Gassendi, Kepler, and others.

Flue. See CHIMNEY, WARMING.

Flüelen. See LUCERNE (Lake of).

Flügel, **JOHANN GOTTFRIED**, German lexicographer, born at Barby in 1788, travelled as a merchant to North America, and in 1824 was appointed *lector* of the English language at Leipzig, where in 1838 he became United States consul, and in 1848 agent in Germany for the Smithsonian Institution. He died 24th June 1855. He prepared a standard dictionary of English and German (1830; 4th remodelled edition, by his son Felix, 1891). His son Ewald Flügel (1863–1914), born at Leipzig, was professor of English Philology in Stanford University, and began a *Chaucer Lexicon*.

Fluid. In a solid body the constituent particles never move far from a certain position of equilibrium. In a fluid the particles can move about with greater or less freedom from one part of the body to another. All liquids, vapours, and gases are therefore known as fluids. All fluids are perfectly elastic; but liquids are highly incompressible, while gases can easily be compressed. In every actual fluid there is more or less frictional resistance to the molecular motions; but it is often advantage-

of fluor spar, CaF_2 , with two parts of sulphuric acid, H_2SO_4 , when the vapours of hydrofluoric acid, HF , are evolved, whilst sulphate of lime, CaSO_4 , is left in the still. The dense acid vapours are conducted through a lead pipe into a lead receiver or bottle surrounded by a freezing mixture of ice and common salt. The acid is generally mixed with water when desired to be kept for some time. When the most concentrated hydrofluoric acid is required, the still and receiving vessel must be made of platinum. The other metals are not suitable for such apparatus, as they are rapidly corroded by the acid. When prepared in its strongest form, hydrofluoric acid has the density of 1.060, and is a colourless, fuming liquid of great volatility, which boils at 67° (19.4°C.). Not only does hydrofluoric acid corrode and dissolve the ordinary metals (excepting lead and platinum), but when placed on the skin it produces a severe burn owing to its caustic nature. The most important property which hydrofluoric acid possesses is its power of eating into and dissolving glass, which admits of its application in the etching of characters upon glass, as in thermometer tubes, and for eating away greater or less thicknesses of plates or sheets of coloured glass, so as to produce a variety of shades. See GLASS, and GLASS-PAINTING. The acid may be kept without any difficulty in bottles made either of paraffin-wax or gutta-percha.

Fluorotype, a photographic process, suggested by Robert Hunt in 1844, in which salts of fluorine acid were employed; but, as the impression was not very strong, the plate had to be afterwards steeped in a weak solution of proto-sulphate of iron.

Fluor Spar (FLUORITE, BLUE JOHN, DERBYSHIRE SPAR) is the only common mineral in which fluorine is present in any large proportion. The fluorine is combined with calcium, and forms *calcium fluoride*, CaF_2 , consisting of 48.9 calcium and 51.1 fluorine; occasionally it also contains some calcium chloride, and now and again organic matter, which is sometimes so abundant that when the mineral is struck with a hammer it emits a fetid odour—hence the name *fetid-spar* (Ger. *stink-fluss*). Fluor spar occurs both crystallised and massive, the massive varieties exhibiting a crystalline structure; the crystals appear usually in groups, sometimes of the primary form, which is a cube, but often of secondary forms, of which there is great variety, as the octahedron, rhombic dodecahedron, &c. Fluor spar is sometimes colourless, but often green, blue, yellow, or red, more rarely gray, or even black, different shades of colour frequently appearing in the same specimen, and in the massive varieties beautifully intermixed. Its colours often rival those of the most beautiful gems; but it is of very inferior hardness, being scratched even by quartz. Its specific gravity is 3.15 to 3.20. It generally becomes phosphorescent when heated, although this is more remarkably the case with some varieties than with others; it is decomposed by heated sulphuric acid, with evolution of hydrofluoric acid as a pungent gas; and, this having the property of acting upon and corroding glass, fluor spar is used with sulphuric acid for etching on glass. Fluor spar is also used for ornamental purposes, being wrought into vases, &c., for which it was in high esteem among the ancients. But the greater abundance in which it is now obtained has diminished the value of ornaments made of it. It is very commonly associated with ores of tin, silver, lead, and copper, occurring chiefly in veins, but is also found by itself in drusy cavities in granite and in veins in crystalline schists, slate, limestone, and sandstone. It has been met with also in volcanic tuff in Italy and in canal-coal in the United States, where it occurs in Illinois, Jefferson Co., N.Y.,

Franklin Furnace, &c. It is found only in a few places in Scotland, and in insignificant quantity, but is nowhere more abundant than in England, particularly in Derbyshire and in Cornwall. In Cornwall it is used as a flux for reducing copper ore. In Derbyshire the blue massive variety is known to the miners as *Blue John*. The manufacture of ornaments of fluor spar is carried on to some extent in Derbyshire; and fluor spar is often called Derbyshire spar. It is also used for optical purposes.

Flushing (Dutch *Vlissingen*), a strong fortress and seaport of the Netherlands, in the province of Zealand, is situated on the south coast of the island of Walcheren, at the mouth of the Western Scheldt, which it commands. Formerly an important naval station, it was converted into a commercial harbour in 1865–73, and carries on an active trade with Java, England, and South America. A daily service of steamers connects Flushing with Queenborough (Kent) in England. There are outer and inner harbours, and, since 1875, a large floating-dock. Doubling of the harbour accommodation began in 1920. The inhabitants (22,500) are occupied mainly in shipping pursuits. Shrimps are taken. The town capitulated to the Earl of Chatham in 1809.

Flushing, formerly a post-village of Queens county, New York, but since 1897 included in the City of New York. It is situated on Flushing Bay, a branch of the East River.

Flustra, or SEA-MAT (q.v.), one of the commonest genera of marine Polyzoa (q.v.).

Flute (Fr. *flûte*, Ger. *flöte*, Ital. *flauto*), one of the oldest of wind-instruments, which originally had several varieties: one, in more modern times called *flûte à bec*, now developed into the Flageolet (q.v.); another, which was sounded by means of a hole in the side like the modern flute; and a third, used by the ancient Egyptians, in which the sound was produced by blowing into the open end of the tube. A modification of this last instrument is used still by the peasantry along the Nile.

The modern cone-bore flute consists of a tapered tube, in which the sound is produced by blowing with compressed lips into a large orifice near the top or wider end, which is stopped with a cork. Six holes in the lower end, to be covered by the first three fingers of both hands, serve to make the scale, supplemented by keys numbering from one to fourteen. The flute is what is called an octave-scaled instrument—i.e. by covering all the holes and lifting the fingers one by one in regular order, beginning at the bottom, the notes from D below the stave to C \sharp are made; then, by repeating this process and blowing a little sharper into the mouth aperture, the same notes, *an octave higher*, are produced. Another octave can be produced by cross-fingering, the total compass being about three octaves. Two additional keys at the bottom of the tube, worked by means of levers by the little finger of the right hand, give the notes C \sharp and C \flat below the stave.

The faults of this flute are that, as the holes must be placed where the fingers can reach them, they are not always in the exact places to be perfectly in tune, and the notes are not equal in quality. To meet these defects the flute has undergone more changes and improvements in modern times than any other musical instrument. The most important of these have been the cylinder bore and the system of fingering introduced by Theobald Boehm in 1832, and patented in England by Rudall and Rose in 1847. The modern cylinder flute, from the head downwards, is cylindrical, or all one width of bore, while the head-piece has a slight parabolic taper, and when combined with the Boehm finger-

ing it forms a nearly perfect instrument, with all the notes in tune and of practically equal quality of tone. The holes are placed where they make the correct notes, and to facilitate manipulation they are stopped by means of keys which can be worked conveniently by the fingers. The fingering of the scale on the Boehm flute is quite different from the ordinary flute; and many other modified systems, more or less founded on the old, have been devised, among which may be mentioned those of Siccama, Clinton, and Carte. It would occupy too much space to describe their methods in detail. The general appearance of the Boehm cylinder flute may be seen in the figure.

Flutes are usually made in cocco-wood, ebonite, silver, and gold, and vary in price from a shilling or two to about £180 for one made in 18-carat gold. The Boehm flute is very often made in silver, which is easily sounded and gives a fine liquid tone; it costs about 30 guineas. The ordinary cocco or ebonite Boehm flute costs from 18 to 30 guineas, according as it is mounted in German silver or silver. Except for military flutes, which are still made conical, the cylinder has almost completely superseded the cone bore.

The flute described above is what is known as the concert flute; but flutes are also made in a variety of smaller sizes for various purposes in E \flat , F, B \flat , and C; there are also D, E \flat , and F piccolos or octave flutes, which are much used in modern orchestral music. In construction, however, they are all much alike, and need not be further described. A bass flute, too, is sometimes used, the Boehm variety being simply a large flute, 32 inches long and 1 inch in diameter, and having a compass from the upper G of the bass stave upwards. Also, see FIFE.

The concert flute, from the sweetness of its tone and the comparative simplicity of its execution, is extremely popular as an amateur instrument, and a great variety of music is published arranged for flute and pianoforte; and, as it plays the same notes as the voice and piano, it can be made useful in all kinds of music. The flute is made great use of in classical music; Bach, Haydn, Handel, Mozart, Beethoven, Mendelssohn, and all the later writers giving it a leading part in their works; while Quantz, Kuhlau, and many others devoted themselves almost specially to writing for it. See T. Boehm's *Essay on the Construction of Flutes*, and C. Welsh's *History of the Boehm Flute*.—The so-called 'flute-stop' is one of the many stops of the Organ (q.v.).

Flute-mouths (*Fistulariidae*), a family of marine fishes, nearly allied to sticklebacks, remarkable for the elongation of the front bones of the head into a pipe bearing the small mouth at its apex. They live near the shore, and are widely distributed in the warm parts of the Atlantic and Indo-Pacific. There are but few species—e.g. *Fistularia tabaccaria*, and *Aulostoma chinense*. The Snipe-fish or Trumpet-fish (q.v., *Centriscus scolopax*) belongs to an allied family (Centriscidae).

Fluting, the mouldings in the form of hollows or channels cut vertically on the surface of columns. The idea is supposed to have been originally derived from the bundles of reeds tied together which formed the early columns of the Egyptians. Flutes were adopted by the Greeks as ornaments to their Doric, Ionic, and Corinthian columns, and were retained by the Romans in their architecture. The

Tuscan is the only style without flutes. In Doric (fig. 1) there are twenty flutes on the circumference, and the curves meet with a sharp edge.

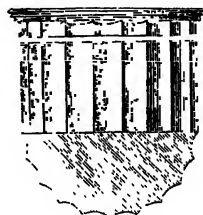

Fig. 1.

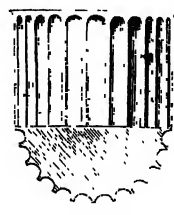

Fig. 2.

These curves are supposed, in Greek Doric, to be elliptical, and they are carried up across the necking to the base of the cap. In the other styles there are twenty-four flutes on the circumference (fig. 2). These are semicircular and separated by a small fillet, and, before reaching the necking and the base, are terminated with semicircular top and bottom.

Flutes are said to be cabled when they are filled in to about one-third of their height from the base with a convex bead. This is done to strengthen the column and protect the flutes. In countries where Roman remains are abundant, as in the south of France, fluting was sometimes adopted by the early medieval architects, as at Arles and Autun. In Italy also traces of this decoration are visible during the middle ages; but the flutes are not limited to the vertical form—in Romanesque Architecture (q.v.) they assumed many varieties of forms, such as curves, zigzags, &c., twisting round the shafts.

Flux (Lat. *fluxus*, from *fluo*, 'I flow'), a discharge generally from a mucous membrane. The term is applied more or less frequently to all preternatural fluid evacuations from the body, but especially to those from the bowels and from the uterine organs. Dysentery (q.v.) was long termed the bloody flux to distinguish it from simple diarrhoea. See also CATARRH, DISEASE, MEDICINE.

Flux is the term given to the substances employed in the arts to assist the reduction of a metallic ore and the fusion of the metal. *White flux* is an intimate mixture of ten parts of dry carbonate of soda and thirteen parts of dry carbonate of potash, and is mainly instrumental in removing siliceous impurities by combining with the silica to form a fusible glass; *black flux* is prepared by heating in close vessels ordinary cream of tartar (bitartrate of potash), when an intimate mixture of finely-divided charcoal and carbonate of potash is obtained. The latter flux, when mixed with finely-divided metallic ores, and the whole raised to a high temperature in a furnace, not only is useful in removing the silica by the action of the carbonate of potash as above described, but the charcoal withdraws the oxygen from the metallic oxide and causes the separation of the pure metal. For economy, limestone is employed in the smelting of iron ores. Fluxes are also employed in the operations of brazing and soldering to keep the surfaces to be joined free from oxide. Fluor spar, borax, protoxide of lead, and other basic substances are also used for fluxing. See IRON AND STEEL, COPPER, &c.

Fluxions. The method of fluxions and fluents was the name given after Newton to that branch of mathematics which with a different notation is known after Leibniz as the differential and integral calculus. Newton, representing quantities in the manner of Euclid and others by lines, looked upon

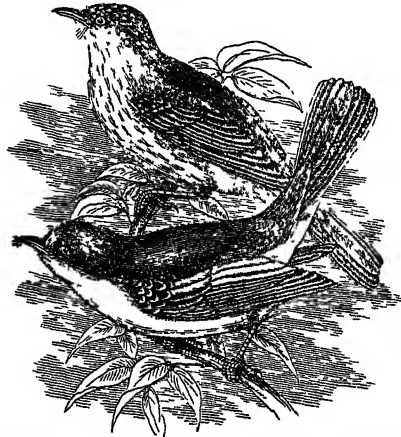

them not with Leibniz as made up of very small parts, but as described by a continuous motion. 'From considering,' says Newton in the introduction to his *Tractatus de Quadratura Curvarum* (1704—the first formal exposition of fluxions published), 'that quantities increasing in equal times and generated by this increasing become greater or less according as the velocity with which they increase and are generated is greater or less, I was in quest of a method of determining quantities from the velocities of the motions or increments with which they are generated; and naming the velocities of the motions or increments *fluxions*, and the quantities generated *fluents*, I came little by little in the years 1665 and 1666 upon the method of fluxions.' Instead of referring the rate of change of a dependent variable y directly to the independent variable x , as in the differential calculus, the method of fluxions refers each to time (t) considered as a uniformly flowing quantity. Thus, the fluxions of y and x , denoted by \dot{y} and \dot{x} , correspond to $\frac{dy}{dt}$ and $\frac{dx}{dt}$ respectively. The fluent of any quantity, say y , was denoted sometimes by $\int yx$, sometimes by y' . The notation adopted by Newton was on the whole clumsy, and has been abandoned for that of the differential calculus. In the method of fluxions the notions of prime and ultimate ratios take the place that limits hold in the differential calculus. The most logical and complete, as well as the most bulky, treatise that has ever appeared on fluxions is that by Colin Maclaurin (Edin. 2 vols. 4to, 1742; 2d ed. 2 vols. 8vo, 1801). See also CALCULUS, NEWTON (SIR ISAAC).

Fly, a popular name best restricted in its simplicity to the insects forming the order Diptera, but often so widely used with a prefix—e.g. butterfly, dragon-fly, may-fly—as to be virtually equivalent to insect. The flies properly so called have two delicate, unfolded wings with predominant longitudinal veins, hind wings modified into balancers (*halteres*) or rarely absent, and mouth parts in general adapted for sucking. The larva is usually a legless maggot, or has secondary 'false' legs. Gnats, midges, daddy-long-legs, gall-flies, blow-flies, bluebottle-flies, bot-flies, forest-flies, and house-flies are noticed separately. The 'Spanish fly' or *Cantharis* (q.v.) is a beetle.

Fly, a river of New Guinea, draining a considerable area in the centre of the island. In the upper part of its course it forms part of the boundary between British and Dutch New Guinea, afterwards flowing south-east to the Gulf of Papua, on whose shores it forms a wide delta. In 1875 Macfarlane and D'Albertis ascended it for 90 miles, and Everill in 1885 penetrated 200 miles to the junction of the Strickland, its chief tributary, up to which point the tidal influence is felt. Its total length within British territory is about 620 miles, and its discharge into the gulf is estimated at over two hundred thousand million gallons per day.

Fly-catcher, a name applicable to any of the numerous birds which make up the Passerine family Muscipidæ. The family includes a large number (over 40 genera and 280 species) of usually small-sized and often brightly coloured forms, very abundant in the warmer parts of the Old World and Australia, scarcer in temperate and colder regions, and wholly absent from North and South America, where they are represented by the Tyrant-shrikes or Tyrannidæ. The nature of the bill is a distinctive feature; it is strong, short, and somewhat swallow-like, laterally compressed towards the slightly hooked point, and with bristles on the broad and flat basal portion. The common British Fly-catcher (*Muscicapa grisola*) is a tiny

brownish-gray bird, which reaches our shores from Africa in early spring, and leaves again with its brood in autumn. The upper surface is mouse-coloured, the under side is whitish, with brownish-gray longitudinal spots. Its cry is a monotonous chirp; its habit, like that of its neighbours, is jeckily active. It remains quietly seated till an insect is observed, makes a successful dart, and

Spotted and Pied Fly-catchers (*Muscicapa grisola* and *M. atricapilla*).

returns to its perch. In nesting it is nowise shy; a beam in an outhouse, the side of a timber-stack, the branch of a tree trained on a building, and even a lamp-post are among the sites recorded. The parents have been seen to visit their nest with food for the young not less than 537 times in a single day, which indicates a marvellous quickness of movement and adroitness in food catching. The Pied Fly-catcher (*M. atricapilla* or *luctuosa*), with different colour, is common in south Europe, and has been recorded in Britain. There are ten other species in Europe and Africa. Among the other fly-catchers outside the genus *Muscicapa* are the Fantails (*Rhipidura*), with spreading tails, in oriental and Australian regions; the beautiful long-tailed Paradise Fly-catcher—e.g. *Terpsiphone paradisi* of the East Indies; the important genus *Myiagra* of Australia and the Moluccas; the interesting Australian 'Grinder' (*Seisura inquieta*), which 'hovers' like a kestrel, descends rapidly to the ground upon insect prey, and emits a curious noise (comparable to that made by a grinder at work) just before alighting, or when poisoning a few feet from the earth.

Flying. See FLIGHT.

Flying Animals, in the strict sense, include most insects, birds, and bats, and these only. In past times there were 'flying reptiles' (*Pterodactylus*, *Rhamphorhynchus*), in which the outer finger was enormously elongated, and supported a wing-like expansion of the skin. In several ways these extinct forms were prophetic of birds, and certainly must be said to have had wings; but to what degree they were able to progress like birds in the air we do not know. For the true fliers, and for their interesting contrasts—e.g. between the wing of an insect and that of higher forms, or between the 'arms' of bat and bird—the relevant articles must be consulted; the present is devoted to a quite different set of animals, which are popularly called 'flying animals,' though they do not beat the air with wings.

(1) Among fishes, two very distinct genera (*Exocoetus* and *Dactylopterus*) have the power of

skimming for considerable distances above the surface of the water, their expanded pectoral fins forming a parachute (see FLYING-FISH). (2) Some species of lizards in the genus *Dracon*—e.g. *D. volans*—take short swoops through the air, the skin being stretched on several much elongated ribs, so as to form a sort of half kite on either side (see DRAGON). In some Geckos (q.v.)—e.g. the Californian *Phyllodactylus tuberculatus*—there is not a little membranous fringing of body, tail, and limbs. The flying powers of Wallace's 'flying frog' (*Rhacophorus*) have not been certainly established. (3) It is, however, among mammals that attempts at parachute flight are most frequent, and that not in one order but in three: Marsupials (*Petaurus*), Rodents (*Pteromys* and *Sciuropterus*), and Insectivores (*Galeopithecus*).

FLYING PHALANGER, or Flying Opossum (*Petaurus*), a genus of marsupials, natives of New Guinea and Australia, where they are called Flying Squirrels, Sugar-squirrels, &c. Nearly allied to the Phalangers, they are distinguished by a hairy membrane or fold of the skin extending along the flanks, and used as a parachute to enable them to leap to great distances. This membrane extends along both fore and hind legs almost to the toes, but does not appear behind the hind-legs, nor include the tail. They are capable of modifying their course in the air, although not of true flight; and their aerial evolutions are very graceful. They repose during the day, and become active in the evening, feeding on fruits, flowers, leaves, insects, &c. A New Guinea species is as large as a cat;

1, Flying Phalanger (*Petaurus tawuanoides*);
2, Flying Mouse (*Petaurus pygmaeus*).

one of the Australian species is scarcely larger than a mouse, and is called Flying Mouse. The genera *Belideus* and *Acrobata* have also parachutes. See PHALANGER.

FLYING SQUIRREL (*Pteromys* and *Sciuropterus*), two genera of squirrels (*Sciuridae*), the members of which have a fold of skin extended from the flanks between the fore and hind legs, by means of which they are enabled to take extraordinary leaps, gliding for a great distance through the air. The tail may also aid to support them in the air, as well as to direct their motion, its hairs being often extended laterally in a sort of feathery expansion, as in some of the flying phalangers. The genus *Pteromys* is especially well represented in the Indian region; *Sciuropterus* predominates in the north. The commonest Old-World species, the Polatouche (*S. volans*), from north-eastern Europe and Siberia, is about the size of a rat, grayish-ash colour above,

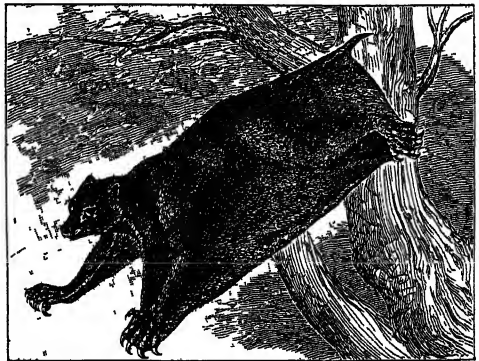

white below, the tail only half the length of the body. It lives solitarily in the forests where birches abound, is nocturnal in habit, vegetarian in diet. The most common North American species, the Assapan (*S. volucella*), abundant from the Gulf of Mexico to Upper Canada, is fully 5 inches long, with a tail of 5 inches additional, fur included. The general colour is brownish-gray, lighter beneath. In gliding from tree to tree it descends obliquely and with very rapid motion, perhaps for a distance of 20 yards, and always lands of course at a considerably lower level than that at which it started. The flying squirrels are all arboreal and nocturnal, and feed not only on nuts and young shoots of trees, but also on small birds. Some forms are readily

Flying Squirrel (*Sciuropterus volucella*).

domesticated; the fur is sometimes substituted for that of other squirrels. See SQUIRREL.

FLYING LEMUR, or Colugo (*Galeopithecus*), an aberrant Insectivore, with a parachute provided with special muscles, and even more efficient than in the preceding mammals. The hairy fold of skin begins behind the throat, includes fore and hind limbs as far as the claws, and extends along the tail to the tip. The animal has been observed to swoop over a distance of 70 yards. The claws are used in climbing; the lower front teeth are remarkably comb-like; the general colour is said to resemble mottled bark; the brain is very small.

Flying Lemur (*Galeopithecus volans*).

The flying lemurs are about 20 inches in length, are natives of the Indian Archipelago, inhabit lofty trees in dense forests, and feed chiefly on leaves and fruits, though said at times to eat

insects, eggs, and even small birds. They are nocturnal in their habits, and very inoffensive, scarcely attempting to bite even when seized. Their voice resembles the low cackling of a goose. The female bears a single young one at a birth, and has a pair of teats on each side near the armpits. The Pelew islanders greatly esteem them as food, but they have a rank, unpleasant smell. The zoological position of Galeopithecus is difficult to determine; it has been referred to the lemurs, to the bats, and with most justice to the Insectivores, while Wallace regards it as 'a lateral offshoot of some low form, which has survived during the process of development of the Insectivora, the Lemuroidea, and the Marsupials, from an ancestral type.' Two species (*G. volans* and *G. philippinensis*) are usually distinguished. The flying foxes (Pteropidae) are true bats and true fliers. See BAT, BIRD, DRAGON, FEATHERS, FLIGHT, FLYING-FISH, INSECT, PHALANGER, PTERODACTYL, SQUIRREL.

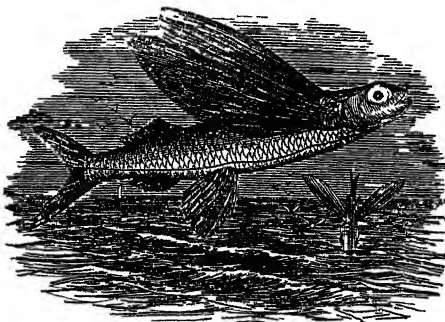

Flying Bridge. See FERRY.

Flying Buttress. See BUTTRESS.

Flying Column. See ARMY.

Flying Dutchman. A Dutch captain, Van Straeten, who was condemned, as a penalty for his sins, to sweep the seas around the Cape of Storms (the Cape of Good Hope) unceasingly, without ever being able to reach a haven. Seamen who saw his black spectral ship on the horizon quickly changed their course, and hastened to flee from his fatal influence. The notion that gave foundation to this legend is widespread in German mythology. The dead crossed the water in boats, and northern heroes were sometimes buried on land within their ships, sometimes placed in a ship which was taken out to sea and allowed to drift with the waves; while the same story is localised in the German Ocean, where Herr von Falkenberg is condemned to beat about the ocean until the day of judgment, on board a ship without helm or steersman, playing at dice with the devil for his soul. In the form of the legend chiefly current in England, the impious seaman's name is Vanderdecken, while his ship, which continually scours the seas, is, in all respects but reality, the image of a real ship. The legend gave Wagner the subject for his well-known opera, *Der fliegende Holländer*.

Flying-fish, species of *Exocoetus* and *Dactylopterus*, bony fishes which, though not indeed true fliers like birds or bats, are able to progress for some distance in the air, quite above the

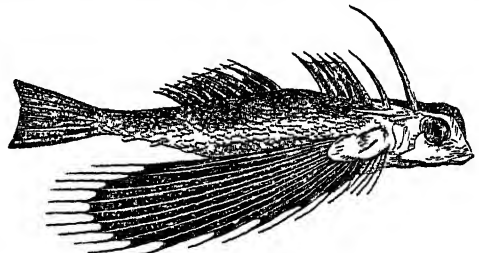

Flying-fish (*Exocoetus volitans*).

surface of the water. The genus *Exocoetus* is included in the family Scombroideae not far from the Pikes; while the genus *Dactylopterus* is referred to the Cataphracti, nearly allied to the Gurnards.

(1) *Exocoetus* (Flying Herrings).—There are over forty known species of this genus, mostly in the warmer seas. Two have occasionally been seen near British shores, one of which (*E. volans*) ranges from Australia through the Indian Ocean, while the other (*E. volitans*) is common in the Mediterranean. The long pectoral fins, which extend to the anus or even to the tail, form the most characteristic feature. The usual length of the body is about a foot. Their 'flight' has been much discussed, with the following general results. The fins are kept distended like a parachute, and are not moved like the corresponding appendages of birds or bats; deviation from a straight course, whether lateral or vertical, is due to air-currents, except when the animals in their progress dip their tail into the water and give a stroke; 'their flight is rapid, but gradually decreasing in velocity, greatly exceeding that of a ship going 10 miles an hour, for a distance of 500 feet;' they 'fly' most in rough weather, and farthest when more or less against the wind; in a calm their course is parabolic like that of a projectile, and close to the water, but they are liable to be lifted by the air-pressure over high waves, or by the wind on to the decks of ships; they leave the water when frightened, but also apparently from the mere exuberance of their constitutional activity. They swim and often 'fly' in shoals, and are chased by coryphænes (so-called 'dolphins') and other fishes, as well as by sea-birds. They are good for eating, and are often netted by the natives of the South Sea islands and elsewhere.

(2) *Dactylopterus* (Flying Gurnards).—Of this genus three species are known, abundant in the

Flying Gurnard (*Dactylopterus volitans*).

Mediterranean, the tropical Atlantic, and Indo-Pacific. The young have comparatively short pectoral fins, and cannot lift themselves, but the adults 'fly' after the above-described fashion. They are larger and heavier than the *Exocoeti*.

See Günther, *Study of Fishes* (1880); Möbius, *Fliegende Fische* (1878); and the article FLIGHT OF ANIMALS.

Flying Foxes. See BAT.

Flying Lemur. See FLYING ANIMALS, INSECTIVORA.

Flying Machines. See BALLOONS AND AEROPLANES.

Flying Squid (*Ommastrephes*), a genus of decapod cuttle-fishes (q.v.). The body is long, cylindrical, and pointed posteriorly, with two triangular fins, by help of which the animal can jerk itself out of the water, sometimes so high as to fall as a 'sea-arrow' upon a ship's deck. Like other cuttle-fish, they swim rapidly by forcibly ejecting water from their mantle or gill cavity. They are included among those Cephalopods which have the cornea of the eye open, so that the sea-water reaches the lens. Their internal shell or 'pen' is furnished with three diverging rays, and a hollow conical appendage. The species vary in length from 1 to 4 feet. Gregarious in their habits, they prey upon

shoals of mackerel and other fishes, and are themselves devoured by dolphins and other cetaceans, as well as by sea-birds. One species (*O. sagittatus*) is used very abundantly for bait in the Newfoundland cod-fisheries.

Flying Squirrel. See FLYING ANIMALS.

Fly Poison. This term includes the various preparations which are sold for the purpose of killing flies. Formerly powders on papers containing arsenic, and sweetened so as to attract the flies, were in general use. Since it has been found that paper dipped into a sweetened solution of quassia is equally efficacious, the poisonous article has been partly superseded.

Fly-trap. See DIONÆA.

Fly-wheel, a large wheel with a heavy rim fitted to steam-engines, or other machinery, in order to equalise the effect of the driving effort. Its action depends on the principle that matter in motion possesses kinetic energy—e.g. a body in having its velocity reduced is capable of doing work. The amount of work it can do depends directly on the mass of the body, and on the difference of the squares of its initial and final velocities, and is numerically equal to $\frac{m(v_1^2 - v_2^2)}{2}$. A heavy wheel thus becomes a reservoir of work when set in motion.

There are two principal cases in which the fly-wheel is commonly applied: (1) where the driving effort is intermittent or irregular, while the resistance to be overcome is for the time practically constant; and (2) where the resistance or work to be done is intermittent or irregular. The crank in a foot-lathe is a good example of the first case; the driving effort of the foot is only applied to the treadle on the down stroke, and the crank must rise independently of the effort. A fly-wheel attached to the crank-shaft effects this, the motion it acquires while the foot is acting gives it energy, and in virtue of this it is able to bring the crank up again into the proper position for the foot to act on the treadle. In single-crank engines the fly-wheel carries the crank over the dead centres (see CRANK), and whenever used in engines its function is to keep the speed steady during each revolution of the crank—i.e. to prevent unsteadiness during each turn; this it does by storing up energy during parts of the revolution when the effort is greater than the mean resistance, and giving it up again during those parts of the revolution when the effort falls below the resistance. In the gas-engine, where the effort (explosion) is often only applied during part of every second or third revolution, it does very important work. Its action must be clearly separated from that of the governor, whose function is to determine the mean speed or number of turns the engine shall make per minute; this the fly-wheel cannot in any way do—it can only keep the speed steady during each turn.

The second case is illustrated by a punching-machine. The engine need not be of sufficient power to directly force the punch through the metal, but with the aid of a fly-wheel it easily does it. The machine is so arranged that the actual part of each revolution spent in punching is very small; all the rest of the revolution the fly-wheel is storing up energy, nearly all the effort going in this. Then at the proper moment the work stored up is added to the direct work of the engine, and the punch forced through, the speed of the fly-wheel being proportionately reduced.

The principle of the fly-wheel is sometimes applied in other forms than that of a wheel—e.g. in fly-presses for stamping or coining metals, in which two heavy balls are fixed at the ends of a long lever, which is made to swing round with consider-

able velocity. The accumulated energy is given up at the moment of impact of the die upon the metal, and a force of great intensity called into play to compress the latter. Fly-wheels are not required in locomotives or marine engines (see STEAM-ENGINE).

Foch, FERDINAND, marshal of France (1918), was born at Tarbes in 1851, and educated at Metz. He served in the war of 1870, was professor at the École de Guerre in 1896–1901, and a brigadier-general in 1907. In the Great War he distinguished himself at the Maine, Ypres, and the Somme, became chief military member of the Supreme War Council, and as supreme head of the allied armies (1918) brought the war to a conclusion. He wrote *The Principles of War* and *The Conduct of War*.

Fochabers, a village of Elginshire, on the Spey, 9 miles ESE. of Elgin. Milne's Free School (1846) is the chief edifice. A mile north is Gordon Castle, the old 'Bog of Gight,' and the seat, since 1449, of six earls and four marquises of Huntly, five dukes of Gordon (the fourth of whom almost rebuilt it towards the close of the 18th century), and now of the Duke of Richmond and Gordon.

Focsani, or FOKSHANI, a town of Rumania, near the border-line between Moldavia and Wallachia, is in the former province, on the Milkoŭ, a tributary of the Sereth, about 100 miles NNE. of Bucharest. There is considerable river trade with Galatz, especially in grain. Near Focsani the Turks were defeated by the allied Austrians and Russians, 1st August 1789. Pop. 25,000.

Focus, in Optics, is a point in which several rays meet and are collected after being reflected or refracted, while a *virtual focus* is a point from which rays tend after reflection or refraction. The principal focus is the focus of parallel rays after reflection or refraction. See LENSES, MIRROR, OPTICS, PHOTOGRAPHY. For the focus of geometry, see ELLIPSE, HYPERBOLA, PARABOLA.—The *Focimeter* is an instrument for assisting in focusing an object in or before a photographic camera; it is usually a lens of small magnifying power.

Fodder (O.E. *fóðor*, cog. with Ger. *futter*), the food collected by man for the use of the domestic herbivorous quadrupeds. In English the term is commonly restricted to dried herbage, as hay and straw; but in other languages it is more comprehensive, and includes all the food of cattle, except what they gather for themselves in the field.

The principal part of the food of the domestic herbivora is furnished by grasses, most of which are eaten by them when fresh and green. Besides the surplus of corn cultivated for human food, they are also, to a considerable extent, dependent on the straw or dried herbage of the corn-plants for their winter provender; and that of many other grasses, cultivated on this account alone, is converted into hay for their use. Hay, being cut and rapidly dried before the nutritive substances have been collected in the seed, contains more nutritious matter than the ripened straw of the cereals. The most important perennial fodder grasses of Britain are Timothy, Foxtail, Cocksfoot, Tall Fescue, Meadow Fescue, and Hard Fescue. Perennial ryegrass, under certain conditions, may be added to the number. They should be all represented in ordinary mixtures for seeding land down to permanent grass. Italian ryegrass surpasses the perennial in its power of yielding a large crop under favourable circumstances in a rotation. In the United States the best grasses are Timothy, Red Top, or Rhode Island Bent, White Top, Orchard Grass, and June Grass or Kentucky Blue Grass.

Next to the grasses are ranked the Leguminosæ,

affording food for cattle in their seeds—as beans, peas, lentils, lupines, &c.—and in their herbage, on account of which many of them are cultivated, as clover, lucerne, vetch, tares, sainfoin, &c. When consumed green, the produce of these crops is usually termed forage or green forage. Some of them enter also largely into the composition of hay, being cut and dried with the grasses along with which they have been sown. Some of the Cruciferae are cultivated to a considerable extent as forage-plants, cattle being fed on their green herbage, although they are not suitable for drying as fodder. Among these are kale and cabbage, rape, &c.

In some parts of the world cattle are not unfrequently fed on the leaves of trees, as in the Himalayas, where the leaves of different species of *Aralia*, *Grewia*, elm, and oak are chiefly employed for this purpose, and are collected, dried, and stacked for winter fodder. In seasons of drought in India cattle are kept alive on the green leaves and pods of *Acacia* and *Inga dulcis*. See CLOVER, GRASSES, PASTURE, &c.

Fœtus, the term applied in Medicine to the mammalian embryo, especially in its more advanced stages. In the human subject we usually speak of the embryo at and after the end of the fourth month as a fœtus.

The weight and length of the fœtus at full term—nine months—vary within considerable limits. Observations on a very large number of cases have shown that this variety is related to several conditions—e.g. sex, race, number of previous pregnancies of the mother, &c. Male children are from 8 to 12 oz. heavier than female; children born in Britain are heavier by 3 or 4 oz. than those born in France, and first-born children are 4 to 6 oz. lighter than subsequent ones.

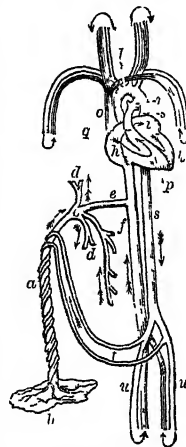

On an average the fœtus at birth weighs from 6½ to 9 lb. But a healthy child may weigh as little as 5 or 5½ lb., and cases are on record where the child has weighed 17½ and 18 lb. Children under 5 lb. weight at birth rarely live, and when they do are puny. The length of the fœtus is 17 to 21 inches, occasionally being as much as 24 inches.

There are certain points in which the fœtus at the full period differs anatomically from the child shortly after birth. The bony skeleton is very incomplete, cartilage occurring in the place of many bones. Indeed, complete ossification (viz. of the vertebrae) is not finished until about the twenty-fifth year, and the only bones completely ossified at birth are the minute ossicles of the ear. The difference between the fœtus and the child in this respect is, however, only one of degree.

During pregnancy a temporary organ, termed the placenta (popularly known as the after-birth, from its being thrown off shortly after the birth of the child), is developed on the inner wall of the uterus (see *b* in the figure). This organ is mainly composed of vessels, and there proceeds from it the structure known as the umbilical cord, *a*, in which lie the umbilical vein, which conveys arterial blood to the fœtus, and the two umbilical arteries, which return the blood to the placenta. This umbilical cord conveys these vessels to the umbilicus or navel. Before tracing the course of the blood through the fœtus, we must notice the chief anatomical peculiarities presented by the vascular or circulating system before birth.

(1) In the heart we find a communication between the two auricles by means of an opening termed the *foramen ovale*. (2) In the arterial system we have to notice first the *ductus arteriosus* (see *r* in the figure), which is a large communicating trunk between the pulmonary artery, *g*, and the descending aorta, *s*, *s*; and, secondly, the branches given off by the internal iliac arteries, which go under

the name of hypogastric as long as they are within the body of the fœtus, and of umbilical when they enter into the structure of the cord, are continued from the fœtus to the placenta, to which they return the blood which has circulated in the fetal system. (3) In the venous system there is a communication between the umbilical vein, *c*, and the inferior vena cava, *f*, called the *ductus venosus*, *e*.

The Fœtal Circulation.

mixed with the impure blood which is returned from the lower extremities and abdominal viscera, and is carried into the right auricle, *h*, and from thence, guided by the Eustachian valve (which is situated between the anterior margin of the inferior vena cava and the auriculo-ventricular orifice, and is of relatively large size in the fœtus), passes through the *foramen ovale*, into the left auricle, *i*. From the left auricle it passes into the left ventricle, *l*, and into the aorta, *m*, whence it is distributed by the carotid and subclavian arteries principally to the head and upper extremities, which thus receive comparatively pure blood. From the head and arms the impure blood is returned by the superior vena cava, *o*, to the right auricle; from the right auricle it is propelled, as in the adult, into the right ventricle, *k*, and from the right ventricle into the pulmonary artery. In the adult it would now pass through the lungs, and be oxygenised; but in the fœtus it passes through the *ductus arteriosus* into the commencement of the descending aorta, where it mixes with that portion of the pure blood which is not sent through the carotid and subclavian arteries. Some of this mixed blood is distributed by the external iliac arteries, *u*, to the lower extremities, while the remainder (probably the larger portion) is conveyed by the hypogastric or umbilical arteries, *t*, to the placenta.

From the above description we perceive: (1) That a considerable quantity of the pure blood from the placenta is at once distributed to the liver, which accounts for its large size at birth as compared with the other viscera. (2) That a double current meets in the right auricle, one stream, guided by the Eustachian valve, passing through the *foramen ovale* into the left auricle, the other through the auriculo-ventricular opening into the right ventricle. (3) That the comparatively pure blood sent to the head and arms, as contrasted with the impure blood sent to the lower extremities, causes the relatively greater development of the former organs, and prepares them for the functions they are called upon to perform; the development of the legs at birth being slight as compared with that of the head or arms.

Almost immediately after birth the *foramen ovale* becomes closed by a membranous layer, and the *ductus arteriosus* and *ductus venosus* degenerate into impervious fibrous cords. The lungs, previously to the act of inspiration, are dense and solid in structure, and of a deep-red colour, and lie far back in the chest. Their specific gravity is greater

than water, in which they (or portions of them) consequently sink, whereas lungs (or portions of lungs) that have respired float in that fluid.

Although nine months is the normal period of fetal development *in utero*, it is possible for a fetus to survive though born much within this period. When a child is born in a state of development sufficient to enable it to survive, it is said to be *viable*. A fetus born at $4\frac{1}{2}$ months may give evidence of life, such as movement of limbs, attempts at respiration, &c., but of course cannot survive, and hence is not viable. Several instances have been recorded in which the fetus survived after birth at $6\frac{1}{2}$ months. At seven months viability is established, and with reasonable care—particularly the employment of suitable 'incubators' or other means to keep the infant in an even warm temperature—a large proportion of children born at this time survive. Such children may become perfectly healthy and strong, both mentally and physically. It is said that Sir Isaac Newton was born at the seventh month. A child born after an abnormally prolonged gestation is apt to be so large that its birth is dangerous to itself and its mother. More especially does this apply to the head, which is apt to be not only too large, but too much ossified and so too hard to pass safely through the birth passages.

This article would be imperfect without a notice of the question—What constitutes live-birth? This is a point on which the most distinguished obstetric authorities have differed: some holding that where there is muscular movement there is life; while others maintain that where respiration has not been proved to have taken place the child was still-born. A scientific definition of live-birth is that it is 'the complete expulsion from the maternal birth-canals of a child which, whilst it loses pulsation in the cord, adds on to the other characters of ante-natal life the special sign of post-natal vitality, viz. pulmonary respiration.'

In English law, however, as it at present stands, respiration is not necessary to establish live-birth (cf. *Brook v. Kellock*, 1861), and the same holds good in France and the United States. In Scotland, on the other hand, the law requires that a child shall not only have breathed, but actually cried; and accordingly a child which was born, breathed, and died of convulsions at the end of half-an-hour was declared to have been born dead. See EMBRYOLOGY, and other articles cited there; also GESTATION, PREGNANCY.

Fog, or MIST. Water vapour is always present in the atmosphere, and it condenses either as rain, mist, or fog when the state of saturation is reached. In some cases dust-particles condense moisture from non-saturated air, and this produces what is known as a *dry fog*. Condensation of moisture takes place on a drop more readily the larger it is (see CAPILLARITY), and experimental proof was given by Dr John Aitken in support of the theory that no condensation can occur without the presence of a nucleus. Such a nucleus is furnished by the visible or invisible dust-particles in the atmosphere. The amount of vapour present and the number and size of the dust-particles in part determine whether fog, mist, or rain will be formed, under given conditions of temperature and pressure; but the gathering of moisture into drops sufficiently large to fall as rain seems not to depend merely on the number and size of the particles on which condensation occurs. When a stratum of warm, dusty air gets cooled, a fog may be produced. The great amount of smoke-particles and dust-particles present in the air of large towns furnishes the conditions, in certain states of weather, that give rise to the intense fogs often prevalent in

large cities. A morning fog disappears as the temperature rises, because of evaporation of the moisture from the nuclei. A fog is often produced in the evening over the surface of water or moist ground, because the air is sufficiently cold for condensation of vapour to occur. The fogs on the coasts of Nova Scotia and other places are caused by currents of warm air moving over cold water; so also the fogs caused on the coasts of Oregon and California by west and north-west winds. On the outskirts of an anti-cyclone fogs of immense breadth sometimes stretch for hundreds of miles lengthwise. Aitken pointed out that dust-particles are probably efficient in the production of fog or rain in another way besides acting as nuclei. He believes that dust is a good absorber, and therefore a good radiator, of heat; for he has shown that, on equally clear days, the sun's heat is strong if the number of particles per unit volume of the atmosphere is small, but is weak if the number is large. Hence, when the sun's rays are withdrawn, the air surrounding the particles is rapidly cooled, and its moisture condenses.

Clouds, whether of fog, mist, or rain, though apparently suspended in the air, are in reality falling with extreme slowness. The force which causes drops to fall is their own weight, which is proportional to the cube of their diameter. The force acting upwards is the resistance of the air, which is proportional to the diameter. Hence, if the diameter of a drop becomes $\frac{1}{10}$ of its original value, the resistance is reduced to $\frac{1}{10}$ only of its value, while the weight becomes $\frac{1}{1000}$ of what it was before, and so the drop falls far more slowly.

One of the worst fogs on record, alike for its density and protractedness, occurred in London from the beginning of November 1879 to the following February. The deaths for the six weeks ending February 21st were 1730, 1900, 2200, 3376, 2495, and 1016, the deaths in the fourth week being thus nearly double those of the first. Of all diseases the deaths from asthma were most directly influenced in fatality by the fog. In the first three weeks of 1880, when London was largely cleared of fog, the deaths fell 30 per cent. below the average; but in the end of January, when the fog again became severe, the deaths rose to 43 per cent. above the average. Bronchitis, pneumonia, pleurisy, other lung diseases, and whooping-cough, though not showing so strict an obedience to the varying density and persistence of the fog, rose to a much greater fatality, the death-rate from bronchitis rising to 331 per cent. and whooping-cough to 231 per cent. respectively above the averages of these diseases. Fogs are worst in the low-lying districts which are on the lee-side of the city, with respect to the direction of the light drift of the wind at the time, and least felt in the higher districts on the windward-side, the amount of suffering and number of deaths being proportioned to the density and persistence of the fog.

Fogazzaro, ANTONIO (1842-1911), an accomplished Italian poet, novelist, essayist, and writer on various themes, was born at Vicenza, studied law at Turin, and became a follower of Giacomo Zanella. He won fame by a narrative poem, *Miranda* (1870), and by *Valsolda* (1876) and *Profumo*, volumes of lyrics. Among his novels—many of which have been translated—are *Malombra* (1882), *Daniele Cortis* (1887), *Eva* (1892), *Alla Vigilia* (1896), *Il Piccolo Mondo Antico*, *Il Piccolo Mondo Moderno*, and *Il Santo* (1905). This work, depicting modernism, was placed on the *Index Expurgatorius*. Fogazzaro submitted, lost such sympathy as he had had with the extreme modernists, and in *Leila* (1910) modified the position that had given offence to the Church. See *Life by Gallarati-Scotti* (1920; Eng. trans. 1922).

Foggia, capital of an Italian province, is situated in a fertile district 76 miles NW. of Bari, with a cathedral, commenced in the Norman style in 1172, but partially destroyed by an earthquake in 1731, and afterwards rebuilt in a different style. Foggia, which is the most important mart in Apulia, was a favourite residence of the Emperor Frederick II. Pop. 90,000.

Fog-signals, audible warnings used on board ships, on the sea-coast, or on railways, during fogs and mists, or at any other time when lights or ordinary daylight-signals are not available (see **SIGNALLING**). An international code of fog-signals, recognised since 1861 and revised in 1897, is used at sea all the world over; the prescribed signals in vessels under way being made in steamers by a steam-whistle or siren, in sailing-vessels and vessels being towed by a mechanical fog-horn, and in all vessels at anchor by a bell. They are as follows: In fog, mist, falling snow, or heavy rain-storms, whether by day or night, a steam-vessel having way upon her shall sound at intervals of not more than two minutes a prolonged blast. A steam-vessel under way, but stopped and having no way upon her, shall sound at intervals of not more than two minutes two prolonged blasts, with an interval of about one second between them. A sailing-vessel under way shall sound at intervals of not more than one minute, when on the starboard tack one blast, when on the port tack two blasts, and when with the wind abaft the beam three blasts. A vessel when at anchor shall, at intervals of not more than one minute, ring the bell rapidly for about five seconds. A vessel when towing, a vessel laying or picking up a telegraph cable, and a vessel under way which is unable to get out of the way of an approaching vessel through being not under command or unable to manoeuvre as required by these rules, shall, instead of the prescribed signals, at intervals of not more than two minutes, sound three blasts in succession—one prolonged blast followed by two short blasts. A vessel towed may give this signal, and she shall not give any other. Sailing-vessels and boats of less than twenty tons gross tonnage shall not be obliged to give the above-mentioned signals, but if they do not they shall make some other efficient sound-signal at intervals of not more than one minute. There are fog-signals on light-ships and at shore stations on the coasts of all civilised nations; these are usually either horns (reed or siren) or explosives (see articles **SIREN** and **LIGHTHOUSE**); but the best of these are not to be trusted to implicitly in fog—they may be heard, *but may not*. The natural law governing the aberrations of signals in fog is not understood; the mariner who expects to hear a shore fog-signal should, if he does not hear it, at once have recourse to the lead.

The fog-signals used on railways are small cases charged with detonating powder, and laid upon the rails. They explode loudly when the wheel of an advancing train comes upon them. They are used not merely in fogs, but in all cases of danger from obstruction of the line, or in other cases of urgency when a train has to be stopped without delay. Station-masters and railway police are furnished with them.

Föhn. See **WIND**.

Föhr, a fertile island in the North Sea, off the west coast of Sleswick, to which it belongs. Area, 28 sq. m.; the inhabitants, Frisians by race, are principally engaged in fishing and fowling. The chief town is Wyk.

Foil (Lat. *folium*, 'a leaf') consists of metal reduced to very thin sheets, intermediate between the extremely thin leaf metal, such as gold and silver leaf, and sheet metal. There are two dis-

tinct classes of foil in common use—the foil which in tenuity approaches leaf metal, and the much stouter tinsel foil used by jewellers, and for theatrical ornaments, &c.

Tinfoil is made by rolling bars of tin down to fine sheets, which are further attenuated by being laid in piles and beaten with a wooden mallet. Formerly tinfoil was very largely used for the 'silvering' of mirrors, by amalgamation with mercury; but that process is now little employed (see **MIRROR**). The chief consumption of tinfoil is now in connection with the wrapping up of chocolate and other confectionery, and of tobacco and other products which must be kept from drying in the air. It is also largely used for lining small boxes and cases, and in the preparation of Leyden jars and other electrical apparatus.

The bright foil used by jewellers and for theatrical and other ornaments, under the name of 'tinsel,' is made of copper, tin, tinned copper, or silvered copper. The last is now chiefly used by jewellers. The metal is rolled in a flattening mill, and the requisite brilliancy of surface is produced by finishing between burnished rollers and polishing. The various colours are produced by coating the white metal with transparent colours mixed in isinglass size. A similar varnish without colour is laid over the white foil, to prevent tarnishing. The socket or setting in which a stone or paste is mounted is lined with the foil, which, by reflecting from the internal facets the light that passes through the stone, adds considerably to its brilliancy. The natural colours of real stones are sometimes heightened or modified by coloured foil, and factitious colours are thus given to the glass or 'paste,' as it is called, of which spurious precious stones are made.

Foil. See **FENCING**.

Foix, capital of the French department of Ariège, lies in a Pyrenean valley, 44 miles S. of Toulouse by rail. Of the ancient castle of the counts of Foix (1362) there remain only three towers, all dating anterior to the 15th century. The town has iron and steel works. Pop. 6000.

Foix, an old French family, which took the title of count from the district of Foix (now the department of Ariège), in the south of France. The first who bore the title was Roger, who died in 1064. Roger Raymond accompanied King Philip Augustus to Palestine and distinguished himself at the taking of Acre. Afterwards, on his becoming an adherent of the Albigenses, his estates were confiscated by Simon de Montfort. He was a patron of the Provençal poets, and died in 1223. The next succeeding counts held their lands of the king of France; they were principally engaged in waging a feud against the House of Armagnac, and in fighting for the French king in the English wars. Gaston III. (1331-91), called, on account of the beauty of his person, *Phœbus*, was noted for his knightly love of splendour and military prowess. For his assistance to the king against the English in 1345, he was made governor of Languedoc and Gascony. In 1356 he took part in a crusade against the heathen Letts of Prussia, and in 1358 rescued certain members of the royal family out of the hands of the Jacquerie insurgents. On being supplanted in the governorship of Languedoc by the Duc de Berri, Gaston maintained his position by force of arms, and defeated the duke at Revel. He left a work on hunting, *Miroir de Phœbus*, whose bombastic style became a byword (*faire du Phœbus*). After his death without children, in 1391, the estates and title went to a collateral branch of the family. Gaston IV. rendered good service to Charles VII. in his wars against England. In 1455 his father-in-law, John II., king of Navarre, named

him his successor, and the French king invested him with the seignior of Carcassonne and the countships of Roussillon and Cerdagne. He died in 1472, when the family possessions were again divided. His grandson, Gaston (1489-1512), whose mother was Marie d'Orléans, sister of Louis XII. of France, received from his uncle the title of Duc de Nemours in 1505. In the Italian wars Gaston displayed such brilliant genius and bravery as to earn the title of 'Thunderbolt of Italy.' He twice overthrew the Swiss, at Como and Milan (1511); chased the papal troops from Bologna; seized Brescia from the Venetians; and won the battle of Ravenna over the Spaniards, 11th April 1512, in which, however, he fell, at the early age of twenty-three. On his death the estates and title went to the king of Navarre. Finally Henry IV. of Navarre attached the county of Foix to the French crown.

Fokshani. See FOCŞANI.

Folcland, or FOLKLAND, used to be explained as the public land of the nation in old English times, what remained to the nation over and above what was possessed by individuals, families, or townships. It was under the control of the king and witan, and, after England was consolidated into one kingdom, was very large. But it was always diminishing, portions being granted to individuals for services rendered, and to the church, &c.; the land so alienated from the public became Bôcland (q.v.). Sir P. Vinogradoff, however, showed strong reasons for believing that folkland was rather land held by folkright, or common law, while bookland was held by charter. See LAND LAWS.

Földvar, or DUNA-FOLDVAR, a town of Hungary, and a steamboat station on the Danube, 48 miles S. of Budapest, with sturgeon-fishery, vineyards, and manufacture of matches; pop. 15,000.

Foley, JOHN HENRY, R.A., sculptor, was born in Dublin, 24th May 1818, became a student of the Royal Academy in 1835, and first exhibited in 1839. His 'Ino and Bacoelus' (1840) attracted much notice, and was followed by a succession of admirable classical and ideal works, including 'A Youth at a Stream,' 'Caractacus,' and several excellent subjects from Shakespeare. The most noteworthy feature of his work, however, was his careful and artistic execution of his statues and busts, which included the Hampden and Selden figures in St Stephen's Hall, Westminster; Goldsmith, Burke, and O'Connell, in Dublin; and the equestrian statues of Lord Hardinge and Sir James Outram, for India, which rank among the finest equestrian sculptures of modern times. The statue of the Prince Consort for the Albert Memorial is also Foley's work. He died 27th August 1874, and was buried in St Paul's Cathedral.

Fol'gore, an Italian poet who flourished at the end of the 13th century, the dates of whose birth and death and the incidents of whose life are unknown. He wrote a number of sonnets, all of which have been translated into English by Dante Rossetti and J. A. Symonds. Their poetic merit is far from contemptible, and they are particularly interesting from the vivid light which they throw on Italian society. Their prevailing tone is one of refined epicureanism, and their style is mainly remarkable for affluence of imagery. 'Every line,' says Symonds, 'presents a picture, and each picture has the charm of a miniature fancifully drawn and brightly coloured on a missal marge.' See Rossetti's *Dante and his Circle* (1874), and Navone's *Le Rime di Folgore* (Bologna, 1880).

Foliation, a term restricted by Darwin, and subsequently by geologists, to the alternating and more or less parallel layers or folia of different mineralogical nature, of which the crystalline schists are composed. It differs from Cleavage (q.v.),

which is applied to certain superinduced divisional planes that render a rock fissile; and from lamination, in which the planes of separation in a rock are the result of deposition in successive layers. The folia of a schistose rock may be composed of only one mineral, but most commonly they consist of two or more; they are conspicuously lenticular, thickening and thinning out, and reappearing after an interval on the same or a different plane. These alternately lenticular folia are usually more or less closely welded or felted into each other, so that they are not readily separable; and they frequently present the appearance of being puckered or crumpled. The crystalline texture and the foliated character of the schists distinguish them at once from any ordinary bedded 'fragmental rock.'

Foligno, a town of Central Italy, on the Topino, 25 miles SE. of Perugia. The town has a modern appearance, and possesses a cathedral and several churches. Tanning, paper-making, the manufacture of sugar confectionery, and the cultivation of the vine and of silk are carried on. The town was destroyed by the people of Perugia in 1281, and in 1833 it suffered severely from an earthquake. In 1439 it became subject to the pope. Pop. 30,000.

Folkes, MARTIN, English antiquary, born in London on 29th October 1690, died on 28th June 1754, is known by two books on English coins—*A Table of English Gold Coins* (1736), and *A Table of English Silver Coins* (1745). He was a member of the Royal Society (president in 1741), of the Society of Antiquaries (president in 1750), and of the Paris Academy of Sciences.

Folkestone, a municipal borough, seaport, and bathing-place of England, on the coast of Kent, 7 miles WSW. of Dover, stands on uneven ground at the foot of a range of hills and on their slopes, the oldest part lying in a narrow valley, crossed by a fine railway viaduct. The town has rapidly extended and improved since the opening of the South-Eastern Railway, and of a daily service of steam-packets to Boulogne. Pop. (1881) 18,816; (1921) 37,571. Folkestone is included in the parliamentary borough of Hythe. The harbour is much used by boats employed in the herring and mackerel fisheries. In the vicinity are extensive Roman remains. Here Harvey, the discoverer of the circulation of the blood, was born in 1578.

Folkland. See FOLCLAND.

Folklore, a term first suggested by W. J. Thoms in 1846 (*Athenæum*, August 22, under his well-known signature 'Ambrose Merton') to designate what was then for the first time becoming a subject of wide popular interest, considered as a department of the study of antiquities or archaeology, and embracing everything that related to ancient observances and customs, to the notions, beliefs, traditions, superstitions, and prejudices of the common people. Folklore, as understood by Thoms, had indeed been observed and noted by countless writers from the Father of History downwards; the *Gentleman's Magazine* in the 18th century, and, in the 19th, his own well-known journal *Notes and Queries* (instituted 1851) being invaluable repositories of such observed facts; but it was not till after the beginning of the 19th century that the value of folklore for the elucidation of the social history of mankind had become apparent to thinkers, and its systematic study been seriously begun. Nor had there been wanting special collections of detached facts, very varied in quality but all of precious value now, by curious antiquaries, as John Aubrey in his *Miscellanies* (1696), or by speculative original thinkers, as Sir Thomas Browne in his *Pseudodoxia Epidemica* (1646). The former discussed in a gossiping manner such matters as omens, dreams, corpse candles, and

second-sight; and another work by the same credulous author, *Remains of Gentilisme and Judaisme* (ed. by James Britten, 1881), 'did not disdain to quote,' a multitude of ancient customs which would otherwise have been forgotten, and which have proved to be a precious mine for later and more scientific students. The Rev. Henry Bourne published at Newcastle in 1725 his *Antiquitates Vulgares, or the Antiquities of the Common People*, valuable chiefly for its record of old popular customs connected with the feasts of the church; and at the same city John Brand published in 1777 the first edition of his famous *Observations on the Popular Antiquities of Great Britain*. This work, as subsequently enlarged by himself, partly from the stores of miscellaneous facts of folklore collected in Sinclair's *Statistical Account of Scotland* (1791-95), and thoroughly revised by Sir Henry Ellis in 1813, ill arranged as it is, remains the richest of such storehouses of folklore as formerly—of materials for folklore as now—understood. Of other books containing similar records more or less valuable of detached facts, it may be enough here to name Strutt's *Sports and Pastimes of the People of England* (1801); Hone's *Every Day Book* (1826-27), *Table Book* (1827-28), and *Year Book* (1829); and Chambers's *Book of Days* (1863).

Meantime the reawakening to natural poetry, and to the beauty of free emotional expression in literature, which lay at the foundation of what it is usual to call Romanticism, had already begun even in the 18th century, and the publication of Percy's *Reliques of Ancient English Poetry* (1765) had given a powerful impulse to Scott and others in England, to Herder, and to Arnim and Brentano in Germany, who found lying to hand a rich wealth of traditional poetry, the poetic value of which they fortunately had the eyes to see. But the study of folk-songs really began with Scott's *Minstrelsy of the Scottish Border* (1802-3). It was perhaps an advantage rather than a disadvantage that the first worker in this new field was but the folklorist unawares and mere great poet and romancer of genius that he was; for our folk-poetry would never have enriched and permanently influenced all later English literature but for its own intrinsic and genuine poetic quality, any more than our detached folklore facts would ever have risen above the dignity of the whimsical pastime of an idle hour but for their inherent though unsuspected faculty for throwing light backwards upon the history of human civilisation. And it is fortunate for us that we have had before us a succession of antiquarian students with curiosity enough to note and preserve things strange for their own sakes—facts merely half-understood or entirely misunderstood, but yet to be co-ordinated and systematised by later ages after a really scientific spirit had been born. The spread of book-learning and the inevitable diffusion of rationalistic ideas, the levelling of the ancient social distinctions, and the creation of totally new industrial conditions transplanting the people from the customs and ancient habitations of their fathers have stopped short the current of popular belief which has flowed traditionally down in undisturbed but ever-widening stream from the mists of obscure antiquity, and turned its waters, rich with the fertilising faculty of imagination, to overflow new fields within the vast vistas of science. Popular traditions began to be valued duly just as they began to decline and disappear; but fortunately a plentiful crop had been gathered and put into writing beyond the risk of oblivion before the growing disfavour for everything supernatural but religion itself, and the impatience of anything beyond the range of the practical and the profitable, had stripped our

people of everything they had received from their fathers.

Yet the task of the folklore-collector even in England is not at an end, though the conditions under which he has to work are materially altered; for countless ancient notions still survive, although in strangely altered form, and although our citizens fondly imagine in all the pride natural to a little learning that all old things have been put away, and that all things have become new. The most consciously rational mind is ever unconsciously swayed by impulses and habitudes, the origins of which are so obscure as to be entirely unknown and even unsuspected, but which weigh irresistibly though imperceptibly upon it. The scientific student of folklore co-ordinates the results of observation and experience, and builds them into a unity. But he must not forget that to his generation belongs mainly the task of accumulating these materials, and that the building itself must be left to the larger generalisations of future ages. Meantime such works as Sir E. B. Tylor's *Primitive Culture* (1871), from a wide comparison of the essential identities and analogies between European and savage customs and superstitions, and Sir G. L. Gomme's *Folklore Relics of Early Village Life* (1883), from a close observation of the affinities of our own village and homestead customs with those of other lands, have shown us what large and significant constructive results may already be attained with the evidence we possess. It was the peculiar merit of Sir E. B. Tylor to have demonstrated the evidential value of such *survivals* of more or less savage earlier states of society as still exist among us to reflect light upon the past. 'Survival in culture, placing all along the course of advancing civilisation way-marks full of meaning to those who can decipher their signs, even now sets up in our midst primeval monuments of barbaric thought and life. Its investigation tells strongly in favour of the view that the European may find among the Greenlanders or Maoris many a trait for reconstructing the picture of his own primitive ancestors.' Sir J. G. Frazer's encyclopædic *Golden Bough* is formally a working-out of the relations of one such survival among the Romans.

Just as the science of archaeology has been laboriously built up out of the relics of old peoples that have been brought to light, so the task of the folklorist is to construct the philosophy of primitive man from its still-surviving or recorded relics. These linger longest among the least progressive peoples, and it is in their superstitions and stories, whether in their native irrationality or as rationalised by a shallow philosophy, that the student will find the richest and most plentiful materials. He must not confine his pursuit of analogies to the experiences of merely Aryan or yet Old-World peoples, for in the survivals to be seen in the religious rituals and ceremonial traditions of the most civilised peoples he will find things absolutely identical with the beliefs and customs of present-day savages in Africa or the South Sea Islands. Neither identity of race, nor community of origin, nor conscious borrowing need be postulated if we accept the theory that the minds of men at parallel levels of culture are everywhere substantially the same, and develop naturally along the same lines in that gradual progress upwards, which is ever in movement, though ever differing in degree. The fundamental bases of popular beliefs then are everywhere the same: what is due to the particular race is the particular development of the belief. Gods, who are mere magnified men, capable like them of being influenced by magical powers, and not more superior than men themselves to trans-

formation into human and bestial forms; spiritual existences which pervade all nature, animate and inanimate alike, adding the human attribute of personality to all visible objects; ghost-souls surviving in shadowy form beyond the grave—these are the fundamental assumptions of all mythologies, and the essential foundations of the religion of all men. What race adds is the particular poetical form and colour with which the human imagination clothes its shadows. Andrew Lang, by his felicitous wealth of illustration, made this explanation the accepted working hypothesis of most mythologists of his time, who are often grouped together as forming the anthropological school. Since his death much ground has been gained by other theories. The Freudians have explained myths very much as they have Dreams (q.v.). The 'historical school' has been traced back to Friedrich Ratzel in the eighties of the 19th century, and to Drs Ankermann and Graebner in the 20th. In England it arose independently. Dr W. H. R. Rivers in his *History of Melanesian Society* (1914), a model of scientific method, showed that certain elements in the culture of the islanders are linked together in a way that enables the student to divide the whole into strata. These strata he believed to have been superposed one upon another by a succession of migrations. The interactions and adjustments of different cultures thus brought together are also important. 'The widespread similarities of culture are, it is held, due in the main, if not wholly, to the spread of customs and institutions from some centre in which local conditions favoured their development.' Such a centre Professor Elliot Smith finds in Egypt, whence Professor Perry and others seek to trace the world-wide diffusion of culture. It is not contended that the Egyptians colonised America, for instance; but that the building up of civilisation in response to local conditions can be traced in the history of Egypt, that Egypt passed on much to Crete and Babylonia, Babylonia to India, and so on, until not only in these regions, but even in the Pacific islands and America, we find the decayed remains of a culture that had no firm root in the people's own past. Much importance is attached to the search for gold and pearls, the setting up of megalithic monuments, irrigation, mummification, and a complex of customs and beliefs associated with these.

The first two generations of folklorists made a vast contribution to the science from the evidence offered within the Indo-European family; the third extended its borders to embrace the native Australians, the Zulus, Hottentots, Maoris, South Sea Islanders, Red Indians, and Eskimo; and extended the library of folklore and folk-tales to thousands of volumes.

First in importance of these is still the earliest, the *Kinder- und Haus-Märchen* (1812-14) of the brothers Grimm. The stories in the first two volumes of this wonderful work were collected during thirteen years from the lips of people living in Hesse and Hanau, many from a cowherd's wife with a special gift of story-telling. Wilhelm Grimm, writing in 1850, says: 'How unique was our collection when it first appeared, and what a rich harvest has sprung up since! At that time people smiled indulgently when we asserted that thoughts and intuitions were preserved in these stories, the origin of which was to be sought for in the darkness of antiquity. Now this is hardly ever denied. Stories of this kind are sought for with full recognition of their scientific value, and with a dread of altering any part of their contents, whereas formerly they were only regarded as worthless amusements of fancy which might be manipulated at will.' W. Grimm's *Deutsche Mytho-*

logie (1835) is still unequalled in the range of its erudition and in the systematic thoroughness with which the mythology and superstitions of the ancient Teutons are traced back to the dawn of direct evidence and downwards in decay and diminution to the popular tales, traditions, and phrases in which they still unconsciously survive. These two works of Grimm created a school, whose abundant labours later folklorists have entered into, while they have enlarged the horizon of the science, because the stamp of soundness and sufficiency so far as it goes is impressed on all the work of Grimm and his successors, of whom, in Germany, the most eminent were Kuhn, Mannhardt, J. W. Wolf, and W. Schwatz.

Elsewhere, Casti  n and Lonnrot devoted themselves to Finnish mythology; Asbj  rnsen and Moe collected the Norse popular tales; Schi  ner and Julg, those of the Mongolians and Tatars; Hyt  n-Cavallius and George Stephens, those of Sweden; Afanasief, those of Russia; Hattich, of Transylvania; Kreuzwald, of Esthonia; Von Hahn and B. Schmidt, of Greece and Albania; Arnason, of Iceland; Rink, of the Eskimo; Bleek, of the Hottentots; Calloway, of the Zulus; J. F. Campbell, of the West Highlands of Scotland. The study of these tales involved the study of the customs imbedded in them, and ere long a plentiful crop of books appeared devoted to the preservation of popular proverbs, customs, rhymed riddles, and the like, among which a place of distinction is due to the *Fairy Legends and Traditions of the South of Ireland* (1825), by T. Crofton Croker; the *Popular Rhymes of Scotland* (1826) of Robert Chambers; *The Nursery Rhymes of England* (1842) and the *Popular Rhymes and Nursery Tales* (1849) of Halliwell-Phillipps; and that not merely for the early date of their issue, but for their own intrinsic merits also. The great development of oriental studies that marked the 19th century opened up to the West through literary channels those vast treasures of Eastern story from which many believe, as will be seen, that all our own traditional folk-tales were originally drawn in ancient ages. Max Muller's essays revealed to Englishmen a new world of undreamt-of affinities, and the combined charm of their literary grace, wide learning, and rare powers of exposition converted every reader to a theory which was only slowly displaced. Since then the study of folklore has become fashionable, indeed almost an article of patriotism, and societies have been formed in most countries to further its study. Of these the most important is still the Folklore Society of England, established in 1878, with a sufficiently wide programme, 'having for its object the preservation and publication of popular traditions, legendary ballads, local proverbial sayings, superstitions and old customs (British and foreign), and all subjects relating to them.' It numbers within its ranks most of the working folklorists of England, and has through its official organ, the *Folklore Record*, at first monthly, then quarterly as the *Folklore Journal*, later incorporated with *Folklore*, made numberless contributions of the first importance to the science; while it has also distributed valuable special treatises to its members.

The Folklore Society divides up the subject thus: I. *Beliefs and practices* relating to (1) the earth and the sky, (2) the vegetable world, (3) the animal world, (4) human beings, (5) things made by man, (6) the soul and another life, (7) superhuman beings—gods, godlings, and others, (8) omens and divination, (9) the magic art, (10) disease and leechcraft. II. *Customs*: (1) Social and political institutions, (2) rites of individual life, (3) occupations and industries, (4) calendar fasts and festivals, (5) games, sports, and pastimes. III. *Stories, songs, and sayings*: (1) Stories (a) told as true,

(b) told for amusement, (2) songs and ballads, (3) proverbs and riddles, (4) proverbial rhymes and local sayings.

Folksongs, Ballads, Counting-out Rhymes, &c.—The reader has already seen the important part that belongs to popular folksongs or Volkslieder in the scheme of folklore, and he will find this department already treated with some fullness in this Encyclopædia under the head of BALLADS. These belong also to literature proper, from their intrinsic poetic content, and from the important influence they have exerted upon more cultured poetry. The patriot whose survey ends with his own shores and the mere man-of-letters alike claim them as falling within their province, in so far as they are national history and literature as well as tradition. Yet these may be correlated with the traditional folk-poetry of other races no less than folk-tales, and we have a splendid example of this in Professor Child's treatment of our *English and Scottish Popular Ballads* (5 parts, 1882-88)—the best edition of a body of popular poetry available to the student.

Much attention has been paid to children's rhymes and formulas of play, which have been found to be handed down from immemorial antiquity, and to reflect with strange persistency the life and even the religion of long past times. The games and rhymes of American children of to-day agree not only with those of Old England, but with those of Germany, France, Italy, and Sweden. Those doggerel rhymes of unmeaning jingling words for 'counting out' live with startling persistency, and some idea of their venerable antiquity may be gathered from the history of the so-called 'Anglo-Cymric score,' a corrupted form of the Welsh numerals up to twenty, still used in Cumberland for counting sheep, but used by children in many parts of Great Britain, and more strangely still, even in America, where it has often been supposed to be of Indian origin. Of these jingles as many as 800 specimens were collected by a single editor (H. Carrington Bolton, 1888).

Folk-tales, their Content, Origin, and Diffusion.—These, the *Volksmärchen* of the Germans, the *Contes populaires* of the French, are properly popular tales handed down by oral tradition from remote antiquity. Besides this continuous life they have at various times been lifted into literature, and again reacted in new forms upon purely traditional lore, thereby complicating enormously the problems to be solved. Thus, in the *Odyssey* and *Rig-Veda* we find distinct traces of veiled and degraded folk-tales; while in the *Panchatantra*, *Hitopadesa*, *Kalilah wa Dimnah*, and *Somadeva's Katha Sarit Sāgara*, the *Thousand and One Nights*, the *Gesta Romanorum*, the *Disciplina Clericalis*, the *Tredecim piacevoli notti* (1550) of Straparola, Basile's *Pentameron* (1637), the old French fabliaux, the *Decameron* of Boccaccio, and Chaucer's *Canterbury Tales*, we find many actual folk-tales, more or less disguised by artistic processes of elaboration and refinement. These stories, from whatever sources originally derived, exercised a profound influence upon both Eastern and Western literature. In 1697 Perrault published his famous *Histoires ou Contes du Temps Passé*, seven stories undoubtedly written down substantially in their traditional shape. They created a fashion, and in imitation of them literary fairy tales were steadily produced throughout the 18th century, as may be seen in the voluminous *Cabinet de Fées*. But the beginning of real science was, as has been seen, the *Kinder- und Haus-Märchen* of the brothers Grimm. Since their time thousands of stories have been printed from all quarters of the globe.

The Grimms early found a startling similarity in the substance of these stories, and it only

remained for later workers to discover the same identities when the comparison was extended far beyond the range of Aryan affinities. It was found that certain incidents, plots, and characteristics occurred everywhere—as the ill-treatment of the youngest son or daughter, who is eventually successful, and is often the heir; the substitution of a false bride for the true; the abduction of a bride by a youthful hero, and the pursuit by her giant (or supernatural) father, who is outwitted by cunning; a supernatural husband or wife, who is for some cause obliged to abandon a human mate; forbidden chambers, and the disasters that follow from their being opened; descents into the world of gloom, and the danger of eating there; husband and wife forbidden to see each other or name each other's names; the souls of the dead entering animal forms; and the interchange of kindly offices, as if on equal terms, between men and beasts. Again, the incidents are usually unnatural and irrational, completely traversing ordinary human experiences: thus, magical transformations, cannibalism, incest, beasts and men intermarrying, women bringing forth beasts and *vice versa*, and inanimate things obeying incantations and speaking like men are perfectly familiar occurrences. An attempt was made by Von Hahn, in the introduction to his *Griechische und Albanesische Märchen* (1864), to construct a scheme for classifying folk-tales so as to facilitate comparison, and this idea was developed by Baring-Gould, Alfred Nutt, and other folklorists, until at length it was adopted by the Folklore Society (Fourth Report, June 1882). A series of schedules was prepared for systematic tabulation, the following points being especially observed: (1) The fixing of a generic title for each story, and the abolition of the variant titles of the same story which now obtain in different collections; (2) the determination of a common terminology for the study of stories and for each description of story; (3) the determination of a common terminology for each story-incident; (4) the compilation of an index of story-incidents; (5) the tabulation of all stories in printed collections upon a common recognised plan. The Society also originated a similar analysis of customs.

The time is not yet ripe for any satisfactory answer to the sphinx-like riddle of the origin and manner of diffusion of folk-tales; here it must suffice to state briefly the chief attempts at an answer hitherto offered. The first theory, sanctioned by the august authority of the Grimms, and maintained by Max Müller, Von Hahn, Dasent, and, with more zeal than discretion, by Cox and De Gubernatis, is that popular tales form a part of the mythology of the Aryan peoples, and were carried by them westwards at the primeval dispersion. Some consider them the *detritus* of the saga and the epic, others again as the original elements by a reconstruction and artistic elaboration of which the epics and sagas were formed. The next contribution of first importance was made by Benfey, in the masterly introduction to his translation of the *Panchatantra* (1859). His contention was that the popular tales were carried to Europe from India within historical times, and diffused chiefly through literary channels, such as translations of Eastern story-books and the like. A few special sources were the fables connected with the names of Æsop or of Bidpai; the *Panchatantra*, especially the parent of tales; and *Syntipas*—in other versions called the *Book of the Seven Wise Masters*—more closely connected with novel literature. Among the more important media of communication may be named the wandering and trading Jews, the Moors in Spain, and the Crusaders in their intercourse with the Moslems in the East and with the orientalised Greeks of Byzantium. Dr Gaster (*Ilchester Lectures*, 1887)

made the old Slavonian religious literature the parent of the mediæval and imaginative apocryphal literature, the romances and epics, and the didactic fables; and argued that oral folklore arose out of this written literature, the traces of which may be found in saga and romance, in religious and epic poems, in riddles and tales, and even in popular beliefs, customs, and habits. The ultimate common origin of all these was the East, of which not only the religion but the profane literature reached the Slavonic peoples through the medium of Byzantium—the open gateway of the East. He postulated a previous literary period, and affirmed that not the legends alone, as now known to us, but also the fairy-tales, and even amulets and spells, were almost unknown in Europe before the 10th century. Mr Clouston and M. Cosquin follow Benfey with greater or less modifications; and Mr F. Hindes Groome made the striking suggestion (*The National Review*, July 1888) that one main channel of communication may well have been that ubiquitous, wandering, and specially gifted oriental race, the Gypsies. M. Cosquin argues that if the Aryan race before its dispersion preserved the myths only in their earliest germinal form, after the separate branches had lost touch of one another it would have been impossible for the final forms of the myths—the household tales as we have them now—to resemble each other so closely as they do. While admitting that the same ideas and situations are afloat wherever men exist at the same stage of culture, he refuses to allow that independent parallel or identical combinations are possible without conscious borrowing. What makes a story, properly speaking, is not the ideas which enter into it, such as speaking beasts, transformations, objects of magic, and the like, but rather the combination of the same, which is usually a thing entirely arbitrary; and it is impossible to believe, according to M. Cosquin, that identical successions and combinations of incidents can occur without transmission by some means or other. He argues that the combinations in European folk-tales are Indian, nay, Buddhistic; consequently they must have been transmitted within the historical period from India.

Some attribute the origin of all human culture to Egypt, but of course it might be said that ideas and combinations of ideas may have been carried from Egypt to India, which there ripened into fruit, and were scores of generations afterwards carried back again to the West.

The theory of Lang and the anthropological school has already been stated substantially in the foregoing pages. It makes the spontaneous generation of similar ideas, incidents, and arrangements of these, under the same physical conditions, and at parallel levels in culture, the most important element in the manufacture of folk-tales. Popular tales are thus 'kaleidoscopic arrangements of comparatively few situations and incidents, which again are naturally devised by the early fancy.' At the same time it admits that the process of borrowing has also gone on, and that stories once invented may have been carried from people to people by daring merchants, captured alien wives, and slaves bought or carried off by violence.

As in other departments of folklore, the pendulum has swung again from 'spontaneous and independent generation' to 'diffusion from one centre.' Thus Professor W. R. Halliday (*Folklore*, xxiv. No. 2, 1923) gives (undogmatically) an explanation of European folk-tales not very different from Cosquin's. While pointing to signs of a certain current from west to east as well as from east to west, and suggesting various hypothetical centres of distribution—Celtic, Teutonic, Slavonic, Arabo-Persian, Indian—he tends to the opinion that these tales took their present form between the 9th and

13th centuries, when by way of Turkey and North Africa a victorious invasion of oriental stories took place. To the diffusion of Beast-fables (q.v.), however, a much earlier date is assigned. They probably came to Greece in classical times from the East.

See the articles on ANIMISM, BALLADS, BEAST-FABLES, CHAP-BOOKS, DEMONOLOGY, DIVINATION, FABLES, FAMILIAUX, FAMILY, KIN, MAGIC, MYTHOLOGY, NURSERY RHYMES, TOTEMISM, WITCHCRAFT, and on the more important writers. Some of the more important books have been already mentioned; among general books may be named Bastian, *Der Mensch in der Geschichte* (1860); W. K. Kelly, *Curiosities of Indo-European Tradition and Folklore* (1863), antiquated, but still suggestive; Liebrecht, *Zur Volkskunde* (1879); Lang, *Custom and Myth* (1884), his preface to Mrs Hunt's trans. of Grimm (1884) and to his edition of Perrault (1888); W. A. Folkmoot ('folk-meeting'; O.E. *mót, gemót*, 'assembly') was the old name in England for the public assembly of the nation for political and judicial purposes, or for collective deliberation. The old Germans had similar assemblies, as also the Scandinavians (the latter being called *Ting, Althing*). There were numerous local moots, such as the *shiremoot*, or county court. It cannot be said that there was in the old days a national folkmoot for all England, to which every freeman had a right to come; even the *Witenagemót* (q.v.) was not fully representative, but was rather a royal council of magnates. The *Moot-hall* was the hall of meeting; the *moot-hill*, the eminence or mound on which the open-air assemblies used to be held. The *mote* or *motte* (Old French), again, was the early Norman wooden castle on its mote-hill or artificial mound raised for the purpose—sometimes, no doubt, a moot-hill or older sepulchral mound utilised in this way (see CASTLE). See VILLAGE COMMUNITIES; Gomme, *Primitive Folkmoors* (1880).

Folksong, in music, has been defined as 'song and melody born of the people, and used by the people as an expression of their emotions and (as in the case of historical ballads) for lyrical narration.' It is passed on by tradition, often much changed in the course of transmission, till it is noted down by a collector. The folksongs of various peoples have sometimes exercised an invigorating influence on the works of composers; and, on the other hand, folksong is itself liable to be affected by the music of the conscious artist.

Folk melodies are very often constructed in one of the so-called ecclesiastical modes—Dorian, Mixolydian, Æolian, sometimes Phrygian; others again, including many Scots tunes, in the pentatonic scale. The Rev. John Broadwood in 1843 published a collection of *Old English Songs as now sung by the Peasantry of the Weald of Surrey and Sussex*. He was followed by Thomas Chappell, John Stokoe, Collingwood Bruce, Sabine Baring-Gould, Frank Kidston, W. A. Barrett, and Cecil Sharp. The Folksong Society was founded in 1898.

See Carl Engel, *Study of National Music* (1866); Kidston and Neale, *English Folksong and Dance* (1915); Cecil Sharp, *English Folksong* (1907); and the *Journal of the Folksong Society*. For the folksong as literature, see FOLKLORE, BALLAD.

Follicle. See HAIR, SKIN.

Fonblanque, ALBANY WILLIAM, English journalist, was born in London in 1793, and when only nineteen exchanged the law for journalism. As editor of the *Examiner*, a leading Liberal weekly journal, he exhibited a singular keenness both of wit and intellect, and exercised no inconsiderable influence on public opinion between the years 1830 and 1836. The characteristics of his political writings may be gathered from his *England under Seven Administrations* (1837), a reprint of articles published in the *Examiner* from the period of the Canning and Goderich ministries to the return of the Melbourne ministry. Fonblanque's services to the Whigs were rewarded by his appointment to the ungenial office of secretary to the Statistical Department of the Board of Trade in 1847. He died on 14th October 1872. A further collection of his writings from 1837 to 1860 was published by his nephew, together with a biographical memoir, in 1874.

Fond du Lac (Fr., 'end of the lake'), the capital of a county of the same name in Wisconsin, stands at the southern end of Lake Winnebago, 63 miles NNW. of Milwaukee by rail. It is connected by steamers with Lake Michigan, through Winnebago and the Fox River, and carries on a large trade in lumber. It has many manufactures. The city is supplied with water by nearly a thousand artesian wells. Population, 20,000.

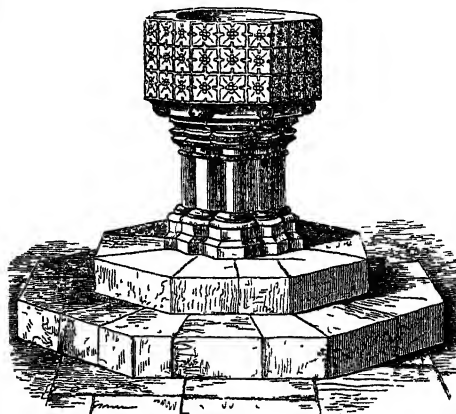

Fondi, a town of Italy, situated in the province of Caserta, NW. of Gaeta, and 6 miles from the sea, in a fertile but unhealthy plain, where grew the Cæcuban wine of classic times. The town, through which passed the Appian Way, is still partly surrounded by its ancient walls, and contains an old castle and a cathedral. Pop. 10,000.

Fonseca, a bay on the Pacific coast of Central America, discovered in 1522 by Gil Gonzalez de Avila.

Fonseca, ELEONORA PIMENTEL, MARQUESA DI, was born in Naples in 1758, and was lady-in-waiting to Queen Maria Carolina until she forfeited her mistress's favour by remarking on her intimacy with Acton (q.v.). In 1798 she was an active partisan of the French; but on the fall of the Parthenopean republic in 1799 she was sent to the gallows at the instigation of the queen.

Font (*fons baptismalis*), the vessel used in churches as the repository of the baptismal water. In the early period, while immersion continued to be the ordinary rite in the administration of the sacrament of baptism, the Baptistry (q.v.) was furnished with a basin in the floor sufficiently capacious to admit of the immersion of a certain number of converts at one time. When infant baptism became general, fonts of an oblong form were employed, of suitable size for the immersion of a child. When it became customary to baptise by affusion—i.e. by pouring the water on the head of the person to be baptised—the size of the basin was naturally diminished, and eventually it assumed the dimensions and the form which are now familiar to us in most of the medieval churches in Great Britain and upon the Continent. The baptismal font, in its normal form, consists of a basin or cup, more or less capacious, but usually about 2 feet 6 inches in diameter, hollowed out of a solid block, and supported upon a stem or pedestal. It is ordinarily of stone, but some ancient examples of leaden fonts also occur, and a few of copper or of bronze. In general it may be said that the font, in its external design and character, followed the prevailing style of ecclesiastical architecture and ornamentation. There is some doubt as to whether any existing specimen in England really belongs to the Saxon period; but

examples are found of all the later styles, from the Early Norman down to the latest revival of Gothic architecture in our own day; the Early English; the Decorated, of which a beautiful example exists in the church of All Saints, Norwich; and the Perpendicular, which is seen in its highest perfection at East Dereham in the same county of Norfolk. The annexed illustration exhibits a highly characteristic specimen of the fonts of the beginning of the 14th century, which stands in the church of Swaton, Lincolnshire, erected about 1310.

Font.

The external figure of the basin was often octagonal, sometimes circular, sometimes square, more rarely hexagonal. Ancient sarcophagi were sometimes employed. The basin was commonly supported on a single pillar or stem. Many cases, however, occur in which it rests on three, four, or five pillars, or, as in the engraving, on a group of pillars or pilasters united into a solid stem. In the square font the central basin rested on a solid central stem, and four shafts supported the four corners. The angles of the frame were used for carrying the salt, the oil, and the candles employed (see V. le Duc, *Dictionnaire*, vol. v. p. 539, for illustration). The exterior, as well of the basin as of the pedestal, was often highly decorated, ordinarily with sculpture, but occasionally also in gold and colours; the designs on the basin commonly representing subjects connected with baptism, or its types and symbols. We frequently meet around the pedestal figures of the apostles, sometimes only eleven in number, Judas being omitted.

In the Catholic Church the 'chrism,' or consecrated oil blessed by the bishop, and also the so-called 'oil of catechumens' are mingled with the baptismal water, which is reserved for subsequent use. With a view to the preservation of the water thus reserved, the font, especially when it is of porous stone, is sometimes lined with lead; and from an early date it has been furnished with a lid, which is secured by a lock. The lid was originally a flat wooden cover, but in later times it is carried up like a spiral canopy, and is often of a highly ornamental character.

The ordinary place of the font is at the western end of the nave, near the entrance of the church; but in some cases, especially on the Continent, it stands in a separate chapel or baptistery, or at least in a compartment screened off for the purpose. Even when it stands in the open nave, it is properly enclosed by a rail.

Fontainebleau, a town in France, in the department of Seine-et-Marne, is beautifully situ-

ated in the midst of a forest, near the left bank of the Seine, 37 miles SE. of Paris, with which it is connected both by steamers on the Seine and by railway. It furnishes a great deal of wine and fruit for the capital, and has manufactures of porcelain, and a sandstone quarry. Pop. 16,000.

Fontainebleau is chiefly famous for its château, or pleasure-palace of the kings of France, and the forest that surrounds it. The forest covers an extent of 65 sq. miles, and presents much fine scenery. The château is said to have been originally founded by Robert the Good toward the end of the 10th century. It was rebuilt in 1169 by Louis VII., of whom and of Philip Augustus it was a favourite residence, and was enlarged by Louis XI. and his successors. After being allowed to fall into decay, it was repaired and embellished by Francis I., by Henry IV., and by Napoleon I. Almost every king has added something in the way of enlargement or embellishment, so that it bears the character and style of almost every century. Louis-Philippe had all the paintings renovated, and the apartments restored in the taste of the 16th century. It was the residence of Christina of Sweden after her abdication, and here in 1657 she caused her secretary Monaldeschi to be executed. Under Louis XIV. it was occupied by Madame de Montespan, and under Louis XV. by Madame du Barry. Here Charles V. was entertained in 1539; here the decree for the revocation of the Edict of Nantes was signed in 1685; and here in the following year Condé died. In the château, too, Pope Pius VII. was detained a prisoner for nearly two years by Napoleon, and here this emperor signed the act of his abdication in 1814. In the forest Millet and other artists have lived and found their subjects.

Fontaines, MADAME DE, a French novelist, the date of whose birth is unknown. Her maiden name was Marie Louise Charlotte de Givri. She was a friend of Voltaire's in his youth, and died in 1730. She wrote *Aménophis* (a short story), and *La Comtesse de Savoie*, a tale of the 11th century.

Fontana, DOMENICO, an eminent engineer and architect, born in 1543 at Milì, on the Lake of Como. He became the papal architect in Rome, and was employed on many important public works, including the Lateran Palace and the Vatican Library. After the death of Sixtus V. he was royal architect and engineer in Naples, where he died in 1607.

Fontane, THEODOR (1819-98), German poet, essayist, and novelist, born at Neuruppin, had been a chemist until, in 1849, he took to literature in Berlin. See his *Autobiography* (2d ed. 1898), his *Briefe* (2d ed. 1905-10), and a *Study* by Hayens (1920).

Fontanes, LOUIS, MARQUIS DE, was born 6th March 1757, at Niort, in Poitou. After the completion of his studies he went in 1777 to Paris, where he acquired a reputation by his poems, *Le Cri de mon Cœur* (1778), *Le Verger* (1788), *L'Essai sur l'Astronomie* (1789), and *L'Épître sur l'Édit en Faveur des Non-Catholiques* (1789). He also wrote a metrical translation of Pope's *Essay on Man* (1783), with an elegant introduction, and an imitation of Gray's *Elegy*. In 1802 he was made a member, and in 1804 president, of the legislative body. His admiration of Napoleon was great; and his oratorical talents were often employed in eulogising the emperor's acts. In 1810 he entered the senate, and, passing on the fall of Napoleon into the service of the Bourbons, was raised to the peerage by Louis XVIII. He died at Paris, 17th March 1821. His writings, prose and poetic, which are regarded as models of elegance and correctness, were edited by Sainte-Beuve in 2 vols. in 1837, with a critical and biographical memoir.

Fontarabía, or FUENTERRABÍA, a picturesque old frontier town of Spain, at the mouth of the

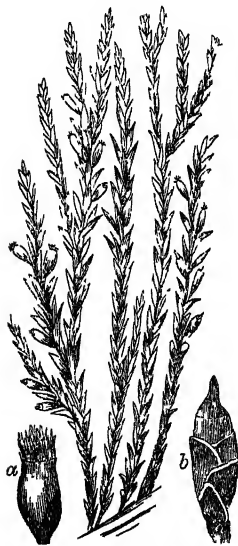

river Bidassoa, opposite to the French town of Hendaye, below the west extremity of the Pyrenees. It was long an important fortress, and the frequent object of contention between French and Spaniards, especially in 1638, when Condé was defeated, and in 1794, when its fortifications were demolished by the French. Battles were fought near by between Wellington and Soult in 1813, and during the Carlist war in 1837. Pop. 5600.

Fontenay-le-Comte, or FONTENAY-VENDEE, a town of France, in the department of Vendée, is situated at the head of navigation on the river Vendée, 27 miles NE. of La Rochelle. Its most remarkable buildings are the beautiful Romanesque church of Notre Dame, with a Gothic spire 311 feet high, and the fountain from which the town is said to have derived its name. Pop. 9000.

Fontenelle, BERNARD LE BOVIER DE, was born at Rouen, France, 11, 1657. His mother was a sister of Corneille. He was educated by the Jesuits and studied for the bar, but entered early in life upon a purely literary career in Paris. In the great quarrel of Moderns *versus* Ancients, which was then raging in France, he took part with La Motte and the other champions of the Moderns, assailing the Greek writers and their French imitators, and receiving in return the satiric shafts of Boileau, Racine, J. B. Rousseau, and La Bruyère. La Bruyère ridiculed him pitilessly in the *Caractères*, where he figures as Cydias, the pedant who ranks himself above Plato and Theocritus, and confidently awaits the hour when men will recognise his superiority to Homer. After the failure on the stage of his *Aspar*—a play to which Racine ascribed the origin of the practice of hissing in theatres—Fontenelle produced an imitation of Lucian, entitled *Dialogues des Morts*, and the *Lettres du Chevalier d'Her...*, a work of fiction written in the 'precious' style afterwards adopted by Marivaux. Thenceforth he devoted himself mainly to literary criticism and to the task of popularising science. His prose works brought him a remarkable reputation, which was to some extent merited by the elegance of the style and the perspicuity of the exposition. In 1697 he was made secretary to the Académie des Sciences, of which he afterwards became president. His *Éloges des Académiciens* added greatly to his fame, and after the death of Boileau in 1711 he enjoyed a well-nigh absolute rule in the Academy. He died in his hundredth year at Paris, on January 9, 1757; and is thus a link between the age of Molière and Boileau and the age of Diderot and Voltaire. He was a man of remarkable vigour and versatility of intellect. The best writers of his day endeavoured in vain to crush him. Had he not possessed rare strength of character he must have succumbed to the attacks of the brilliant men whose enmity he incurred. He attempted well-nigh every form of literature, he wrote idylls, and satires, and dialogues, and critical essays, histories, and verses of society, tragedies (*Aspar* and *Idalie*), scientific treatises, and operas (*Endymion*, *Thétis et Pélée*, &c.). He has left no book of outstanding merit; he was not a strong original thinker, and he seems to have cared less for truth than for paradoxes and piquant phrases. But his learning was far from contemptible, his style was graceful, and his wit was keen. His best works, the *Entretiens sur la Pluralité des Mondes*, and the *Histoire des Oracles*, the latter based on the treatise of the Dutchman, Van Dale, are still worth reading for the felicity of the expression and the frequent acuteness and ingenuity of the thought. Andrew Lang discovered the germ of his explanation of myths in Fontenelle's dissertation on Fables.

Fontenoy, a village of Belgium, 5 miles SE. of Tournay, was the scene of a battle (11th May 1745) in the war of the Austrian Succession, between the French, 60,000 strong, under Marshal Saxe, and the allies (English, Dutch, and Austrians), in nearly equal force, under the Duke of Cumberland. After a hard-fought fight the allies were forced to retreat, the loss on each side being about 7000 men. The victory was in great measure due to the courage of the 'Irish Brigade' in the French army, much besung by Irish poets. See F. H. Skrine's *Fontenoy* (1906).

Fontevrault (*Fons Ebraaldi*), a town in Maine-et-Loire, 8 miles SE. of Saumur (pop. 2000), which owes its origin to a celebrated abbey founded by Robert d'Arbrissel, a Breton monk, in 1099, as the residence of a monastic society composed of both nuns and monks. The society followed the rule of Benedict, but was governed by an abess, not by an abbot. The order of Fontevrault, which received the papal sanction in 1106 and 1113, soon spread through France and into Spain, and acquired great riches. The abbesses belonged for the most part to illustrious families, and were subject only to the pope. At the outbreak of the French Revolution there were fifty-seven priories of the order in France, which, however, were then abolished. The 12th-century church contains sepulchral monuments to several English sovereigns and princes, including Henry II., his queen, Eleanor of Guienne, Richard Cœur-de-Lion, and Isabella, the queen of John. Since 1804 the old monastic buildings and courtyards have been used as one of the central prisons of France, accommodating about 2000 convicts. See *Fontevrault et ses Monuments*, by Edouard (2 vols. Marseilles, 1874).

Greater Water-Moss (*Fontinalis antipyretica*):

a, spore-case or capsule, divested of calyptra and lid, showing the peristome; *b*, spore-case, with its involucre of leaf-like scales.

stalk. Several species are British; one of which, the Greater Water-moss (*F. antipyretica*), growing upon rocks and roots of trees in brooks and ponds, is remarkable for the difficulty with which it burns, even when completely dried; on which account it is used in some parts of the north of Europe for lining chimneys to protect the adjacent woodwork from fire. Its shoots are a foot or more in length, and branched; they float in the water. The fruit is on the sides of the stems.

Foochow (*Fu-Chau*), capital of the Chinese province of Fu-chien, with suburbs extending to the river Min, 25 miles above its mouth. The town proper is surrounded with walls nearly 30 feet high, and 10 feet wide at the top. The river is thronged with floating houses, and is crossed by a great bridge, 329 yards long, built of huge slabs of stone, some of them 42 feet in length, resting on forty piers. The Min provides an easy communication with the interior, with which a large trade

is carried on in timber, paper, and cotton and woollen goods; and the port, opened to foreign commerce in 1842, is one of the principal tea-markets and mission stations in China. The trade has declined owing to the competition of Indian teas; but the annual export is still extensive. There is also trade in salt, iron, fruits, and fish. The imports are chiefly cotton goods, sugar, rice, and beans. There are manufactories of silk and cotton fabrics and paper, and some shipyards; and on an island some three miles down the stream there is a large government arsenal. Pop. about 320,000.

Food is generally taken to indicate those solid matters which are consumed for the nourishment of the body, yet it is convenient to use the term with a much wider significance. Under the term food we are forced to speak of all matters ingested for nutritive purposes, irrespective of their physical conditions, and to include beverages of various kinds, and even the air we breathe. There is the following very simple reason for this somewhat extended definition of the word. Water is the basis of all beverages, and no ordinary solid food is without some water, while on the other hand most beverages, wine, beer, tea, &c., contain solid matter dissolved in water. Air, as every one knows, is a vital and ever-pressing necessity, and its action within the body is eminently nutritive. The tissues of the body consume its oxygen as well as the nutritive parts of beef and mutton; and air we must therefore include within our extended definition.

The classification of food into solid food, beverages, and air would, however, be an unsatisfactory one. The chemist has been able to divide the food-stuffs, as we may call them, into classes, by sorting into groups substances which have similar chemical and physical properties. This arrangement has the advantage that members of the same class have nearly always similar properties as regards their nutritive functions.

THE VARIOUS KINDS OF FOOD-STUFFS.

NITROGENOUS ..	{ Proteins.
	{ Nitrogenous extractives
NON-NITROGENOUS	{ Carbohydrates
	{ Fats
	{ Vegetable acids.
	{ Inorganic salts.
	{ Water.
	{ Air (oxygen).

The Nitrogenous Foods.—These all contain nitrogen, and, inasmuch as during life nitrogen is invariably, and under all circumstances, excreted by the body, it must be replenished by nitrogenous food-stuffs. The proteins (albuminoid substances) are found both in the animal and vegetable world. Among animal proteins are the white of egg, the vitellin of the yolk, myosin from muscle (flesh of meat), fibrin and albumen from blood, and gelatin from bones. In the vegetable world vegetable albumens and globulins are present, and in the grains and seeds of plants they are found in quantity. Nitrogenous extractives are found in the muscles (flesh) of animals, and are probably of great value, chiefly as stimulants. Beef-tea is an extract of these from the muscle of the ox, and they are found in rich animal soups.

The Carbohydrates.—These are food-stuffs containing carbon, oxygen, and hydrogen, but no nitrogen. Moreover, the oxygen and hydrogen are present in the proportions which form water. The vegetable world furnishes us with the most important carbohydrates. These are the various starches and dextrines. Then we have the sugars—cane-sugar, grape-sugar, sugar of milk or lactose, &c. The flesh and other eatable parts of animals are poor in carbohydrates; nevertheless the latter are

found there. Glycogen (q.v.) or animal starch is widely distributed, although, except in the Liver (q.v.), it is present in small quantity.

Fats and Oils.—These substances, of a very high nutritive value, are found in both the animal and vegetable world. In vegetables they are especially abundant in seeds and fruits. In the animal world we find them in the tissues under the skin, and in many animals, such as whales, seals, &c., the blubber, as it is called, is present in enormous amount. The liver is generally found to contain a great deal of fat, as is also the tissue round the kidneys, and round other abdominal organs. The chief fatty matters present are olein, stearin, and palmitin.

Vegetable Acids.—The action of these substances as food-stuffs, though important, is not altogether understood; but their withdrawal from the food may lead to serious inconvenience. The most important vegetable acids are tartaric, oxalic, citric, acetic, and malic.

Inorganic Salts.—Of these the most important is common salt, or sodium chloride. It is present in small quantities in all foods, but in addition man requires as a rule a larger quantity. It greatly assists digestion, and probably is necessary for the formation of the gastric juice. Whereas it can pass through the system if taken in large quantities, yet a certain amount is required by the body to establish within it those conditions under which alone life is possible. Thus, many of the proteins would suffer complete alteration were it possible to abstract all the salt from the body, and the blood would become at once a turbid fluid which would rapidly cease to flow. In addition to sodium chloride there are many other salts required, such as potassium chloride and the phosphates of calcium and magnesium, the latter for the formation of bone. Iron salts are required for the formation of the colouring matter of the Blood (q.v.).

Water.—This all-important substance is taken in its natural form as spring, river, well, or rain water. In all cases certain inorganic salts are held in solution, which vary in their nature and quantity with the soil with which the water has come in contact. Organic (both animal and vegetable) matter may be present, especially in river and shallow well water. In addition, water is present in almost every kind of solid food, as well as in liquid foods and beverages. Bread, meat, cheese, potatoes, all contain a large quantity of water, and such substances as flour and biscuits are rarely free from a trace of it. Its importance for the needs of the economy are at once apparent when we recollect the large amount daily excreted by the lungs, the kidneys, and the skin, all of which require replenishing.

Air.—From the atmosphere we breathe oxygen is obtained, without which the other classes of food-stuffs would avail us little. Their destination is, in fact, to meet with this oxygen, and suffer changes called 'oxidation changes' within the tissues of the body.

SOURCES OF THE FOOD-STUFFS.—*The Carcasses of Animals.*—From the carcasses of animals we obtain meat and bones and fat, all of which have an important nutritive value. Cartilage, gristle, and yellow elastic tissue (pax-wax) are of almost no utility. Meat consists of from 70 to 80 per cent. of water, and the rest of proteins, extractives, fats, salts, and indigestible substances. The proteins of meat form about 20 per cent. of the whole; they are easily digestible, more so perhaps than are the vegetable proteins. Amongst the protein fibres of the meat a certain amount of fat is generally lodged, and here and there it is collected in larger masses. The percentage quantity varies immensely, but even in lean meat there is on an

average 2 per cent. of fat present. The extractives of meat are valuable stimulants of digestion, and the salts, chiefly chlorides and phosphates, are very abundant. The flesh of domesticated mammals, such as oxen, sheep, and pigs, is especially rich in fat. The same may be said of fowls, ducks, and geese. The flesh of wild mammals and birds contains less fat, and very little is ever present in the flesh of fish. The flesh of animals is almost invariably eaten after cooking. In this case the proteins are coagulated, the fibrous tissue of the meat is softened and rendered more digestible, and the savoury qualities of the meat are developed.

Meat may be cooked directly after killing, and in this case it is tender and very palatable. If the animal be kept for even a few hours the meat becomes hard owing to death coagulation; cooked at this stage it is tough and indigestible; it requires to be kept until it softens again. If kept for some time meat putrefies and becomes high. Game is generally eaten in this condition, and it is readily digested, and admirable in flavour. It is, however, apt to disagree with many people, and even fatal consequences may follow its consumption. High meat is putrid meat; the proteins have in part decomposed, but the remainder is partly in the very digestible form of a peptone protein. The meat contains microscopic organisms termed Bacteria (q.v.), and is full of their excretions (see PTOMAINES). Mussels, oysters, and other shell-fish sometimes produce bad dyspepsia, nettle-rash, and even graver symptoms, although they are eaten perfectly fresh. Many fish, especially during the breeding season, are quite unpalatable or even poisonous, apart from putrefactive changes. These fish are for the most part inhabitants of the tropical seas. Idiosyncrasy plays a very important part in our selection of animal foods. Diseased meat is always to be avoided. No one questions the fact that the flesh of the pig affected with *Trichina spiralis* must be avoided. The parasites are not at all readily killed by cooking, and very dangerous febrile symptoms are produced by the action of the young trichinæ which wander into the tissues. Tapeworm is also produced by the consumption of the flesh of the pig and ox, although if the flesh be thoroughly cooked the danger is greatly diminished.

Bones of animals are very important articles of food. In the interior of the shafts one finds the yellow marrow, consisting of fat of a very savoury taste. At the ends of the bones is situated the red marrow, which is practically devoid of fat, but is rich in nitrogenous extractives. The whole bone, too, is porous, and boiling is able to extract from its interior a rich supply of nitrogenous extractives. Hence bones are useful for making soups, which we may look upon as hot decoctions of salts and extractives, having a useful stimulating action, but not of any great nutritive value, unless thickened by the addition of pieces of meat or vegetables, which should be served up with the soup. The bone itself consists of a gelatin-yielding substance termed *collagen*, which is chemically united with earthy inorganic salts. This gelatin may be removed by prolonged boiling, and is used for making jellies, and for various other purposes.

Cereal Grains.—These are very important articles of food, and are largely used by mankind in nearly all parts of the globe. The most important cereal grains are those of wheat, oats, rye, barley, rice, and maize. They form very condensed articles of food, containing little water, and consisting of highly nutritive solid matter. They all contain an abundance of starch, together with smaller quantities of dextrine and sugar. Protein matters are also present in no inconsiderable amount, consisting chiefly of insoluble substances, such as gluten-casein, gluten-fibrin, gliadin, together with

some soluble albumen. The cereals are as a rule deficient in fat and salts.

Wheat-flour and Bread.—Wheat is rich in albuminous matter, containing about 12 per cent. It contains about 70 per cent. of starch, and very little fat. The grain is crushed and separated into flour and bran. With the loss of the bran the flour loses some fat, salts, and nitrogenous matter; on the other hand, bran is irritating to the digestive mucous membrane. Whole-meal bread is therefore more nourishing, but is apt to disagree.

If flour be mixed with water it forms a sticky dough or paste. This consists of gluten, a nitrogenous substance of a sticky nature, by which the granules of starch are held together. On heating this dough, with or without admixture of eggs, milk, &c., pastry, biscuits, &c., are made. Macaroni is made by forcing dough through small apertures during the application of heat. Bread (q.v.) is dough inflated with carbon dioxide, which gas may be generated in the dough itself, or may be driven into it by pressure. When flour is converted into bread much of the starch is converted into the more easily digested dextrine, and the albumens are coagulated and otherwise changed. It is rendered soft and open, readily permeable by the digestive juices. One hundred pounds of flour yield about 135 lb. of bread. See BISCUITS.

Oats and Oatmeal.—Oats have this advantage over wheat, that they contain more fat and more saline matter. They may be looked upon on this account as more valuable food, when the diet is limited to a few articles only. They are ground into oatmeal, from which porridge may be made. Oatmeal boiled with a large quantity of water, so as to form a drink, has been highly spoken of. It is capable of forming a much more sustaining drink than perhaps any other, and is much advocated for the use of labourers, especially for those engaged in harvesting or in other labour where great exertion has to be made in a short space of time.

Barley, Maize, and Rye.—These are very nutritious, the maize containing about 6 per cent. of fat, in addition to albuminous and starchy matter. Rye and barley are apt to produce intestinal irritation.

Rice.—This grain is poor in nitrogen, and contains little fatty matter; so that those who subsist almost entirely upon it are obliged to supplement its deficiencies by admixture with fat, and with protein matter either in the form of milk or legumes. It should not be cooked by any boiling process, inasmuch as during the process it loses much of its nutritive value, the albumens being in part dissolved away. It should be steamed in preference.

The Legumes or Pulses.—These include the peas, beans, and lentils. They are distinguished by containing large quantities of nitrogenous matter, and accordingly their chief utility is to supplement the deficiencies of starchy and fatty food. They are eaten with rice in India, and in England they form a favourite dish—'beans and bacon'—equivalent to the 'baked beans' of New England. The Mexicans, however, are the greatest consumers of beans (*fríjoles*) in the world, although this vegetable is nearly equally popular throughout Central America; and the *garbanzo*, or chick-pea, fills the place of the potato in Spain. Lentil soup is a valuable food. The pulses are not readily boiled, and are not digested very easily.

Vegetable Roots, &c.—Vegetable roots and tubers yield abundant food to man, of a highly nutritive quality, and containing as a rule a large quantity of starchy matter. The potato is one of the most important tubers. As it contains little nitrogenous and fatty matters, these must be added when the diet consists largely of potatoes. This tuber should be steamed rather than boiled: it is very

digestible, especially when not too young. Since 1845, the year of the great potato disease, the plant has deteriorated, and, some maintain, is a less nutritive food than it had previously been. Arrow-root, which consists almost entirely of starch, and is largely adulterated with other forms of starch, cannot be considered in any other light than that of a single food-stuff, and in consequence it must always be used as an addition to other foods. The same remark applies to Tapioca (q.v.), and to sago, although this latter is obtained not from a root, but is cut away from the centre of the stems of several kinds of palm-trees. Other roots are the Jerusalem artichoke, containing sugar and nitrogenous matter, and turnips, carrots, and parsnips, containing starch, sugar, and a small quantity of nitrogenous matter. Beet-roots, mangold-wurzels, and radishes are all succulent roots, containing both starch and sugar.

Vegetables.—The most important vegetables are members of the cabbage tribe, amongst which may be mentioned the common cabbage, the red cabbage, cauliflower, Brussels sprouts, various kales, and broccolis. These have not a very high nutritive value, but they supply the economy with useful salts, and are in consequence very highly antiscorbutic. Much the same may be said for the lettuce, onion, mustard, cress, endive, &c.

Fruits.—These are of value chiefly on account of the sugar and vegetable acids they contain. The sugar is in a form which is readily absorbed; and, on account of the large quantity of vegetable acids, they have a very important antiscorbutic action.

Nuts, such as coconuts, walnuts, Brazil-nuts, are rich in oily and nitrogenous matter. They are not easily digested, however.

Beverages.—Water is the main constituent of every beverage. Most beverages contain solid matter, either in solution or in a state of suspension. We may divide beverages into nutritive and stimulating, the most useful ones combining both these properties. Perhaps the most important nutritive beverage is milk. It contains all the necessary food-stuffs, as is shown by the fact that the newly-born child can thrive on it alone. Its percentage composition is nitrogenous matter, 4 per cent.; fat, 4; milk-sugar, 5.2; salts, 8; water, 86 per cent. The composition varies in different breeds of cows. The Alderney cow yields a milk that is very rich in fat, while the milk of the long-horned cow is rich in casein. It varies too with the pasture, and may even acquire poisonous properties. The peculiar taste of the milk from cows fed on turnips is well known to every one. The milk of the ass may frequently be taken by persons who are unable to digest cow's milk. Cream consists of the fat of milk, and is obtained by allowing freshly drawn milk to stand for some hours. The lighter cream floats to the surface, and may be removed. The name 'skimmed milk' is applied to the residue after removal of the cream. Butter-milk contains less fat than does skimmed milk. It is, however, of important nutritive value, as it contains much nitrogenous matter, salts, and sugar.

Tea, Coffee, and Cocoa are restorative beverages having a stimulating action. They have little nutritive value unless taken with milk and sugar. Tea contains an astringent substance—tannin, which causes the rough taste experienced when it is drunk without milk. The addition of a few drops of the latter substance prevents its astringency, by precipitating the tannin as an insoluble albuminous tannate. It should be made by pouring boiling water over the leaves; if the leaves are boiled in water they lose their aroma, and much astringency is developed. On account of its astringency tea

slightly impedes digestion and lessens the action of the bowels. Theine is the active principle. Coffee has, roughly speaking, the same composition as tea. Its active principle is *caffeine*, and it contains a tannic compound and a characteristic volatile oil. As a beverage it is stimulating; but it retards digestion and the action of the bowels. Like tea, it is said to prevent tissue waste, and it increases the action of the skin. Cocoa is much more nutritive than either tea or coffee, as it contains starch and a large quantity of fat and protein matter. Chocolate is prepared by adding sugar and flavouring matter to the cocoa. See also KOLA.

Alcoholic Beverages.—Alcohol is an article of food of some nutritive value, though perfect health is compatible with total abstinence (see ALCOHOL). Alcohol is undoubtedly oxidised within the body, although if taken in any quantity the excess is eliminated. Taken in reasonable quantity it stimulates the action of the heart, and probably raises slightly the temperature of the body; but it retards to some slight extent the action of the gastric juice. It is also a mental stimulant, producing exhilaration. In many alcoholic beverages a large quantity of saccharine matter is present, and these may in consequence hold a place as possessing high nutritive qualities. Such are beer and porter. Bitter principles, when present, as in beer, are gastric stimulants, and probably assist digestion by increasing the secretion of the gastric juice.

The Economics of Food.—In temperate climates when a pastoral people turn their attention to agriculture they become to a great extent vegetable feeders. Their diet no longer consists chiefly of the flesh and milk of animals, but in addition includes the use of a large proportion of grains, pulses, and other vegetable food-stuffs. The agricultural race in time displaces the pastoral one, for several reasons. In the first place, the very fact that the art of agriculture has been acquired commonly indicates a greater mental development, certain to exercise its full weight in the struggle for existence. In addition, however, there is another and an equally potent reason. Vegetable matter is, and must always be, more economical as a food-stuff than animal matter. A given area of soil must always yield food-stuffs of a more nutritive value if that soil has been used to cultivate vegetables such as corn, oats, &c., to be eaten directly by man, than if it be used for the maintenance of any animal kept for the subsequent nutrition of man. The reason is very simple. A vegetable has a certain nutritive value—i.e. it will yield when eaten so much muscular energy, &c. If eaten by man it will directly administer to the energy of his body, and his muscles and brain will be nourished by it. If it be given to an ox part will no doubt go to the nourishment of the ox, and then, if the ox be eaten, to the nourishment of the man. The greater part, however, will be consumed by the ox to obtain materials for *its own energy*. Every step it takes, the perpetual movement of its jaws in chewing, the whisking of its tail to chase away a fly, these are all deductions to be made out of the nutritive value of its food, and the residuum alone, and that a comparatively small one, is what is obtained when the ox is consumed. So truly is this understood by practical men that they try to lessen these deductions to the greatest possible extent. They prevent as much movement as possible on the part of the animals to be used as food, penning up the poultry, and placing the pig, naturally an active and intelligent animal, within the confines of a sty. In order that the animal may be compelled by a process of exclusion to devote itself entirely to feeding and to furthering the development of fat, it is rendered **asexual** by an operation which is in a high degree

painful. Nevertheless, these deductions are only lessened in some degree, and it will ever be impossible to get rid of them altogether. It follows, therefore, from what we have said that, at any rate in a thickly populated country, it is an economy to go straight to the vegetable world for food rather than to consume the flesh of animals. The high price of meat is an indication of what has just been alluded to. There is a loss in converting vegetable into animal produce, and the value of the latter rises in proportion to that loss. Life may be very cheaply sustained on vegetable produce, such as bread, oatmeal, peasemeal, &c. The cost of animal food is two or three times as great in the case of milk, cheese, and butter, and about twelve times as much in the case of beef, veal, ham, &c. According to Frankland, if an average man were to confine himself to one article of diet he would require, to support life from day to day, 5·068 lb. of potatoes; 1·156 lb. of Cheshire cheese; 1·335 lb. of peasemeal; 1·341 lb. of ground rice; 2·345 lb. of bread; 3·532 lb. of lean beef; 4·300 lb. of lean veal; 6·369 lb. of whiting; 8·745 lb. of white of egg; 2·209 lb. of hard-boiled egg; 9·865 lb. of carrots; 12·020 lb. of cabbage; ·693 lb. of butter; ·555 lb. of beef fat; 6½ bottles of stout. It is not, of course, supposed that healthy existence can be maintained on one or two food-stuffs alone; the diet should be varied as well as plentiful, and in order to be economical it must be drawn largely from the vegetable world.

The various countries of the world differ very widely in regard to their power of producing within their own borders food and to spare for all their inhabitants. The United States is the most conspicuous example of a country which raises in superabundance the essential food-stuffs required by its own people, and has of many kinds a large surplus available for export. Few European countries save Russia are self-sufficing in this way. Great Britain is the most notable example of a country which is very largely dependent on foreign countries for the food of its people, and to an ever-increasing extent. The meat-supplies (including animals) come from the United States, Argentina, Denmark, New Zealand, and Canada; butter from Denmark, France, Russia, and Canada; sugar from Germany, France, and British West Indies; cheese from Canada, United States, and Holland; eggs from Russia, Denmark, and Germany.

However great be the advantage to Great Britain in having access thus freely to the best markets of the world, there is one aspect of the consequent dependence upon foreign countries which has caused misgivings. What could a country dependent for such a large proportion of its food-supplies on foreign countries do in time of a war with a great state, even if it were not one of those on which it was directly dependent? This problem was referred to a Royal Commission which was appointed in 1903 and reported in 1905. The Great War of 1914–18 led to a practical working out of part of the question, notwithstanding the failure of the submarine to stop importation. Within the country, government control of distribution was resorted to, while the food-hoarder and the profiteer sprang to notoriety.

By botanists the word food is commonly applied not to the substances taken into the plant-body, but to those which the plant itself elaborates from them. A green plant obtains water and dissolved salts from the soil, and carbon dioxide from the air. From these it forms carbohydrates, proteins, &c., on which it feeds. Parasites and saprophytes, of course, get their food ready-made.

See ADULTERATION, DIET, DIGESTION, COOKERY, INFANTS (FEEDING OF), PARASITIC ANIMALS, VEGETARIANISM, and the books there cited; also ALCOHOL,

BEER, BREAD, CHOCOLATE, COCOA, COFFEE, PRESERVED PROVISIONS, VITAMINS, WINE, &c For plants, see PHYSIOLOGY (VEGETABLE), CHLOROPHYLL, ROOT, SAPROPHYTIC PLANTS, PARASITIC PLANTS, FUNGI, BACTERIA, SYMBIOSIS, NITRIFICATION, NITROGEN-FIXATION, &c.

Fools, or JESTERS, persons who were kept in the households of princes and lesser dignitaries to furnish amusement by their real or affected folly. Wace has left a curious account of the preservation of William the Conqueror's life by his fool Goles. Other fools whose names have descended are the Hitarid of Edmund Ironside, the Will Somers of Henry VIII., Archie Armstrong, who lost his office for jests which the petty-minded Laud could not endure; and in France Caillat and Triboulet in the time of Francis I., and Chicot in the reign of Henry III. Triboulet figures in Rabelais, and is the hero of Hugo's *Le roi s'amuse* and of Verdi's *Rigoletto*. The last private person to keep a fool in England was Lord Suffolk, whose jester, Dicky Pierce, was buried at Berkeley in 1728. Jamie Fleeman (1713-78), the Laird of Udry's fool, is yet remembered in Buchan.

In the East the office of jester existed in the 8th century, and probably much earlier in India. The famous Khalif Haroun al-Raschid had a jester named Bahalul, some of whose sayings and doings have been preserved by Arabian writers. He appears to have possessed vivacity, wit, and observation, which were, however, often concealed under a mask of simplicity, and he was permitted to take great liberties with the khalif's courtiers. 'I wish,' said Haroun to him one day, 'I wish you would procure me a list of all the fools in Bagdad.' 'That would be difficult, O Commander of the Faithful,' replied the jester; 'but if you desire to know the wise men, the catalogue may soon be completed.' This found its way—*mutatis mutandis*—into English jest-books in the 16th century. One day Bahalul was discovered seated on the khalif's throne, for which Haroun awarded him a whipping; then said the jester, 'O Commander of the Faithful, I sat in this seat only half-an-hour and have been whipped for doing so; what do *you* deserve who sit in it every day?'

A collection of Ramakistnan's jests in the Tamil language was translated into English and Telugu by Narrain Sawmy, and published at Madras in 1839, and not a few of them are almost identical with tales ascribed to European court jesters, such as our English Scogin and the Italian Gonella. This almost unknown little book explains how he was endowed with so much wit that he became the greatest jester in the world, and by the exercise of this wit at the court of a raja, was able to maintain himself and family. Like the European court jesters, Ramakistnan's too ready wit frequently roused his royal master's wrath; but though sometimes condemned to death he always evaded it, and was again and again received with favour through his irresistible drollery. His jests, however, have none of the coarseness which is the chief characteristic of his western brethren; for example, in his counterpart to the well-known jest of Scogin, when the king commanded him never to show his face in the royal presence again, he saves propriety and carries out his jest by entering with a large pot over his head and down to his shoulders. The Shakespearian stage fool has been traced to the Vice of the mystery and morality plays. See Douce, *Illustrations of Shakespeare* (1807); Dr Doran, *History of Court Fools* (1858); Lionel Johnson in *Noctes Shakespearianæ* (1887); H. Bradley in *A Book of Homage to Shakespeare* (1916); O. M. Busby, *Studies in the Development of the Fool in Elizabethan Drama* (1923). For APRIL FOOLS, see APRIL.

Fools, FEAST OF. The Romans kept the festival of Saturn, in December, as a time of general license and revelry. During the brief season of the Saturnalia (q.v.) the slave reclined on his master's seat at table, the master waited upon his slave, and society for the moment seemed to be turned upside down. The grotesque masquerade survived the pagan creed which gave it birth, and not only kept its place among the Christians, but, in the face of solemn anathemas from fathers and councils, found its way into the ceremonial of the Christian church. It was called, at different times and places, by many different names, but latterly came to be best known as the Feast of Fools (*Festum Fatuorum*, *Festum Stultorum*). The rites practised varied greatly, but were everywhere marked by the same spirit of broad, boisterous drollery, and coarse but not ill-natured caricature. The donkey played such a frequent part in it that the pageant was often called the Feast of Asses (*Festum Asinorum*). In some places the ass of Balaam was figured; in others, the ass which stood beside the manger in which the infant Saviour was laid; elsewhere, the ass on which the Virgin and Child fled to Egypt, or the ass on which Jesus rode into Jerusalem. In every instance there was more or less attention at dramatic representation, the theatre being generally the chief church of the place, and the words and action of the drama being often ordered by its book of ceremonies. Several rituals of this sort are still preserved: that which was in use at Beauvais, in France, has a rubric ordering the priest when he dismisses the congregation to bray three times, and ordering the people to bray three times in answer. As the ass was led towards the altar he was greeted with a hymn. Where the ass did not come upon the stage the chief point of the farce lay in the election of a mock pope, patriarch, cardinal, archbishop, bishop, or abbot. These mimic dignitaries took such titles as 'Pope of Fools,' 'Archbishop of Dolts,' 'Cardinal of Numskull,' 'Boy Bishop' (q.v.), 'Patriarch of Sots,' 'Abbot of Unreason,' and the like. On the day of their election they often took possession of the churches, and even occasionally travestied the performance of the church's highest office, the mass, in the church's holiest place, the altar. In some convents the nuns disguised themselves in men's clothes, chanted mock services, and elected a 'little abbess,' who for that day took the place of the real abbess.

The Feast of Fools maintained itself in many places till the Reformation in the 16th century. At Antibes, in the south of France, it survived till the year 1644, when we have it described by an eye-witness in a letter to the philosopher Gassendi. The scene was, as usual, a church; and the actors, dressing themselves in priests' robes turned inside out, read prayers from books turned upside down, through spectacles of orange-peel, using coal or flour for incense, amid a babblement of confused cries, and the mimic bellowings of cattle, and grunting of pigs. See Tillot, *Mémoires pour servir à l'Histoire de la Fête des Fous* (Lausanne, 1741), and Schneegans in Müller's *Zeitschrift für Deutsche Kulturgeschichte* (1858).

Fool's Parsley (*Æthusa Cynapium*), an umbelliferous plant, common as a weed in gardens and fields in Britain, and in most parts of Europe, somewhat resembling parsley in its foliage and general appearance, so that serious accidents have occurred from its being mistaken for that herb; for it is a poisonous plant, somewhat resembling hemlock in its properties. With the curled variety of parsley it cannot easily be confounded; the leaves are smaller and glossy, and have a disagreeable garlic-like odour when rubbed. The growth is annual, but at first more rapid than that of true

parsley. When in flower it is readily known from every other plant in British gardens by its umbels wanting general involucre, but having upon the secondary umbels partial involucre of three slender leaves hanging down on one side.

Fool's Parsley
(*Æthusa Cynapium*):

supposed resemblance to the dice used by the Romans. Above, it articulates with the two bones of the leg, the *tibia* and *fibula*, and through these bones the whole weight of the body is thrown upon the two *astragali*. Below, it is connected with and rests upon the *os calcis*, or heel-bone, which is the largest bone of the foot. Immediately in front of the astragalus, and supporting it in this direction, is the *scaphoid* or boat-like bone.

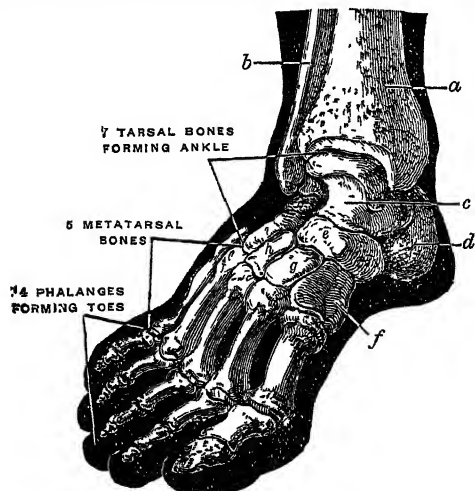

Fig. 1.—Bones of the Foot and Ankle:

a, tibia; b, fibula; c, astragalus; d, os calcis, or heel-bone; e, scaphoid bone; f, g, h, the internal, middle, and external cuneiform bones; i, cuboid bone.

In front of the scaphoid bone are the three *cuneiform* or wedge-shaped bones; and on the outer side of the cuneiform bones, and in front of the os calcis, is the *cuboid* bone. We see from fig. 1 that the front row of tarsal bones is composed of the three cuneiform bones on the inner side of the

foot, and of the cuboid bone externally. There are five metatarsal bones passing forward, one for each toe. Each cuneiform bone is connected with one, and the cuboid bone with two, of these metatarsal bones. Behind, they are close together, but as they run forward they diverge slightly from one another, and their anterior ends rest upon the ground and form the *balls* of the toes. They constitute the forepart of the instep. The remaining bones are those of the toes, and are named the *phalanges*, each toe having three of these bones, excepting the great toe, which has only two. (A similar law holds for the bones of the hand, each finger having three phalanges, but the thumb only two.)

The instep is composed of the seven tarsal and the five metatarsal bones, which are so arranged and connected (see fig. 2) as to form the *plantar arch* from the extremity of the heel-bone to the balls of the toes. The astragalus forms the summit or keystone of this arch, and transmits the weight which it receives back to the heel, and forward to the balls of the toes.

The bones where they articulate with one another are covered with a tolerably thick layer of smooth cartilage, and by this means, together with the very slight movements of which each bone is

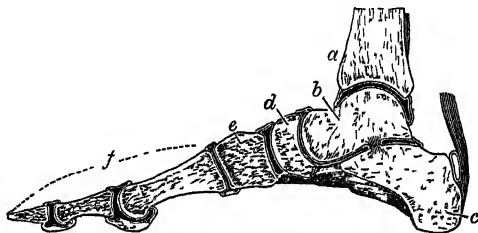

Fig. 2.

Section through the lower end of the tibia a, and through the astragalus b, the heel-bone c, the scaphoid bone d, the internal cuneiform bone e, and the bones of the great toe f.

capable, a degree of elasticity is given to the foot, and consequently to the step, which would be altogether wanting if the plantar arch were composed of one single mass of bone. This elasticity is far greater in the anterior pillar of the arch, which is composed of five comparatively long bones sloping gradually to the ground, than in the posterior pillar, which is short, narrow, and composed of a single bone, which descends almost vertically from the ankle to the ground. Hence, in jumping from a height, we always endeavour to alight upon the balls of the toes, and thus break the shock which we should feel if by accident we descended upon the heels.

The bones of the foot are held together by short ligamentous bands of great strength. These are attached to the non-articular surfaces of the bones, and are arranged mostly on their *plantar* and *dorsal*—i.e. upper—surfaces, while others are situated between bones, and are hence named *interosseous*. So resistant are these ligaments that it is almost impossible to dislocate the bones which they hold together.

The spot over which the inferior calcaneo-scaphoid ligament extends is the weakest in the foot, the astragalus being there unsupported by any bones; additional support is, however, afforded where it is more required by the tendon of a strong muscle, the *posterior tibial* (fig. 3, B), which passes from the back of the tibia (the chief bone of the leg) round the inner ankle, to be inserted into the lower part of the inner surface of the scaphoid bone. It not unfrequently happens that the astragalus, being either insufficiently supported, or from

its being overweighted, descends slightly below its proper level, causing a lowering of the arch and a flattening of the sole of the foot. The defect when slight is known as 'weak ankle;' when more decided it is termed 'flat-foot;' and in extreme cases the bone may descend to such an extent as even to render the inner side of the foot convex when it naturally should be concave.

In the movements of the foot upon the leg we see a striking combination of variety of movement with general security. This combination is effected by the harmonious action of three joints, each of which acts in a direction different from the others. The first of these joints is the ankle-joint, which is formed by the bones of the leg—the tibia and fibula—above, and the astragalus below. At this joint the movements of *flexion*—i.e. approximation of the toes to the knee, and *extension*—i.e. pointing the toes to the ground, take place. The second joint is between the astragalus and the heel-bone, and it permits the foot to be rolled inwards or outwards; while the third joint is between the first and second row of tarsal bones—viz. between the astragalus and os calcis behind, and the scaphoid and cuboid bones in front—and allows the degree of curvature of the plantar arch to be increased or diminished within certain limits. The following is the order in which the movements of these three joints occur: the raising of the *heel* (by the first joint) is accompanied by a rolling of the foot *inwards* (by the second joint), and by an increased *flexure* of the plantar arch (by the third joint); and the raising of the *toes* is accompanied by a rolling of the foot *outwards*, and a *straightening* of the sole.

The joints, however, merely allow of movements; they do not effect them: this is the special function

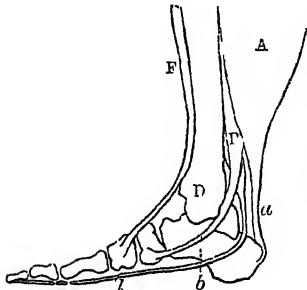

Fig. 3.

A, the gastrocnemius and soleus muscles, forming the muscles of the calf; a, the Tendo Achillis; B, the posterior tibial muscle, its tendon; D, the inner ankle; F, the anterior tibial muscle, attached above to the front of the tibia, below to the internal cuneiform bone; k, the flexor tendon of the great toe.

(fig. 3, B), attached above to the tibia, and below by its tendon to the scaphoid bone; and (3) the *short fibular* (fig. 4, C), attached above to the fibula, and below by its tendon to the outer metatarsal bone. The calf-muscles, whose tendon is inserted into the heel-bone, are large and very powerful, for in raising the heel they have to raise the weight of the body. The other two muscles, the posterior tibial and the short fibular, turn round the inner and the outer ankle respectively, and are inserted into the inner and the outer edges of the instep; the former being attached to the scaphoid, and the latter to the outer metatarsal bone. They not only assist in raising the ankle, but support it laterally. The muscle whose tendon is on the inner side of the foot (the posterior tibial)

effects the two movements which are associated with the raising of the heel-bone—viz. the turning of the foot inwards and the increased flexure of the arch.

The second series of movements—the raising of the toes, the turning of the foot outwards, and the straightening of the sole—are effected by two muscles, the *anterior tibial* (fig. 3, F) and the *third fibular* (fig. 4, G), whose tendons pass, one in front of the inner ankle, and the other in front of the outer ankle, to the corresponding edges of the instep, and are inserted into the internal cuneiform and the outer metatarsal bones. These muscles are direct flexors of the tarsus upon the leg; the former raising the inner, and the latter the outer border of the foot.

Another point in the anatomy of the foot that requires notice is the mode of union of the metatarsal with the tarsal bones. In these joints in the fourth and fifth toes a slight revolving motion can take place, which probably enables the outer metatarsals to adapt themselves to inequalities of the ground, and to equalise the distribution of the weight which is thrown upon the foot; while, in the corresponding joints of the three inner toes, scarcely any motion can occur—a provision by which additional strength is given to the inner side of the foot, upon which the weight of the body most directly falls.

The skin of the sole is very tough and strong; and intervening between it and the bones and the strong fascia of the sole of the foot is a thick pad of fat, which acts the part of an air or water cushion in defending the adjacent parts from injurious pressure, and in deadening the jars and shocks that would otherwise be felt in leaping, &c.

A few remarks on the subject of shoes may here be added. The shape of the sole of the natural foot is shown in fig. 5, while the shape after the prolonged use of a badly-made shoe is given in fig. 6. In the foot in its normal state the great toe is seen to be free from the others, and the line of its axis prolonged backwards passes through the centre of the heel; while in the foot distorted by the use of the shoe the line of the great toe is quite altered, and the toes generally—not being able to find room side by side—overlap each other

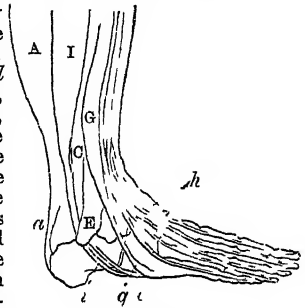

Fig. 4.

Fig. 6.

and lose their separate and individual actions; corns, bunions, and ingrowing toe-nails being the natural consequence of this maltreatment. Meyer

Fig. 7.

Shoe designed by Dr. Meyer, the dotted outline being the usual shape.

of Zurich drew attention to the bad treatment which the foot receives from ordinary shoemakers, and pointed out that the great toe should be allowed to have its normal position, and this can be done by making the inner edge of the sole incline *inwards*, instead of *outwards*, from the balls of the toes. The accompanying figure (7) gives the outline of a shoe designed under Meyer's superintendence, and shows the difference between it and the usual shape; the latter being indicated by the dotted outline. High heel-pieces tend to make the step less steady and secure, to break down the arch of the foot, to shorten it, and to impair the action of the calf-muscles. A high heel-piece, moreover, places the forepart of the foot at a lower level than the heel; the weight is thus thrown too much in the direction of the toes, and they are thrust forward and cramped against the upper leather of the shoe.

If we compare the human foot with the feet of other mammals we find that it presents certain peculiarities, all of which have reference to man's erect posture. The chief peculiarities are (1) the greater relative size of the tarsal bones as compared with the other bones of the foot, and the more perfect formation of the plantar arch, which is higher and stronger than in any of the lower animals. Strength and elasticity are thus combined in the human foot in the highest degree. (2) The great toe is remarkable in man for its size and strength, and for the firm manner in which its metatarsal bone is joined to the other bones so as to render it the main support to the foot. (3) If

Fig. 8.
Foot of Gorilla.

we compare the human foot with that of the gorilla (fig. 8) or any other Anthropoid Ape (q.v.) we see that the toes are short and small in man in relation to the other parts of the foot, while in the gorilla the toes form the greater part of the foot. Indeed, a reference to fig. 8 shows that the organ in question is rather a *hand* than a *foot*, and hence the term *quadrumanous* as applied to this class of animals. There is scarcely any plantar arch, and the weight of the body bears chiefly on the outer edge of the foot; the digits are long and strong, and the inner one diverges so as to form a thumb rather than a great toe.

It remains to notice some of the most marked varieties of form which the bones of the foot present in mammals. In the following group of figures the same letters are attached to the same bones. Thus, *a* marks the astragalus; *cl*, the calcaneum or heel-bone (the posterior projection of which forms the hook of the horse); *s*, the scaphoid; *b*, the cuboid; *ce*, the ecto- or outer, *cm*, the meso- or middle, *ci*, the ento- or internal cuneiform. Now, as a general rule in all mammalia, the ecto-cuneiform supports the third or middle of the five toes when they are all present, the meso-cuneiform the second, and the cuboid the fourth and fifth. Bearing in mind this law,

we see that the large bone in the horse, known as the cannon-bone, which is articulated to the

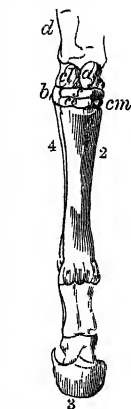

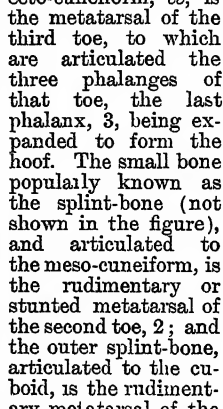

Fig. 9.—Horse. Fig. 10.—Ox.

in the horse we have only one toe, the third, sufficiently developed to reach the ground, with mere traces of a second and fourth toe on either side. In the foot of the ox the cuboid, *b*, is relatively larger than in the horse, and is equal in size to the ecto-cuneiform, *ce*. The cannon-bone articulates with both these tarsal bones, and hence answers to the metatarsal bones of both the *third* and *fourth* digits; it is accordingly found to consist of two distinct bones in the fetus; and in the adult it is divided internally into two cavities, and its original separation is marked out by an external elongated ridge.

Fig. 11.
Rhinoceros.Fig. 12.
Hippopotamus.Fig. 13.
Elephant.

At the lower end are two distinct joints for the phalanges of the third and fourth toes. While in the horse we had the rudiments of the *upper* parts of two toes (the second and fourth), in the ox we have the rudiments of the *lower* parts or phalanges of two toes (the second and fifth), forming the 'spurious hoofs,' and marked 2 and 5 in the figure. In the rhinoceros there is one principal toe (the third), as in the horse, with the second and fourth toes in a less developed state; while in the hippopotamus there are two principal toes (the third and fourth), as in the ox, with the second and fifth toes not fully developed. In the elephant there is a fifth digit added, answering to our great toe, and articulating with an ento-cuneiform bone, so that in the foot of this animal we have all the bones occurring in the human foot. Owen concludes from these and similar observations that the course of the simplification of the five-toed foot is, first, a diminution and removal of the innermost toe; next, of the outermost; then, of the

second; and lastly, of the fourth; the third or middle toe being the most constant and (in the lower animals) the most important of the five.

Foot, the most common unit of lineal measure all over the world, was taken originally from the length of the human foot. The three foot-measures that occur most frequently are the Paris foot or *pied de roi*, the (German) Rhenish foot, and the English. Compared with the French *mètre* (= 3·28090 English feet) they stand thus:

	Mètre.		English Inches.
English foot	= 0·30479	Paris foot	= 12·78912
Paris "	= 0·32484	Rhenish "	= 12·35652
Rhenish "	= 0·31385		

In round numbers, 46 Paris feet = 49 English feet, 34 Rhen. or Ger. feet = 35 English, and 57 Paris feet = 59 Rhenish. The Russian foot is almost exactly equal to the English. Many local feet are only about 10 inches. The foot has almost uniformly been divided into 12 inches, and the inch into 12 lines (often, however, into tenths). The French *pied usuel* is the third part of the *mètre* (see YARD, MÈTRE). In Music a foot is the short figure with one accent, and in Metre a grouping of syllables long and short, stressed and unstressed (dactyl, iambus, &c.).

Foot-and-Mouth Disease. See MURRAIN.

Football. Probably no game has ever been able to count upon so much popularity and so many opponents at one and the same time as the great English winter pastime of football. When it was first played it is impossible to say, but in one form or another the game has existed for very many centuries, in spite of an amount of opposition that would have completely extinguished a less attractive form of exercise. As in the case of cricket, and indeed many other ball games, opinions are divided as to whether football sprung up on English soil or was an importation. The Greeks had a game to a certain extent resembling football, which was played with the kind of ball known as *harpaston*, and one set of players had to force the ball into that portion of the ground guarded by a rival team in any way they chose. Amongst the Romans, too, there was a game played with a large inflated ball, the *foliis*; and, though it is evident this was only struck with the hand, yet the ball used was undoubtedly similar to the football of later years. No trace of the game as at present understood has, however, been discovered beyond the limits of Britain, where it has flourished for centuries. That football in its early days was played with a boisterous vigour which very closely approached brutality, and often led to breaches of the peace, ample proof is adduced by the numerous attempts made to prohibit it. As early as 1314 a proclamation was issued by Edward II. forbidding the hustling over large balls (*ragaries de grosses pelotes*), which it is to be presumed had reference to football. In 1349 the game, designated in the statute by its present name, was objected to by Edward III.; and similar measures were adopted with a view to its suppression by Henry IV. (1401) and Henry VIII.; while during the reign of Elizabeth the game was forbidden upon pain of imprisonment. Despite these prohibitive measures and much hostile criticism, football continued to be regularly pursued by the people at large until the middle of the 17th century, when it began to decline in popularity, the change being due possibly to the influence of Puritanism. It was not, however, allowed to die out altogether, and after being kept alive by the younger generation it ultimately became a regular item in the public school curriculum. This flame was fanned by the athletic revival of the 19th century, and before the century ended it was an

open question whether the votaries of football did not outnumber those of cricket.

The description of game played in the early ages was like that of the present day in that it consisted in forcing the ball through goals which were then defined by objects dependent upon the spot where the game was decided. The ball at the start was placed as now midway between the two goals, and each side, consisting of any number of players, endeavoured to gain the upper hand by any device or strategy. The game was played either in the street, on a field, or 'across country,' when in some instances the goals were several miles apart. Shrove Tuesday was the great football day. Until 1540 a game took place annually on this day on the Roodee, at Chester, and in some parts of England a game similar in character is still indulged in. The ball was kicked or thrown at the discretion of the player, and in the struggle to gain or retain possession of the ball there was some exceedingly rough work. A description of such a contest played as recently as 1888 was given in *The Field* of March 3 of that year. Joseph Strutt, writing in 1801, describes the game of that time, and by its close affinity it is evident that this was the prototype of the old hacking and tripping game, an early development of Rugby Union football.

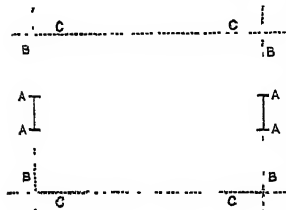

Football at the public schools was and is still of very varied character, the rules of the game having, as an admirable authority has suggested, been probably drawn up to suit the capacity of the playground. Where the ground, as at Rugby School, took the form of a large meadow, there running with the ball, the consequent tackling or collaring, and the rough tactics adopted in the primitive game could be indulged in without fear of serious danger; but not so in the circumscribed and more general kind of playground, with, in many cases, its flagged pavement. Here it was necessary that the rougher element should be eliminated; and hence arose the game in which kicking the ball was alone permissible, to be subsequently known by the name of Association football.

About the middle of the 19th century clubs began to be formed by old public school boys. The Sheffield and Hallam clubs, playing the 'dribbling' or non-handling game, were started in 1857; a year later the celebrated Blackheath Club was formed for the purpose of promoting the 'carrying' game; and in 1858 came the institution of the famous Richmond Club. Others of course followed, and in 1863 a praiseworthy attempt was made to determine upon one code of rules to govern all players. This attempt failed, but a body, to be ever afterwards known as the Football Association, was in the same year formed by the 'dribbling' clubs, who were numerically stronger than the followers of Rugby. The latter section was content to remain without organisation until 1871, when the Rugby Football Union sprang into existence. Under the management of the societies named, the game has improved and grown in marvellous manner, until it stands unrivalled in Great Britain as a winter pastime. International and all other kinds of matches are played, and so extraordinary is the popularity of football that on several occasions over 100,000 people have been known to attend a single match, while some of the many clubs organised as limited liability companies have declared fair dividends. These companies run teams of paid players, who throughout the season take part in Football League (formed in 1888) and Rugby League (formed in 1901) competitions respectively, the first-mentioned playing according to Association rules, and the latter under the code adopted by the Northern Rugby Football Union (started in 1895). Other matches are, of

course, played by these professional teams, including international games, except those arranged by the Rugby Union and by the Football Association for amateurs.

The diagram will give some idea of the field of play.

In Rugby Union football the area for play is usually 110 yards by 75 yards; each goal is composed of two upright posts exceeding 11 feet in height from the ground, and placed 18 feet 6 inches apart, with a cross-bar 10 feet from the ground. For a match the opposing sides number fifteen each, and are generally disposed as follows: one full back, four three-quarter backs, two half-backs, and eight forwards.

AA, goal-posts; BB, goal-lines;
CC, touch-lines.

In the Rugby Union game the four corners outside the lines marking the field of play are known as touch in goal.

13 to 14½ oz., is oval in shape. It must be hand-sewn, with not less than eight stitches to the inch. It is the object of each side to obtain as many tries or goals as possible. At the present time matches under the Rugby Union code are decided by points: a try equals three points; a goal from a try (in which case the try does not count), five points; a dropped goal (except from a mark or a penalty kick), four points; a goal from a mark or penalty kick, three points. A try is gained when a player touches the ball down in his opponents' in-goal. This is accomplished by a player, when not offside, dodging his opponents and crossing the goal-line at any spot. A player is put offside if he enters a scrumage from his opponents' side, or, being in a scrumage, gets in front of the ball, or when the ball has been kicked, touched, or is being run with by any of his own side behind him—i.e. between himself and his own goal-line. A side having so touched the ball down, one of the players of the same side must bring it up to the goal-line in a straight line from the spot where it was touched down, and thence walk out with it in a line parallel to the touch-lines such distance as is thought proper, and there place it for another of the side to kick. Should the ball be kicked directly over the cross-bar (not over either post) it is a goal. A goal may, however, be obtained by a drop-kick (made by letting the ball fall from the hands and kicking it the very instant it rises) at any time during the game; or from a place-kick (made by kicking the ball after it has been placed in a nick made in the ground for the purpose of keeping it at rest) or a drop taken as a free kick for a fair catch (a catch made direct from a kick, throw forward, or a knock on by one of the opposite side), or as an award for a penalty.

For Association football the most popular dimensions of ground are 120 yards by 80, and for cup-tie matches, which are exceedingly numerous, the field of play must not be less than 110 yards by 70. The goal-posts are placed eight yards apart, with a bar across eight feet from the ground.

In this game only goals count, and to obtain a goal the ball (27 to 28 inches in circumference, and weighing 13 to 15 oz.) must be passed between the goal-posts under the bar. No player is permitted to carry, knock on (strike or propel the ball with hand or arm), or handle (play the ball with hand or arm) the ball under any pretence whatever, except in the case of the goal-keeper, who, within his own penalty area, may use his hands in defence of his goal, either by knocking on or throwing, but not 'carrying,' the ball. A goal may be scored from a free kick awarded as a penalty for tripping, kicking, striking, or jumping at a player, handling the ball, holding or pushing an opponent, or charging from behind, but not from any other free kick. Matches are played between sides numbering eleven each, the players being generally disposed as follows: a goal-keeper, two backs, three half-backs, and five forwards. As at Rugby Union, the greatest factor towards success is the working together of the whole team.

In many parts of the world besides Great Britain football has of recent years spread in a remarkable way. In both France and Germany it has grown rapidly in popularity, but it has perhaps taken the strongest hold in Australia, New Zealand, South Africa, and Canada. Two games are played in Australasia, the one being strictly according to the English Rugby Union code, the other a combination of the two styles so well known in Great Britain. In the so-called 'Australian' game, which is played throughout Victoria, and to a small extent in some other states, the ball has to be bounded by the player while running, and in this particular the game differs from both Rugby Union and Association. New South Wales, Queensland, and New Zealand favour the Rugby Union game, into which they have of late years introduced minor modifications; but both games are exceedingly popular with the public, who muster in their thousands at the more important matches. Comparatively little Rugby Union is played either in Canada or the United States, but in both countries the Association game flourishes. Until the last quarter of the 19th century football was less known in the United States; but, under the New York and Paterson clubs, the game grew rapidly, and in April 1884 was formed the American Football Association. The game is very popular in the colleges and schools, where an elaborated form of the English Rugby is played; the ball is advanced by carrying, passing, or kicking, and the playing of the 'team' is regulated by secret signals. A variety of football is very popular with some Indian tribes, as the Washoes of Nevada. Visits to Great Britain have been paid by teams representing France, Germany, Australia, New Zealand, South Africa, Canada, and the United States, and in most cases return visits have been made.

Footie, ANDREW HULL, American naval officer, was born in New Haven, Connecticut, in 1806, entered the navy in 1822, and after some service against the pirates of the West Indies was appointed captain in 1849. In 1856 he gallantly carried by storm four Chinese forts at Canton, from which he had been fired on while protecting American property. On the outbreak of the civil war he equipped and organised the western flotilla, and in February 1862, with his gunboats, he stormed Fort Henry. At Fort Donelson, in the same month, he received a wound which soon afterwards compelled him to resign his command; but his services obtained for him the rank of rear-admiral and a vote of thanks from congress. He died in New York city, 26th June 1863, while on his way to take over the command of the fleet off Charleston.

Footte, SAMUEL, English actor and writer of comedy, was born at Truro, in Cornwall, in January 1720. His father at one time sat in parliament for Tiverton, and was mayor of Truro; his mother inherited a considerable fortune from her brother, Sir John Goodere, Bart., who was murdered by another brother. Footte left Worcester College, Oxford, without a degree, and about 1740 entered the Temple; but after wasting his fortune in a career of pleasure he turned to the stage as a means of support, and in 1744 made an unsuccessful début as 'a gentleman' in 'Othello.' In 1747 he opened the Haymarket Theatre—where he was at once director, actor, and dramatic author—with *Diversions of the Morning*. In this and other pieces he introduced well-known living characters, and by his admirable powers of mimicry succeeded in drawing large audiences; the theatre was closed by order of the magistrates, but Footte hit on the device of inviting his friends to 'a cup of tea,' for which tickets were to be obtained at the coffee-houses. He appeared in a great number of parts in London, Edinburgh, and Dublin, but would seem to have achieved success almost solely in his own plays. In 1766 he broke his leg by a fall from his horse, and amputation was found necessary. This, however, did not interrupt his career; he even turned the incident to account on the stage, by composing parts expressly adapted to his own state. He died at Dover on 21st October 1777. Of his plays the best are *An Auction of Pictures*, *The Minor*, *The Liar*, and *The Mayor of Garratt*, which have been frequently published. Many anecdotes of him, though not infrequently borrowed from earlier sources, are given in Cooke's *Memoirs of Samuel Footte* (1805); see also Forster's *Biographical Essays* (3d ed. 1860), Joseph Knight in the *Dict. of Nat. Biog.*, vol. xix. (1889), and a Life by P. H. Fitzgerald (1910).

Foot-guards, the flower of British infantry, ordinarily the garrison of the metropolis, comprise the Grenadiers, Coldstream, Scots, Irish (1902), and Welsh (1915) Guards. See GUARDS.

Foot-pound is the unit used to express the work done by any form of force. Thus, taking 1 lb. and 1 foot as the units of weight and distance, if 1 lb. be raised through 1 foot, the work done is equivalent to 1 foot-pound; and generally, if W represent the work done, P the weight in pounds, and h the height in feet, then W (in foot-pounds) = Ph .

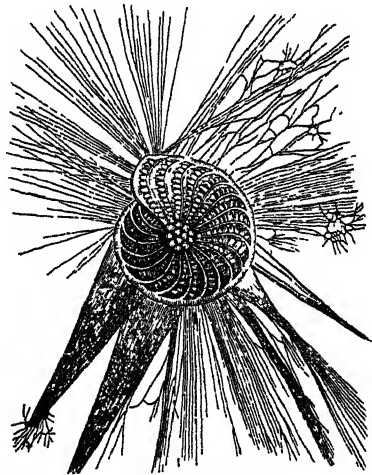

Footprints. See FOSSIL.

Foot-rot amongst sheep is of two varieties, the commoner and less troublesome often accompanied by an inordinate growth of hoof, which towards the heel becomes turned in, and at the toe or round the margin cracked or torn, and thus affords lodgment for sand and dirt. Insufficient wearing of the hoof is the obvious cause, and hence the prevalence of foot-rot in soft rich pastures, and especially amongst sheep previously accustomed to bare, rough, or upland walks, where the hoof is naturally worn down by the greater amount of walking necessary to procure sustenance. Taken in time, when lameness is first apparent, and before the hoof is cracked and the foot inflamed, a cure rapidly follows the careful paring of the superfluous and diseased hoof; indeed, further treatment is scarcely necessary unless any of the vascular parts have been laid bare, when a little tar may be applied as a mild astringent and protection from flies. When from inattention or neglect the hoof is separated from the sensitive parts beneath, when ulcers appear on the sole, or proud-flesh springs up, active astringents or mild caustics are necessary. The shepherd's old favourite butter of antimony, diluted with an equal quantity of tincture of myrrh, is a good remedy when cautiously and

temperately used. A convenient paste, which in inexperienced hands is safer than a fluid caustic, may be made with equal weights of flowers of sulphur and finely-powdered sulphate of copper, rubbed up to the needful consistency with lard or vaseline. Many have great faith in a mixture of the salt of copper with gunpowder and lard.

The second variety is allied to *foul* in the foot, and is contagious. The foot is hot, tender, and swollen around and immediately above the coronet. Ulcerations may arise in the interdigital space, and the swelling and subsequently the proud-flesh cause a spreading of the toes. In the milder cases and earlier stages the parts should be well washed with a solution of chloride of zinc, and in all cases the loose and semi-detached horn carefully removed, the parts thoroughly cleansed before applying the dressing, and in bad cases protected by a bandage. When ulcers appear they must be touched with lunar caustic or dressed with the paste already recommended. Or a foot-bath, 16 feet long and 8 inches wide at the bottom, with spreading sides to allow the sheep to walk through, is used with a 10 per cent. solution of sulphate of copper, or 1 part of sulphuric acid to 10 parts of water; a dry day should be chosen, and the sheep put on a bare road or causeway until their feet are dry. It should be used once a week if necessary.

Foraminifera, a class of unicellular animals or Protozoa, almost always marine in distribution, most characteristically provided with limy shells, which have formed the chalk of the past and are now forming similar deposits in the deep sea. A living Foraminifer, often about the size of a pin's

A living Foraminifer (*Polystomella strigillata*).

head, consists of a central nucleated mass of protoplasm, of a shell surrounding this, and of long, branched, and interlacing threads of living matter streaming outwards, with food-absorbing and locomotor functions.

Description.—The shell, which is much better known than its tenant, is characteristically calcareous, chambered, and covered with minute holes. But it is occasionally chitinous, and often arenaceous—i.e. composed of cemented particles of sand. At first a simple enough insheathing test, and so remaining in many forms, the shell is very generally added to, so as to cover successive overflows of growth. The ways in which fresh chambers are formed—in linear series, in spirals, and the like—produce types of architecture of great beauty and variety, as to the building of

which we can only conceal our ignorance by calling them organic crystallisations. The spirals often look like miniature sketches of the shells of Nautili, snails, and other molluscs. When partitions are formed between successive chambers they leave apertures through which bridges of protoplasm preserve the vital continuity. On the

Shells of various Foraminifera.

outer surface the outflowing protoplasm may reserve for itself one relatively large aperture, or a couple, or a few, but most characteristically there are numerous minute holes left all over the shell.

The internal protoplasm, so far as observed, is homogeneous, except for granules, frequent pigment, and the essential nucleus or nuclei. On the outflowing processes, which are more irregular and interlaced than is usual in Radiolarians, granules stream outwards and inwards in active currents. The pseudopodia effect locomotion, but are also very important in entangling the diatoms, infusorians, and the like which Foraminifera use as food. In the pelagic Foraminifera, such as the Globigerinids, the peripheral part of the protoplasm is abundantly vacuolated, and probably contains a fluid lighter than sea-water. In *Hastigerina*, one of the Globigerinids, there is a zone of much vacuolated protoplasm outside the shell. On the whole, however, the living part of Foraminifera seems to have a very uniform structure. Foraminifera multiply by fission or by spore-formation, and in some cases—e.g. *Patellina* and *Discorbina*—several individuals may unite closely before forming spores. Many—e.g. *Polystomella*—show a remarkable dimorphism, occurring in two distinct forms which differ notably in the size of the first chamber of the shell and as regards their nuclei. In these dimorphic species a complicated alternation of generations occurs. In a few cases—e.g. *Microgromia socialis*—a number of individuals are united to form a loose colony, a primitive kind of association exhibited by not a few Protozoa. Most modern forms are small, below half an inch in diameter, and many very much less, down to microscopic dimensions. The largest living species (*Cycloclippus carpenteri*) measures slightly over 2 inches across the shell, and recalls the extinct giant Nummulites, many of which were as large as half-crowns.

Distribution.—The Foraminifera are mostly marine, and occur at all depths; a few (Globigerinids), like the Radiolarians, are pelagic; most live on submerged objects or at the bottom. A few from brackish and even fresh water are known, and one species (*Gromia terricola*) has gone ashore. The pelagic forms as they die sink gently to the bottom, and are there forming,

especially at depths between 1000 and 2000 fathoms, great beds of Globigerina ooze or modern chalk. In other regions sandy-shelled forms predominate at the bottom.

In marine geological strata from the Silurian onwards Foraminifera abound. Chalk consists almost wholly of fossil Globigerinids, and the Nummulites have contributed largely to the great Eocene limestones. The animal nature of Eozoon (q.v.) from the pre-Cambrian strata is now generally denied, and is at least very doubtful.

Position and Classification.—The Foraminifera were so named by D'Orbigny in 1826, and placed beside the Cephalopods, to the shells of some of which the tests present a mimetic or prophetic resemblance. The title referred not, as might be supposed, to the superficial apertures on the shell, but to the communications between successive chambers. Hertwig would call them Thalamophora, in allusion to the typical chambered shell; while Carpenter emphasised the living network of processes in the title Reticularia. Accounting as they do the amœboid phase of cell-life, the Foraminifera have their place beside Amœbæ, Radiolarians, and Sun-animalcules in the Rhizopod division of Protozoa (q.v.). They were formerly classified as Perforate and Imperforate according to the presence or absence of numerous apertures on the test, but as this distinction separates apparently adjacent forms it is no longer generally adopted. By Brady, who has described the *Challenger* collection in a monumental monograph, they are classified in ten families, of which Gromia, Miliolina, Astrorhiza, Lituolina, Textularia, Chilotomella, Lagenella, Globigerina, Rotalia, and Nummulites are the name-giving types. In Gromia the shell is chitinous, flexible, and with a single aperture; in the related Shephardella there is an aperture at each end of an elongated test. The test of Miliolina is normally of lime, but in brackish water tends to become chitinous, and at great depths a siliceous film. Irregular sand particles form the primitive test of Astrorhiza, and the use of detached sponge spicules led to the related Haliphysema being mistaken for a very simple sponge. Among Lituolidae, Parkeria and Loftusia are relatively large forms—about two inches in diameter and length respectively. A peculiarly interesting *Challenger* form among the pelagic Globigerinids—*Hastigerina murrayi*—has the shell surrounded by a zone of bubbly protoplasm, and in its vacuoles and internal shell suggests Radiolarian characteristics. The species of Foraminifera are legion, probably above two thousand. They are interesting, as illustrating complexity and beauty of architecture at the very threshold of life, and important both in the making of the earth and in the present-day economy of submarine life.

See EOOZON, NUMMULITES, OOZE, PROTOZOA, RADIO-LARIA; Brady, *Challenger Report*, 1884; Butschli, *Protozoa* (Bronn's *Thierreich*); Carpenter, Parker, and Jones, *Introd. to Study of Foraminifera* (1862); Schultze, *Organismus der Polythalamien* (1854); Sherborn, *Bibliography* (1888); Chapman, *Foraminifera* (1902); Lister in Lankester's *Treatise on Zoology*, Part i. (1903).

Forbach, a manufacturing town of 8000 inhabitants, in Lorraine, 6 miles SW. of Saarbrück. Here on 6th August 1870 the French had to retreat.

Forbes, ALEXANDER PENROSE, bishop, was born in Edinburgh, the second son of Lord Medwyn, a judge of session, 6th June 1817, and spent the years 1837–40 in the East India Company's service, until ill-health compelled his retirement. He graduated at Oxford in 1844, was ordained in the same year, and in 1847, at the early age of thirty, was consecrated Bishop of Brechin, in Scotland, receiving the honorary degree of D.C.L. in 1848. A warm friend of Pusey, he delivered a charge in

1857 which was practically a manifesto on the manner of the Eucharistic Presence and on the nature of the Eucharistic Sacrifice; its publication raised a storm which culminated in its author's trial before the other bishops of the Scottish Episcopal Church in 1860, resulting in a 'declaration of censure and admonition.' Forbes died on 8th October 1875, more widely mourned than any Scottish bishop since the Reformation. He edited, with his brother, the *Arbuthnot Mussal* (1864), published with an elaborate preface *Kalendars of Scottish Saints* (1872), and was the author of valuable expositions of the Articles (2d ed. 1871) and Nicene Creed (2d ed. 1866), and of numerous other works, chiefly devotional. See *Memoirs* by Miss Skene (1876) and Canon Mackey (1888).

Forbes, ARCHIBALD, special correspondent of the *Daily News*, a son of the minister of Boharm, near Keith, was born in 1838. He was educated at Aberdeen University, and served for some years in the Royal Dragoons. But in 1870-71 he went through the Franco-German war as war-correspondent; and thenceforward, whether in Spain with the Carlists, in Cyprus, in the Russo-Turkish campaign, or in the Zulu war of 1879, he accustomed the British public to expect feats of unexampled audacity, swiftness, tact, and pluck in securing and transmitting his vivid first-hand notes of events at the front to his newspaper. A memorable exploit was his famous ride of 110 miles in 15 hours, in order to report at once the victory of Ulundi (1879). He had lectured in Great Britain, America, and Australia, and wrote a novel, *Drawn from Life* (1870), *Glimpses through the Cannon Smoke* (1880), *Chinese Gordon* (1884), and *Memoirs of War and Peace* (1895). He died 30th March 1900.

Forbes, DUNCAN, of Culloden, Lord President of the Court of Session, was born either at Culloden or at Bunchrew—for the family possessed both estates—in the neighbourhood of Inverness, on the 10th November 1685. In 1704 he commenced his legal studies in Edinburgh, and completed them at Leyden. On his return from Leyden he was called to the bar, and almost immediately after appointed Sheriff of Midlothian. He rose rapidly into practice and into political influence through his connection with the great Duke of Argyll. During both of the rebellions he acted a prominent part on the side of the Hanoverian government. In 1715 he was in the north actively engaged in opposing the rebels along with his elder brother John. After the suppression of the rebellion he was opposed to the project of carrying the prisoners out of Scotland to be tried by English juries; and he was opposed to the forfeitures also on grounds of policy as well as of humanity. The only effect of his moderation was to bring suspicion on his own loyalty. In 1725 he became Lord Advocate. He was not distinguished as a debater, but he was much employed at this period of his career in appeal cases. In 1734 his brother John died, and he succeeded to the estates of the family. During many subsequent years he largely ruled the destinies of Scotland and contributed to her dawning prosperity by fostering and developing her internal resources. His policy, even before 1745, was to extinguish the rebellious temper by gaining over the Jacobites to the government, and by forming Highland regiments under loyal colonels. Forbes was appointed President of the Court of Session in 1737; but he still continued his interest in the general improvement of the country. Though he was aware of the character and, in general, of the designs of the Jacobites, the rebellion of 1745 took him by surprise. But he was no sooner aware of the danger than he hastened to the north, as he had done on the occasion of the former out-

break; and by his presence and the influence which he possessed in his own district, he did much to counteract the proceedings of the rebels. Lovat's clansmen attacked Culloden House, but were beaten off with great spirit by the president and his people. When the rebellion spread he was compelled to take refuge in Skye; and on his return after Culloden, instead of reaping the fruits of his services, he was regarded with jealousy and aversion by the government. Even the large sums of money he had advanced were never repaid him. The ingratitude of the government and the disasters brought on the country by the rebellion shortened his days; but he discharged his judicial duties till within a month of his death, 10th December 1747. See Hill Burton's *Lives of Lord Lovat and Duncan Forbes of Culloden* (1847).

Forbes, EDWARD, naturalist, was the son of a banker, and was born at Douglas, Isle of Man, February 12, 1815. He received a desultory and imperfect education in early life in consequence of ill-health. In 1831 he went to London with the intention of becoming a student at the Royal Academy, but later in the same year entered the university of Edinburgh as a student of medicine; and in 1836 he finally relinquished his medical studies to devote himself exclusively to the natural sciences. In 1836-37 he studied at Paris under Geoffroy St-Hilaire, Jussieu, and De Blainville. From the first year of his college life Forbes had spent his summer vacations in rambles over various parts of Great Britain or in excursions on the Continent, publishing the results of the observations which he made either as separate works or in the pages of scientific journals. In 1841 he joined the surveying ship *Beacon* as naturalist, and accompanied that vessel during the survey of a part of Asia Minor. On his return to England in 1843 he became professor of Botany in King's College, London, and curator of the Geological Society. In 1844 he was appointed palaeontologist to the Museum of Geology in connection with the Ordnance Geological Survey; in 1851 professor of Natural History in the School of Mines; in 1852 president of the Geological Society; and in 1853, on the death of Professor Jameson, he was elected to the vacant chair of Natural History in the university of Edinburgh. In the summer of 1854 he delivered a short course of lectures—the only one he was destined to give—for at the commencement of the winter session he was seized with a severe illness, which speedily proved fatal; and he died on the 18th November 1854, in the thirty-ninth year of his age, and in the very zenith of his fame. Forbes had been a voluminous writer and a diligent observer of nature from his earliest youth, and had collected an immense mass of materials, many of which were, however, left at his death in a state of disorder. He did much to advance and systematise special departments of natural history, both by his own labours and by the stimulus which he imparted to his associates and pupils. His classification of the British star-fishes opened a new era in that branch of zoology; and his discovery that air-breathing molluscs lived at the period of the Purbeck beds rectified many erroneous hypotheses. From an early period he had directed his attention to the distribution of animal and vegetable life in different zones of the sea and land, and his observations in this path of inquiry have opened many new fields of research. Of his separate works, papers, and monographs upwards of two hundred were published, many of them copiously illustrated by his own beautiful drawings. Among them may be instanced the following: *On the Distrib. of Pulmonif. Mollusca in Europe* (1838), *Malacol. Monensis* (1838), *Star-fishes* (1841), *The Radiata and Mollusca of the Egean* (1843), *Travels*

in *Lycia* (in conjunction with Spratt, 1846), *Naked-eyed Medusæ* (1847), *British Mollusca* (conjointly with Hanley, 4 vols. 8vo, 1853), and *Collection of Literary Papers by E. Forbes* (1855). See the Memoir by G. Wilson and A. Geikie (1861).—His brother DAVID (1828–76) was distinguished as a geologist.

Forbes, JAMES DAVID, physicist, was the son of Sir William Forbes of Pitsligo, and grandson of the Sir William given below. Born at Edinburgh, April 20, 1809, he studied in the university there from 1825 until 1830, when he was called to the Scottish bar. But the physical sciences were from an early age serious rivals to the law in his affections. From 1833 he held the chair of Natural Philosophy in Edinburgh University, exchanging it in 1859 for the principalship of the United College in the university of St Andrews. Among his contributions to science are his investigations on the polarisation of radiant heat by the tourmaline, and also by reflection, and its circular polarisation (1834)—discoveries forming some of the strongest proofs of the identity of calorific and luminous rays; the unequal polarisation of heat from different sources (1844); the conductivity of heat by iron; the refrangibility of heat; the depolarisation of heat; underground temperatures, &c. He is, however, best known by his researches on the motion of glaciers, in connection with which subject he wrote *Travels through the Alps* (1843), *Norway and its Glaciers* (1853), *Tour of Mont Blanc and Monte Rosa* (1855), and *Occasional Papers on the Theory of Glaciers* (1859). He was the first to establish the great fact that glacier ice moves in its channel like a viscous fluid, the middle moving faster than the sides, and the upper portions faster than the lower. In meteorology Forbes, among other things, improved Wollaston's application of the thermometer to the determination of heights, and verified Fourier's theoretical results concerning the temperature of the ground at different depths and in different kinds of soil and rock. He also contributed numerous papers on astronomy and other subjects to the *Transactions of the Royal Societies of London and Edinburgh*, to the *Edinburgh Philosophical Journal*, and similar periodicals. He died December 31, 1868. See his *Life and Letters*, edited by Shairp, Tait, and Adams Reilly (1873).

Forbes, SIR JOHN, physician, was born about the close of 1787, at Cuttlebrae, Banffshire. After studying at Aberdeen and Edinburgh he entered the navy in 1807 as assistant-surgeon; in 1817 he took the degree of M.D. at Edinburgh; and after practising as a physician at Penzance and at Chichester he went in 1840 to London, where he speedily made a large practice. He was knighted in 1853 by the Queen, to whose household he held the appointment of physician in ordinary. He was F.R.S. and D.C.L. of Oxford, as well as member of numerous foreign societies. Conjointly with Drs Tweedie and Conolly he was the editor of the *Cyclopædia of Practical Medicine* (4 vols. 1832–35). In 1836 he founded the *British and Foreign Medical Review*, which he carried on for twelve years. To him in a great measure belongs the merit of having introduced the use of the stethoscope in England, and of having successfully directed the attention of British practitioners to the art and practice of physical diagnosis. He died 13th November 1861.

Forbes, SIR WILLIAM, of Pitsligo, an eminent Scottish banker, son of Sir William Forbes, Bart., advocate, was born in Edinburgh, April 5, 1739. In his fifteenth year he entered the bank at Edinburgh of Messrs John Coult & Co., and in 1761 was admitted a partner; and in 1763 a new company was formed of which Sir William Forbes

ultimately became the head. In 1781 he purchased the estate of Pitsligo, Aberdeenshire, which had been forfeited by Lord Forbes of Pitsligo for taking part in the rebellion of 1745. He published a *Life of his friend Beattie*, the poet, in 1805; also *Memoirs of a Banking House*, being the history of his own (1803; ed. by Robert Chambers, 1860). He died November 12, 1806. His bank became in 1830 the Union Bank of Scotland. One of his sons was John Hay Forbes, Lord Medwyn.

Forbes-Mackenzie, WILLIAM (1801–62), M.P. for Peeblesshire, whose name is known in connection with an Act introduced by him and passed in 1853 'for the better regulation of public-houses in Scotland,' prohibiting provision-merchants from selling excisable liquors 'to be drunk on the premises,' permitting public-houses to be open on week-days only between 8 A.M. and 11 P.M., and forbidding the sale of liquor in hotels throughout the Sundays save to lodgers and *bona-fide* travellers. See LICENSING LAWS.

Forbidden Fruit, or ADAM'S APPLE, a name fancifully given to the fruit of different species of Citrus, especially to *C. Medica*, var. *paradisi*, which has indentations in its rind suggesting tooth-marks. In Ceylon the same name is applied to the fruit of *Tabernaemontana dichotoma* (Apocynaceæ). The shape of the fruit suggests the idea of a piece having been bitten off, and the legend runs that it was good before Eve ate of it, although it has been poisonous ever since. See SHADDUCK.

Force. As employed in physical science, the term force means any cause which changes the direction or speed of the motion of a portion of matter. It is therefore correctly applied to a push or pull, to the weight of a body, the attraction exerted by a magnet on a piece of iron or by an electrified body on a pith-ball, &c. This is expressly laid down in the first of Newton's Laws of Motion—to wit:

Every body perseveres in its state of rest, or of uniform motion in a straight line, except in so far as it is compelled by forces to change that state.

Now, we find that we can, by conscious muscular exertion, set a piece of matter in motion, and also change its motion both in speed and in direction. Hence we figure to ourselves that we are exerting force upon it. But here great caution is requisite, as the direct impressions of sense are, in many cases, notoriously misleading. Until we know what Matter (q.v.) is, it is practically useless to speculate as to the precise nature of force, if indeed there be such a thing at all. Even Newton's language has an anthropomorphic character which it would be difficult to avoid without coining words for the purpose. Of course in Newton's system the force is assigned in direction and magnitude by the change of motion (i.e. of Momentum) said to be produced by it in a given time. This is the essence of the second law of motion.

And the third law greatly extends our view of the subject, for it points out that force is always dual:

To every action there is always an equal and contrary reaction, or the mutual actions between two bodies are always equal and oppositely directed.

But, as the results of the action and reaction alike are mere changes of momentum, and as neither can present itself without the other, all that we are logically entitled to say is that no change of motion takes place unaccompanied by an equal and opposite change. The introduction of the action and reaction may thus be merely an attempt to explain this observed interchange of momentum by the help of the sense-suggested notion of force.

There is no doubt that the introduction of the idea of force has been very useful, if only in

enabling us to express the fundamental laws of dynamics in a particularly concise and easily intelligible form. But there is equally little doubt that everything yet known on the subject can be perfectly well expressed without the use of the term force, or of the idea which it embodies.

The dynamical expression for which the term force has been introduced as a substitute presents itself in two forms, different in name and conception, but intrinsically the same—viz. the time-rate at which momentum (see DYNAMICS) changes, or the space-rate at which Energy (q.v.) is transformed or transferred. Thus, when a stone is let fall, the momentum which it acquires is proportional to the time of falling, so that after t seconds its amount is, say, At ; and in falling through a space of h feet it loses in potential energy, while it gains in kinetic energy, an amount proportional to the height fallen through, say, Bh . Experimental measurement shows us that A and B are one and the same quantity, and we say it represents the weight of the stone—i.e. the force under which we figure to ourselves that the fall takes place. It is very convenient to do so. But, except the indications of our muscular sense, we have no proof whatever that there is any reason for the fall of the stone other than the observed fact that energy has the property of preferring the kinetic to the potential form. And the statement that a stone of given mass has potential energy to a given amount, depending directly on its elevation above the earth, is sufficient (without even mention of weight, or of force in any form) to enable us to calculate all the circumstances of its fall. Though we have confined ourselves to an exceedingly simple example, a similar but of course more general statement as to energy enables us to make the calculation requisite for determining the motion in all cases, however complex.

Newton's definition of force has sometimes been amended (?) into 'Any cause which changes, or tends to change, the motion of a body.' But this is entirely foreign to his system. For his second law expressly says, '*Change of momentum is proportional to force, and takes place in the direction of the force.*' Hence, from Newton's point of view, there is no balancing of forces, though there may be balancing of the effects of forces.

The *Resultant* of two forces which act on the same particle of matter is defined as the single force which could produce in that particle the same change of momentum as would the two given forces if they acted jointly on it for the same period of time. As it follows at once from Newton's second law that different forces, acting for equal times on the same particle, produce velocities in their own directions and proportional to their magnitudes, the question of compounding these forces is the same as that of compounding the corresponding velocities. Hence we have at once the only correct basis for the proof of that *Parallelogram of Forces*, or *Triangle of Forces*, on which (from the so-called *statical* point of view) as much absolutely useless thought has been expended as upon Euclid's celebrated twelfth axiom and its consequences.

The true measure of a force is, of course, the amount of momentum which it produces in a given time. Hence, if our fundamental units of mass, length, and time be the pound, foot, and second, unit force is that which gives in one second a speed of one foot per second to a mass of one pound. This is the British absolute unit of force. As gravity produces a speed of about 32 feet per second during each second of the motion of a falling body, the unit force is (speaking very roughly) about $\frac{1}{32}$ part of the weight of a pound—i.e. about the weight of half an ounce. If we adopt the so-called C.G.S. system, in which the

units are the centimetre, gramme, and second, the unit force (called a *dyne*) is that which in one second produces a speed of one centimetre per second in a mass of one gramme. Compared with the British absolute unit, the dyne is very small, being little more than $\frac{1}{321600}$ part of it.

But the most startling of all the reflections on force and its ultimate nature which have perhaps ever been made are those of Faraday. Without calling in question in ordinary cases the truth of the conservation of energy, he endeavoured, by experiment (the only genuine test in a question so novel and so profound), to prove what may be called the Conservation of Force. Here we understand *force itself*, and not *energy*. He argues thus: Two masses, according to the undisputed law of gravitation, attract with four times their mutual force if their distance be diminished to half, and with only one-fourth of the same if their distance be doubled. He asks *whence comes the additional force in the former, and what becomes of the lost force in the latter case?*

Now, it is evident that this is a new question, totally distinct from any we have yet considered. To answer it, we must know *what* force is. Would gravitation have any existence if there were but one particle of matter in the universe, or does it suddenly come into existence when a second particle appears? Is it an attribute of matter, or is it due to something between the particles of matter? Faraday tried several experiments of an exceedingly delicate kind, in order to get at some answer to his question. A slight sketch of one of them must suffice. A pound-weight is not so heavy at the ceiling of a room as it is when on the floor; for, in the former case, it is more distant from the mass of the earth than in the latter. The difference for a height of 30 feet is (roughly) about $\frac{1}{321600}$ of its weight. Now, if a mass of metal be dropped through such a space, an additional force, $\frac{1}{321600}$ of its weight, is called into play; and the object of the experiment was to detect whether electrical effects accompanied this apparent *creation* of force. The mass, therefore, was a long copper wire, whose coils were insulated (see ELECTRICITY) from each other, and whose extremities were connected with those of the coil of a delicate Galvanometer (see GALVANI). Had any trace of an electric current been produced, the needle of the galvanometer would have been deflected; but, when all disturbing causes were avoided, no such deflection was detected. Other experiments with a view to the detection of other physical energies were also tried, but, like the first, with negative results only.

From what has been said above it is clear that we must not hastily conclude that there is such a *thing* as force, though we are in the constant habit of speaking about it. Our sensations are all more or less misleading until we can interpret them. The pain produced by a blow is quite a different thing from the energy of motion of a cudgel; and, when our muscular sense impresses on us the idea that we are exerting force, we must be cautious in our conclusions. For it is certain that force is *merely the rate per unit of length at which energy is transferred or transformed*.

Force and Fear are used as technical terms in the law of Scotland to denote that amount of constraint or compulsion which is enough to annul an engagement or obligation entered into under its influence. As consent is the essence of contracts, contracts entered into under compulsion are, in law, either (as some authorities say) void or (at lowest) voidable. But it is not every degree of constraint which will have this effect in law. As Bell states it (*Principles*, 12), the force and fear must be 'not vain or foolish fear, but such as to overpower a mind of ordinary firmness, or such as,

applied to a person of weaker age, sex, or condition, will produce the effect of overpowering violence on a firmer mind. Among the instruments of force and fear which have been held to annul engagement are threats and terror of death; pain to one's self, or one's parent or child; infamy and disgrace; imprisonment, when employed to obtain an advantage beyond the lawful object of it; and even loss of property.' On proof of force and fear the law restores the parties to the contract to the position in which they were before it was entered into, and will find the party employing it liable in damages as reparation for any injury done to the party constrained. The corresponding term in English law is *Duress* (q.v.). This consists in imprisonment or actual or threatened violence to the party himself, his wife, his parent or his child. An old distinction was drawn in criminal law as to *mayhem*—i.e. deprivation of a member proper for defence, as an arm, a finger, an eye, or a fore-tooth (but not a jaw-tooth, or an ear, or a nose, because these are supposed to be of no use in fighting). The distinction, however, is practically obsolete, and in any case has no application in civil matters. *Duress* renders a contract voidable, not void.

Forcellini, EGIDIO, Italian lexicographer. See FACCIOLOTTI.

Forceps (Lat., 'a pair of tongs or pincers'), the name given by surgeons to an instrument of great antiquity, used as a substitute for the fingers, and consisting of two levers of metal jointed together crosswise, nearer to one end than the other. The hand grasping the longer ends of the levers or handles closes the shorter ends, which are shaped so as to seize firmly the intended object. There is scarcely a surgical operation in which some form of forceps is not applied; and very numerous different shapes and sizes are made for different purposes. In addition to the forms used for the extraction of teeth (see DENTISTRY) there are, e.g., the *dissecting* forceps, which have roughened points, to lay hold of small portions of tissue which are to be divided by the knife; the *lithotomy* forceps, which have blades concave like spoons; and *fenestrated* forceps, which have apertures in the blades, and, as the soft tissues project into these, obtain a firm hold with less risk of tearing the parts. By means of Liston's *cutting* forceps a powerful hand can divide a great thickness of bone. But the most important of all are the *midwifery* forceps, an invaluable invention in cases of difficult delivery, which daily rescues from suffering and danger numerous mothers and infants. It was invented in the 16th or 17th century, probably by Peter Chamberlen, who, however, with his son and grandson, kept their method of facilitating delivery as a profitable family secret; and it did not become generally known to the medical profession till the first half of the 18th century. Numerous modifications of the instrument have since been introduced, but its main principle remains unchanged. It consists of two concave fenestrated blades, forming a cavity into which the head of the child fits. The blades are applied separately, one to each side of the head, and then locked together. Holding by the handles, the accoucheur aids the natural efforts of labour. The instrument does not necessarily or generally injure either mother or child.

Forcible Entry. According to English law any person who enters on property, in order to take possession of it, with violence or intimidation is guilty of a misdemeanour. It is immaterial whether the person so entering has a right to the property or not. If a person wrongfully in possession detains property by violence or threats he is guilty of the offence known as forcible detainer.

Forcing, in Gardening, is a term used to designate a process in which artificial heat is applied so that flowers, fruits, or other products of plants are obtained at a date or season other than that at which they may be had in the ordinary course of culture. The diminished light of the short days of the year is the gardener's chief obstacle. This in the case of forcing fruits taxes his skill to the utmost, because abundant light is essential both to the proper fertilising of the flowers and to the perfecting of the fruit. Some vegetables and salads and many flowers are, however, more successfully forced in the dark than in light. Rhubarb, sea-kale, mushrooms, lily of the valley, lilac, are all forced in greater or less darkness in order the better to develop their individual perfections. A purple lilac is preferred to a white one for forcing, because it not only comes out of the process a purer white, but with a greater substance than the latter. See GARDENING.

Ford, HENRY, American millionaire and pacifist, was born 30th July 1863 near Detroit, educated at a district school, and became a machinist. He early set himself the problem of producing cheap motor-cars, and in 1903 organised a company which ere long was producing, near Detroit and elsewhere, some 20,000 cars a week. A profit-sharing scheme was announced in 1914, with a minimum wage of five dollars a day, and provision was made for education, legal and medical advice, and other means of combining the men's welfare with efficiency. On the outbreak of the Great War he sent a peace ship on an unsuccessful mission to Europe, and strove hard against America's participation; but when his efforts failed, he threw his whole weight into the prosecution of the war. In 1918 he was Democratic candidate for the United States Senate in Washington, but was defeated. In 1919 he acquired the *Dearborn Independent*, a weekly with no advertisements. He came to be spoken of as a possible candidate for the presidency.

Ford, JOHN, dramatist, was the second son of Thomas Ford of Ilington, Devonshire. He was baptised at Ilington, 17th April 1586. After studying for a short time at Exeter College, Oxford, he became in November 1602 a member of the Middle Temple. His first work was an elegy on the death of the Earl of Devonshire, entitled *Fame's Memorial* (1606), with a dedicatory sonnet to Penelope, Countess of Devonshire (the 'Stella' of Sidney's sonnets); and in the same year he published *Honour Triumphant; or the Peers' Challenge . . . Also the Monarchs' Meeting; or the King of Denmark's Welcome into England*. He was writing for the stage as early as 1613, when his unpublished comedy, *An Ill Beginning has a Good End*, was acted at the Cockpit; but the first of his published plays is *The Lover's Melancholy*, produced 24th November 1623 and printed in 1629, a comedy of no particular merit. His most powerful tragedy, *'Tis pity She's a Whore*, acted at the Phoenix in Drury Lane, was published in 1633, with a dedicatory epistle to John, first Earl of Peterborough. To the same year belongs *The Broken Heart*, dedicated to Lord Craven. The closing scenes, deeply impressive but strangely fantastic, were passionately admired by Charles Lamb. *Love's Sacrifice* (1633), dedicated to the author's cousin, John Ford of Gray's Inn, is in parts excellent, but disappointing as a whole. Far more satisfactory is *The Chronicle History of Perkin Warbeck* (1634), dedicated to the Earl (afterwards Duke) of Newcastle. *The Fancies Chaste and Noble* (1638), dedicated to the Earl of Antrim, has an interesting but badly handled plot. *The Lady's Trial* (1638), had it been equal at all points, would have been a good play; it fails in the last act. *The Sun's Darling*, licensed for the stage in March 1623-24 and posthumously published in 1656, was

written in company with Dekker, who probably supplied the pleasing lyrical passages. Two other plays by Dekker and Ford, *The Fairy Knight* and *The Bristowe (Bristol) Merchant*, were produced in 1624, but were not published. *The Witch of Edmonston*, produced circa 1621 and published in 1658, was written with Dekker and William Rowley. Ford's share was probably confined to the scenes which relate to Frank Thorney. On one occasion Ford collaborated with Webster; but the tragedy, *A late Murder of the Son upon the Mother*, licensed for the stage in September 1624, was not given to the press. To Webster's *Duchess of Malfi* (1623) Ford prefixed a copy of commendatory verses. Among the plays unfortunately destroyed by Bishop Warburton's cook were four pieces by Ford, a tragedy, and three comedies. The tragedy, *Beauty in a Trance*, was entered in the Stationers' Register in 1653, and the three comedies, *The London Merchant*, *The Royal Combat*, and *An Ill Beginning has a Good End*, were entered in 1660; but all four remained unpublished.

After the publication (1639) of *The Lady's Trial* Ford passes from notice. There is a tradition that he secured a competence by his professional labours, and ended his days in Devonshire. It is certain that he was not dependent on the stage for his livelihood. In procuring practice he was doubtless aided by the influence of his maternal uncle, Lord Chief-justice Popham. Ford had little comic talent, but his place among the tragic poets is unassailable. There is often a want of spontaneity in his writings; he is too elaborate and too subtle; but his two great tragedies, *'Tis Pity* and *The Broken Heart*, are not far inferior to Webster's masterpieces. William Gifford edited Ford's works in 1827, Hartley Coleridge in 1840; in 1869 Alexander Dyce revised Gifford. An edition in Bang's *Materialien* was begun in 1908.

Ford, RICHARD, F.S.A., was born in 1796, graduated at Oxford in 1817, and was called to the bar, though he never practised. The years 1830-34 were spent in a series of long riding tours in Spain; and in 1845 appeared the first edition of his delightful *Handbook for Travellers in Spain*. His *Gatherings from Spain* (1846) is mainly made up of charming matter which want of space caused to be cut out of the second edition of the *Handbook*. For twenty years Ford was a contributor to the *Quarterly* and other reviews, and his papers on Spanish art especially are of great value. He died 1st Sept. 1858. See his *Letters* (ed. Prothero, 1905).

Fordun, JOHN OF. This early Scottish chronicler was a secular priest, perhaps connected with the cathedral of Aberdeen. It has been inferred from his name that he was born at Fordun, in Kincardineshire. Having proposed to himself the compilation of a chronicle of Scotland, he is said to have travelled on foot through Britain and Ireland in search of materials. He lived to write only five books of his *Scotichronicon*, bringing the history down to the death of King David I. in 1153. He left collections extending to the year 1384, about which time he is supposed to have died. The work which John of Fordun had left unfinished was resumed in 1441 by Walter Bower, abbot of the monastery of Austin Canons Regular, at Inchcolm, in the Firth of Forth. Making use of his collections so far as they went, Bower enlarged the five books which Fordun had completed, and wrote eleven new books, bringing the *Scotichronicon* down to the year 1437; but many of his alterations corrupted Fordun's narrative. The work is the chief authority for the history of Scotland prior to the 15th century; its value being greatest during the 14th, when it is contemporary. Of the *Scotichronicon* there exist upwards of twenty MSS.,

the purest as regards Fordun's text being that preserved in the Wolfenbüttele library. Four printed editions have been published. The latest edition of Fordun's own work is that chiefly from the Wolfenbüttele MS. edited by W. F. Skene (2 vols. Edin. 1871-72); one of the volumes being an English translation of the Latin text.

Forecasts. See METEOROLOGY.

Foreclosure, in English law, the process by which a mortgagor failing to repay the money lent on the security of an estate is compelled to forfeit his right to redeem the estate. Every person having mortgaged his estate is entitled to an equity of redemption, which can only be cut off by a formal process. For this purpose the mortgagee files a bill of foreclosure, praying that an account may be taken of the principal and interest due under the mortgage, and that the mortgagor, on failing to pay, may forfeit his equity of redemption. If on the day fixed for payment the money be not forthcoming, the mortgagor will be declared to have forfeited his equity of redemption, and the mortgagee will be allowed to retain the estate. See MORTGAGE.

Foreign Enlistment Act. In the law of England there was a statutory prohibition of enlistment in the service of a foreign prince from the times of James I.; but the statute commonly known as the Foreign Enlistment Act is that of 1870. It provides that if any British subject shall agree to enter the service of any foreign state at war with any friendly state, either as a soldier or a sailor, without the license of the sovereign, or an order in council or royal proclamation, or if any person within the British dominions induces any other person to enlist in the service of a foreign state, such person shall be guilty of a misdemeanour. The officers of the customs, on information on oath, may detain any vessel having persons on board destined for unlicensed foreign service. Masters of vessels knowingly having such persons on board are punishable by fine or imprisonment or both. Persons building any vessel for foreign service without license are guilty of a high misdemeanour, and the ship and stores are forfeited. Even to assist a foreign state at war with a friendly state by supplying warlike stores without license is a misdemeanour punishable with fine and imprisonment. These penalties are irrespective of any consequences that may follow to the individual for having committed a breach of international law. See MERCENARIES.

Foreigner. See ALIEN.

Foreign Law. The term foreign is applied by lawyers to places and matters outside the limits within which certain laws apply and courts have jurisdiction. Thus, to an English lawyer Scotland is a foreign country. Foreign law as such has, of course, no application to England; but the comity of nations requires that it should be recognised and acted upon in certain cases, as, for example, by the Extradition (q.v.) of offenders. The judgment of a foreign court, if in favour of the defendant, is an answer to an action brought on the same complaint in England; if in favour of the plaintiff, it is accepted as *prima facie* evidence that his claim is well founded, and he may obtain satisfaction by suing on the judgment in England. Foreign law is proved in an English court as a matter of fact by the evidence of experts, or, if necessary, by taking the opinion of a foreign court. Government is empowered to make treaties for facilitating mutual ascertainment of laws. The courts will not act on a judgment which seems to have been improperly obtained, nor will they enforce a foreign law which is not in

accordance with natural justice as we understand it. The foregoing rules are not peculiar to England; they are followed by the courts of other countries; French courts give effect to English judgments. See also CAPITULATION, CONSUL.—For Foreign Attachment, see ATTACHMENT; for Foreign Money, in law, see TENDER.

Foreign Legion (*Légion Étrangère*), a body of foreigners of all nationalities, many of them ne'er-do-wells and 'men with a past,' or even unmitigated blackguards, was recruited for the French service, organised at Toulon in 1831, and sent to assist in the conquest of Algeria, where in 1834, spite of severe losses in the field, their numbers rose to 5600; four battalions being German, one Spanish, and one partly Polish and partly Italian, engaged for from three to five years. In the Crimea 900 (out of 3200) succumbed. They fought well in Mexico and the Franco-German war, and in 1884 were reorganised in two regiments. It is stationed as required, and is under French officers. The discipline is very severe, and in some respects cruel. See (as well as Ouida's *Under Two Flags*) J. P. Le Poer, *A Modern Legionary* (1904), M. M., *Memoirs of the Foreign Legion* (1924).—In the Spanish Foreign Legion serving in Morocco, peculiarly barbarous conditions were reported in 1921.

Foreign Office. See SECRETARY OF STATE.

Forel, François Alphonse (1841–1912), was born and died at Morges, on the Lake of Geneva, of whose 'seiches,' geology, natural history, &c., he made a scientific study. He wrote *Le Léman* (1892–1902) and *Handbuch der Seenkunde* (1901).

Foreland, North and South, two promontories of England, on the east coast of Kent, between which are the Downs and Goodwin Sands. North Foreland, the *Cantium* of Ptolemy, which forms the north-east angle of the county, consists of chalky cliffs, nearly 200 feet high. South Foreland, also composed of chalk-cliffs, is 16 miles S. of North Foreland. It was off this part of the coast that the four days' sea-fight between Monk and De Ruyter took place in 1666. Both Forelands have lighthouses.

Forshore. See SEASHORE.

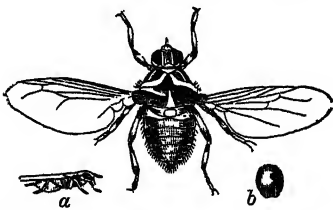

Foreshortening, a term in Painting or Drawing, applied to signify that a figure, or a portion of a figure, which is intended to be viewed by the spectator directly or nearly in front, is so represented as to convey the notion of its being projected forward; and, though by mere comparative measurement occupying a much smaller space on the surface, yet to give the same idea of length or size as if it had been projected laterally.

Forestalling. See ENGRESSING.

Forest-bed. See PLIOCENE.

Foresters. See FRIENDLY SOCIETIES.

Forest-fly, or HORSE-FLY (*Hippobosca equina*),

Forest-fly (*Hippobosca equina*), magnified:
a, natural size; b, the pupa, as deposited by the mother.

a Dipterous insect, parasitic on horses, oxen, &c.,

frequent in forests, particularly in the New Forest, Hampshire. It is a small insect, about four lines long, of a shining brown colour, with some yellow. Living on the blood of its host, it especially infests the tail, belly, and flanks. The insect passes the larval stage and becomes a pupa within the mother. One only is produced at a time, enclosed in a relatively large, black, bead-like, tough cocoon, from which the insect finally emerges by bursting open a kind of lid.

Forest Laws. Forest is defined by Coke to be a safe preserve for wild animals (*feræ*) of the chase. A forest, in the sense of the law of England, is a large tract of open ground, not necessarily covered with wood, but usually containing woodland interspersed with pasture, and forming part of the property of the monarch, and governed by a special code, called the forest law. This particular law not only had reference to matters connected with hunting and the like, but generally governed the persons living within the forest in all their relations. Though the privilege of forest belongs of right to the sovereign alone, it may be granted by him in favour of a subject, who becomes entitled to exercise the privileges of forest in the district assigned. This right was exercised by the Saxon kings. William the Conqueror greatly extended the royal forests, 'afforesting' and putting under forest laws vast districts in Hampshire and Yorkshire (but did not lay them waste or remove houses or churches); he also made several penalties for offences against the game.

The laws of the forest were first reduced to a code by the Forest Charter of 1217. Under William II., Henry I., and Stephen the cruel oppression increased for those whose lands were afforested; and Henry II. made extensive new afforestations, but was forced to relax the severity of the forest laws by passing a statute known as the Assize of Woodstock, 1184. This placed the forest law on a definite footing apart from the common law, and ordained that special forest courts should be held regularly for each forest—(1) the *Woodmote* or court of attachment, every forty days; (2) the *Swainmote* or court of freeholders, thrice a year, for inquiry; and (3) the *Justice-seat* or *Eyre of the Forest*, once every three years, a court of record and conviction, presided over by the chief-justice in eyre, acting as the king's commissioner. This was the highest forest official, though there were foresters and others attached to each royal forest; and no one could own a forest or appoint a forester except the king. In course of time irregularities and abuses crept in; and a detailed history of British forestry from about the end of the 11th to near the close of the 15th century would be a continuous record of attempted afforestations and reafforestations on the part of the kings, and of enforced perambulations of boundaries and disafforestation of usurped lands when the barons were strong enough to wring such concessions from the sovereign. Thus in 1215 Magna Carta modified the forest laws, and in Henry III.'s reign (1216–72) new charters were obtained; as also during the 14th and 15th centuries, when those holding land in or near a royal forest were subject to grievous oppression. The right of the sovereign to create a forest is by the common law confined to lands of his own demesne. Henry II. had arbitrarily exercised his power by afforesting the lands of his subjects; but by this charter of Henry III. it was provided that all forests so made should be disafforested. By the same charter the penalties for destroying game were greatly modified, it being provided that no man should lose life or limb for slaying deer, but that the punishment should be restricted to fine or imprisonment for a year and a day. Chap. 11 contains the following curious privilege: 'Whatsoever arch-

bishop, bishop, earl, or baron, coming to us at our commandment, passing by our forest, it shall be lawful for him to take and kill one or two of our deer by view of our forester if he be present; or else he shall cause one to blow an horn for him, that he seem not to steal our deer; and likewise they shall do returning from us.' Charles I.'s attempts to impose penalties and exact fines for alleged encroachments on the ancient boundaries of the forests, though the right to the lands thus taken was fortified by possession for several centuries, were among the first grievances with which the Long Parliament dealt. Since the passing of the act for the 'certainty of forests' (16 Car. I. chap. 16), the laws of the forest have practically ceased. The last Court of Justice-seat at which business was transacted was held in the reign of Charles I. before Lord Holland; the office of itinerant forest justices was not abolished until 1817, the criminal law of the forest having been almost wholly repealed half a century before.

In Coke's time there were sixty-nine royal forests; of these the principal were the New Forest, Sherwood, Dean, Windsor, Epping, Dartmoor, Wychwood in Oxfordshire; Salcey, Whittlebury, and Rockingham in Northamptonshire; Waltham in Lincolnshire; and Richmond in Yorkshire. Some of these were disafforested as recently as 1850, and now only four are preserved—Windsor and Wolmer as the exclusive property of the crown, New Forest and Dean with greatly circumscribed privileges, popular rights overshadowing crown rights. Scotland has many royal forests: in Perthshire, Athole, Glenartney, Glenfinlas, Glenalmond, &c.; in Aberdeenshire, the Stocket, Dyce, Kintore, Benachie, Drum, Birse, Braemar; in Forfarshire, Platan, Montrethmont, Kilgerry; in Kincaidine, Cowie and Durris; in Banffshire, Boyne and Enzie; in Elgin, Darnaway, &c. South of the Forth were those of Torwood, Cadzow, Ettick, Selkirk, Jedburgh, Traquair, the New Forest in Dumfriesshire, &c. The forest code of Scotland (*Leges Forestarum*), though neither so complete nor administered with the same rigour as that of England, was still generally complained of for its severe penalties and vexatious restraints. The grant of a right of forestry conferred the same privilege as if the ground over which it extended had been originally, and had continued to be, a king's forest. See DEER-FORESTS, FORESTRY, GAME LAWS, MAGNA CARTA, WOODS AND FORESTS; the articles on Dean, Epping, Sherwood, New Forest, &c.; Turner, *Select Pleas of the Forests* (1902); Cox, *Royal Forests* (1905).

Forest Marble, a member of the middle division of the Jurassic System (q.v.), of which the typical beds occur in Wychwood Forest, Oxfordshire. The principal bed is a fissile limestone, containing large numbers of dark-coloured shells, and capable of being polished and used as 'marble.'

Forestry is the science and art of forming and economically cultivating forests; practically the art of managing growing timber. It is accordingly rather *sylviculture* than *arboriculture*, but may be taken to include both branches.

The history of British forestry can best be understood from a brief survey of what took place in England. At one time the greater part of the British Isles was probably thickly covered with primeval woods, though most of our common timber-trees have been introduced; but even before the Roman period extensive clearances had already been made. In the Saxon and Danish periods the chief use of the woodlands was for hunting and for the pannage of great herds of swine, while wide tracts containing woods and other lands were here and there reserved as 'royal hunting-grounds.'

William the Conqueror acquired many such tracts, and he extended their boundaries and gave them the name of *forestae* or 'forests,' two of the largest being the New Forest in Hants and the Forest of Dean in Gloucestershire, both of which were formed before 1086. Lands thus reserved for the king's deer were said to be 'afforested,' and new 'forest laws' of a much more cruel and stringent character than had obtained before 1086 were applied to their administration. For the history of these forests, see FOREST LAWS. The office of chief-justice was not abolished by act of parliament till 1817, when his duties were entrusted to the First Commissioner of Woods and Forests. And now the existing remnants of these ancient royal forests are administered by the commissioners under an act of 1852. In Scotland forest laws framed on the English model, but nothing like so oppressive, were introduced at a comparatively late date, probably during the 15th century; while in Ireland, at a still later date, only arboricultural enactments seem to have had force, from 1634 onwards.

The planting of trees in Britain for utility or ornament certainly dates at least as far back as the Roman period, and most of our common woodland trees have been introduced, along with many others serving purely ornamental purposes, which grow well in our mild and equable climate, free from extremes of summer heat and winter cold. The indigenous kinds include common and sessile oak, ash, beech, hornbeam, Scots elm, white and goat willow, aspen, birch, alder, rowan, and cherry among broad-leaved trees, and Scots pine and yew among conifers; besides shrubs like field-maple, hawthorn, holly, juniper, &c. But to the Romans we owe the English elm, sweet chestnut, black and white poplar, lime, and service; while subsequent introductions date from much later periods—15th century, sycamore and crack willow; 16th, maple, plane, spruce, and maritime pine; 17th, silver fir, Canadian poplar, horse-chestnut, robinia, and larch (England); 18th, Weymouth and Corsican pine, and larch (Scotland); 19th, Austrian pine, Douglas fir, Menzies spruce, Monterey, Lawson's, and Nootka cypresses, giant arbor vitae, and Japanese larch; while in the 20th century, as yet, the American larch may perhaps prove to be the most important new species, with the hybrid (European \times Japanese) larch.

From this it would appear that from the 11th to the 15th century, while England was groaning under the worst tyranny of the oppressive forest laws, no important new kinds of timber-trees were introduced. But it is certain that arboriculture was habitually practised, and chiefly in the form of coppice with standards, long before the latter date. This seems clearly proved by the Statute of Enclosure passed in 1482, which applied only to the 'forests, chases, and purlieus' (or disafforested lands), and permitted landowners having woods within the same to fence their young coppices against deer and cattle for seven years after each fall, instead of only for three years, as had then apparently long been customary. But even at that early date there began to be great fear of a serious want of timber both for ship and house building and for fuel and firewood; and the great measure taken to obviate this danger was the passing of a Statute of Woods in 1543, of a compulsory and prohibitive nature, and applying to all the woods in the English realm. According to the rotation in which the coppice or underwood was worked (fourteen years or under, fourteen to twenty-four, and over twenty-four years), the falls were to be enclosed and fenced for four, six, or seven years; and on every acre of wood felled 'twelve standils or stoners of oak' had to be left, or, failing oak, then of 'elm, ash, asp, or beech,' to make up the number

of twelve standards per acre 'likely to prove to be timber-trees.' These were then the five most highly prized kinds of timber, and especially the oak for shipbuilding. But those provisions soon seeming inadequate, the time of enclosure was in 1570 increased by two years in each case.

About this time, during the Elizabethan period, considerable advances in forestry appear to have been made. In Taverner's *Book of Survey* of the royal forests in 1563 the 'setting' or sowing of acorns and beech-mast is mentioned (as regards the regeneration of old woods, see OAK and BEECH), and one of the first instances of thus also raising oak-woods where they were not already growing is said to have been thirteen acres in a corner of Cranbourne Chase, in Windsor Forest, about 1588 or shortly after that. Down to the end of the 16th century all the 'plantations' made were probably sown, while planting with live plants was only introduced early in the 17th century owing to the acorns and other tree-seeds being eaten by mice and voles, birds, &c. Thus Arthur Standish, in his *New Directions for Increasing Timber and Firewood* (of which the 2nd edition was issued in 1615), urged that, to obviate destruction of seed by field-mice, 'the remedy for such as would raise plants is by nurseries, where the mice may be destroyed by traps.'

All through the 17th and 18th centuries growing anxiety about timber for shipbuilding and other purposes necessitated close attention to forestry in all parts of the United Kingdom, and many acts of parliament were passed relating to woods and plantations; while in royal forests, and in the Forest of Dean in particular, regular schemes of management were introduced. So great was the scarcity of oak-timber in 1660 that the Commissioners of the Navy asked the advice of the Royal Society, and the result was the reading of a paper by John Evelyn on October 15, 1662, which was expanded and published as *Sylva, or a Discourse of Forest Trees*, in 1664, and which, passing into the 4th edition before the author's death in 1706, gave a great stimulus to planting for profit and ornament throughout Britain. And its influence continued all through the 18th and down into the 19th century, as numerous subsequent editions appeared (6th to 11th, 1786-1825), edited and annotated by Dr A. Hunter of York. The only other authors whose influence on British arboriculture has been at all comparable with Evelyn's are Sir Walter Scott and Loudon, during the first half of the 19th century.

It is noteworthy that one effect of the Statute of Woods (1543) and of subsequent modifying acts was to enforce a particular method of treatment of woods—namely, coppice or underwood consisting of oak, ash, hazel, chestnut, birch, willow, dogwood, &c., with standards of oak, ash, &c.—which thus compulsorily became the national form of British arboriculture. This secured for the standards of various ages in the copsewoods a free growing-space, enabling them to form large limbs and grow into crooked and curved timber suitable for shipbuilding. And so generation after generation of foresters and woodmen grew up in the firm belief that this was not only the best, but also the only suitable way of producing good timber of any kind whatever, with the result that in course of time, when highwoods also became a common method of timber-growing, there was a strong inclination to overthin greatly. This great and very usual fault of British arboriculture, down almost to the present day, was encouraged by the ruling idea that for the proper development of timber-trees the distance from stem to stem should equal one-third of their height—a generalisation which gives the same treatment to light-demanding trees like oak and larch, and to shade-enduring kinds like beech and spruce.

This specially arboricultural copsewood system continued to be practised with a considerable degree of regularity until well into the 19th century; and in its earlier years the English copses were among the most profitable portions of landed estates, as the underwoods also supplied hurdles, hop-poles, and small wood, everywhere in great demand and saleable at good prices. But as the market for oak-bark and small coppice-wood has changed completely, and is very poor now compared with what it used to be, many of the old coppices, with or without standards, have been converted into highwoods, in which the main object is to grow trees having large, long, clean stems.

The highwood method of timber-growing became considerably extended when large plantations of larch and other conifers were made in Britain about the middle of the 18th century, and in Ireland about the end of it. During the first half of the 19th century, however, the old national system of arboriculture began to decline, and became almost a lost art so far as regularity in storing and thinning out the different age-classes of standards was concerned. After Britain obtained command of the seas cheap foreign timber could be imported to any extent necessary, and less attention was paid to the woodlands. The decline was more rapid when steam communications improved by land and water. The growing neglect of the woodlands increased when the import-duty was taken off colonial timber in 1846, and became intensified when the import-duty was also removed from all foreign timber in 1866. Teak and iron were ousting oak for shipbuilding, cheap and good coniferous timber and sawn wood were apparently obtainable in inexhaustible abundance, and the value of home-grown woodland produce of all sorts fell so low that timber-growing, for centuries an important rural industry, became unprofitable, and many of the existing woods and plantations came to be practically treated as game-coverts and ornamental parts of the large landed estates.

Since 1866, however, the year in which what has proved a death-blow was given to the old system of British arboriculture, the great economic changes throughout the world have profoundly affected the question of Britain's timber-supplies. The vast increase in population and the enormous industrial development that have taken place in America since the reconstruction of the United States, and in Germany since the union of the empire in 1871, made these two formerly wood-exporting countries our keenest competitors for the surplus supplies of the great timber-producing tracts in Canada, Scandinavia, and Russia. But even in these still well-wooded countries there is less timber now available than formerly, and the cost of extraction is greater, so that prices have risen greatly and have constantly an upward tendency. Hence the importance of trying to improve British forestry and to adopt some well-considered national scheme of timber-planting throughout Britain, in order to increase work for our rural population, and to ensure the steady supply of our annual requirements in timber and other wood in years to come, has engaged the attention of government. Although the British Empire contains the largest and the most valuable forests in the world, Britain itself is one of the most poorly wooded countries. In 1915 its woodland area was about 3,098,000 acres, of which 1,730,000 acres were in England, 188,000 in Wales, 880,000 in Scotland, 300,000 in Ireland.

Much has recently been done for the improvement of British forestry and for the instruction of the public in matters relating thereto, and in urging government to deal with the timber question, by the Highland and Agricultural Society of Scotland,

the Royal Society of Arts, the Royal Scottish Arboricultural Society (1854), the Royal Arboricultural Society of England (1881), and the Irish Forestry Society (1901); and it was mainly to their efforts in these directions that a number of official inquiries and reports were made in 1885-1918. But so far as planting is concerned, only very little practical result followed. Small sums were granted and lent, chiefly for education, from the fund made available by the Development Act (1909). The Great War made foreign timber difficult to get, and British woods were felled so lavishly that the problem became acute. In 1919 a Forestry Act was passed, by which a Forestry Commission was set up, charged with the duty of promoting the interests of British forestry generally. The functions of the English and Scottish Boards of Agriculture and the Irish Department of Agriculture, so far as they related to forestry, were handed over to the commission, which is empowered to acquire land for afforestation; promote the sale, utilisation, and conversion of timber; make grants and loans to persons and local authorities for afforestation (including replanting); manage forests or advise on management; set up and carry on forest industries; collect statistics; establish and aid schools; promote research; prevent damage by rabbits, hares, and vermin. Greater facilities for instruction in modern forestry are required, especially in Scotland, where there is greatest scope for timber-growing. A course, for the most part in Continental forestry, was instituted in 1885 at Cooper's Hill, but transferred in 1905 to Oxford University, where probationers are trained for the Indian Forest Service and for forest appointments in the crown colonies. Other university centres at which lectures are given include Edinburgh (1889), Newcastle (1891), Bangor (1904), Cambridge (1907), and Dublin (1913), the most comprehensive courses being at Edinburgh and Cambridge; while somewhat similar instruction is provided at various agricultural colleges. In some cases degrees (B.Sc.) are granted, in other cases diplomas or certificates; and certificates in forestry are also given after special examinations by the Highland and Agricultural Society of Scotland and the Surveyors' Institution, London. For the training of young woodmen a forest school was opened for England and Wales in the Forest of Dean, Gloucestershire, by the Commissioners of Woods and Forests in 1904, and in 1905 a similar forest school for Ireland was organised at Avondale, Co. Wicklow, on an estate acquired along with adjoining woodlands for this purpose by the Department of Agriculture and Technical Instruction.

The probationers trained at Oxford, Cambridge, or Edinburgh for the Indian Forest Department go out as officers in the Imperial Forest Service, while officers of the Provincial Forest Services are trained at the Indian Forest College at Dehra Dún (United Provinces), and members of the subordinate staff (foresters, &c.) are taught at local forest schools organised in different provinces. Since the formation of the Indian Forest Department in 1863 great progress has been made in the administration and development of the vast forests yielding a large revenue. In most of the self-governing dominions, however, it is only of recent years that attention has been given to the conservation of timber-growing lands, and most of them have organised a forest service similar to that in India. Canada was the first dominion to establish a chair of forestry (at Toronto 1907). In several of the crown colonies and protectorates (Ceylon, Federated Malay States, Kenya, Nigeria, &c.) the forest administration follows the lines of the Indian model, though on a much smaller scale.

The modern forestry now taught at university

and collegiate centres has been to a great extent adapted from the Continental systems, in so far as they apply to the very different economic conditions obtaining in Britain. Like every other art concerning the cultivation of the soil, the natural sciences form its foundations; and it is advisable that a student should have a fair knowledge of chemistry, physics, climatology, geology, elementary soil-science, botany, and zoology before commencing the study of forestry itself, in which these and other sciences come into play. This modern art of forestry is usually divided, for convenience in teaching or studying it, into four main branches, with an *Introduction*: (1) *Sylviculture*, (2) *Management*, (3) *Protection*, and (4) *Utilisation*.

The *Introduction* should make a brief survey of the history of arboriculture in the United Kingdom, then indicate the direct and indirect utility of extensive woodlands with regard to climate, atmospheric and soil moisture, water storage and purification, and also to the employment of rural labour.

The *climatic and physical effects* of large compact blocks of woodland consist in tending (1) to equalise the temperature both of the soil and of the atmosphere, and to diminish extreme differences in each of these during summer and winter; (2) to increase the relative humidity of the air, and also perhaps slightly increase the total amount of dew, mist, and rainfall; (3) to absorb and retain moisture in the soil, and especially in the upper layer of humus, thus helping to prevent floods, to maintain the perennial flow of springs and brooks, and to act as purifying filters in water-catchment areas; (4) to protect the surface-soil from erosion during heavy rainfall; and (5) to help to purify the air from excess of carbon dioxide. Their *economic uses* are (1) to provide work for part of the rural population, and especially during winter, when other work is scarce; (2) to provide part of the timber now imported in vast quantities for industrial purposes, and thus increase the sum-total of wages payable to workmen in our own country; (3) to give shelter to fields and farm live-stock; and (4) to add to the attractions of country life by increasing facilities for sport. On the average one permanent woodman is required for every hundred to one hundred and fifty acres of woodland; but this gives no indication of the total amount of employment of various kinds that large woodlands worked on business principles would ensure to the rural population in planting, tending, and felling timber-crops; in preparing, extracting, transporting, and converting the timber; and in distributing the converted timber and other woodland produce. Any great national scheme of planting would ultimately mean that many millions of pounds sterling would annually be circulated among our own rural population in place of being sent abroad as at present. Even 3,000,000 acres of well-managed coniferous timber-crops worked with a rotation of sixty years would give an annual mature fall of 50,000 acres, besides thinnings in younger woods, and would probably yield on the average a total crop of about 100 tons weight of timber per acre, or about 5,000,000 tons of raw material having to be cut, dressed, transported, converted, and distributed.

1. *Sylviculture* deals with the formation, tending, and reproduction or regeneration of woodland crops, whether coppices, simple or stored (*sylvia cœdua*; see COPSE), or highwoods (*saltus*) of any description, between which two different classes of woods and plantations there are important legal distinctions (especially with regard to entailed estates in England). Unless this main branch has been preceded by a course of forest botany, consideration has first to be given to the woodland trees and their sylvicultural characteristics; their relation to

soil, climate, aspect, and environment; their relative demand for light, or capacity for enduring shade; and their rate of growth and suitability for growing in pure and in mixed woods. Coppices worked with a rotation of twelve to twenty years or so can be naturally reproduced by felling close to the ground, and standards may be stored, or the whole may be interplanted for conversion into highwood; while mature highwoods can either be naturally regulated by seed shed from parent trees (as is customary with beech, and less frequently oak, ash, sycamore, and Scots pine), or else clear-felled and a new crop raised artificially by sowing or planting. Owing to the rank growth of weeds in our damp climate the Continental methods of sowing are generally quite unsuitable, and planting is therefore customary, the young plants required being raised in nurseries (see the article *TRANSPLANTING*). Woodland planting of any sort can only be successful when there is a favourable combination of the following five factors: (1) suitable soil and situation, with such drainage and other soil-preparation as may be necessary; (2) suitable kinds of trees for the given local conditions, and of a suitable size and quality; (3) a suitable method of planting and number of plants per acre; (4) adequate protection against human actions, weeds, live-stock, game, and vermin for some years till the young plantation has thoroughly established itself; and (5) immunity from serious damage by frost, wind, drought, fire, fungus disease, &c. With regard to their timber, woodland trees are classified as hardwoods (oak, ash, elm, &c.), softwoods (willow, poplar, alder, &c.), and conifers. Of these the conifers are usually the most suitable for planting for profit on poor land, because they are generally less exacting as to soil and climate, harder and more capable of accommodating themselves to their environment, quicker in timber production, and on the whole more easily disposed of; whereas hardwoods usually need a fairly good class of soil, or at any rate one that has already been enriched with humus, for their profitable growth. And in any case wet land has to be thoroughly drained and prepared before planting (even if only by cutting small drains and inverting thick sods at the given planting-spots), as there is always great risk in altering the water-level in the soil carrying a timber-crop. But the future profit of any plantation is directly affected by the mode of planting, the size of the plants, and the distance at which they are set, as these mainly determine the initial cost, with beating-up until the plantation establishes itself. Two methods of planting have hitherto been customary in Britain, *notching* or *slit-planting* by making L or T shaped or other incisions in the sod, and then slipping in the plants—the cheapest method, but only suitable for a very light and friable soil; and *pitting* or opening out pockets of soil, and then replacing it carefully around the roots of the plant inserted. The cheapest way of opening pits is with a semicircular spade, of which several kinds are now in use. Whether naturally regenerated woods or artificial plantations should be pure or mixed depends on circumstances; but as a rule mixed woods are best, the mixture taking place in the natural method of groups of varying sizes specially suited to differences in soil, aspect, &c. Formerly planting was commonly done on a stencil-like 'planter's scheme'—e.g. hardwoods every eight or twelve feet—and filled up with larch, pine, &c. as 'nurses'; and often the nurses were left after they should have been thinned out, so that the ultimate wood was very different from what had been originally intended. With regard to tending woodlands, instruction is given as to weeding and cleaning of young crops, and the thinning of those that have arrived at or are getting beyond the polewood stage

of growth. The natural tendency hitherto to over-thin has already been alluded to, and the fact was also indicated that light-demanding trees like oak, ash, larch, or pine require somewhat heavier thinning than shade-enduring kinds like beech, Douglas fir, spruce, or silver fir; and, of course, the necessity for thinnings and the extent to which they are at any time desirable depend on local conditions. These also regulate the chance of profit in partially clearing and underplanting a maturing crop—a measure seldom likely to be profitable here.

2. *Management* deals with the best adjustment of the *capital*, represented by the land and the growing timber-crops of all ages, and the *income*, represented by the annual increment in wood accruing throughout all the woodlands on any estate, so as to be able to indicate the best and most profitable way of carrying out the proprietor's wishes, while at the same time safeguarding the capital and utilising the increment as fully as possible. This is rendered all the more difficult from the fact that part of the capital employed in production (the immature timber-crops) is of the same description as the wood produced for sale. This is also true of banking, and there would be hopeless confusion in a bank business without daily balancing of books and verification of balances. Something of the same kind has to take place if woodlands are to be managed on scientific principles. The proper amount of capital in growing timber for the given land forming any working-circle must be fixed, and the probable annual increment accruing thereon must be calculated to ascertain the proper annual fall. This can be roughly done by simple subdivision of the total area into equal or equally productive annual or periodic falls according to the number of years in the rotation; but where more scientific and systematic methods are adopted (after Continental models), a *working-plan* has to be compiled after making a register of all the crops, taking stock of their respective age, condition, cubic contents, and annual increment per acre, and arranging them into their proper age-classes, which can also be shown on a coloured 'stock map' (odnance survey, 6 inches to the mile is best). A wooded estate would be in an ideal or 'normal' condition if it had a normal succession of crops of all ages, each having a normal density and a normal increment, and having the annual falls normally distributed over the whole area; for then there would be a normal growing-stock or capital in wood, and a normal annual increment proportionate to the quality of the land and giving an equal income from year to year. But this ideal condition can never be attained, nor could it be maintained; and the object of a working-plan is so to adjust the given conditions of soil, growing-stock, and annual increment as may best suit the objects aimed at by the proprietor; the specific recommendations as to felling, thinning, and planting being usually made for the next ten years or more, when a revision is advisable. In the *valuation* of woodlands for succession-duty, rates and taxes, &c., the various acts of parliament regulating these imposts prescribe the manner in which they are to be assessed; but for all ordinary purposes exact actuarial methods have to be followed, as in all other money calculations. And as the rate of interest affects these considerably, 3 per cent. ought to be usually adopted for forestry.

3. *Protection* is provided by means of special forest laws in all countries having extensive woodlands; and this was formerly the case in Britain to a far larger extent than now obtains, when theft of and injury to trees, woods, shrubs, &c. are dealt with under the Larceny and Malicious Injuries Act of 1861. Accidental damage from railway fires is provided for in the Railway Fires Act, 1905,

operating from 1908. But in addition to protection against human actions, woodlands need to be protected against game (red deer, roe-deer, hares and rabbits, blackcock, &c.), vermin (squirrels, mice and moles, and insects), weeds, epiphytes and parasitic fungus diseases, frost, wind, and various other injuries arising from inorganic causes; and this main branch of forestry teaches the best way of preventing these different kinds of danger (so far as possible), and how any damage done can best be remedied.

4. *Utilisation* deals with the technical properties, practical uses, and market value of the different kinds of timber, the best way of felling and preparing it for sale, of transporting it by land and water, and of preserving it by seasoning and antiseptic processes. And it also treats of special woodland industries, such as estate and other sawmills, the preparation of wood-pulp and cellulose, charcoal-burning, resin-tapping, and grazing in woodlands, about all of which—and especially about small sawmills—it is desirable that the forester should know something.

It is, however, very important that such a theoretical course of instruction should be supplemented by frequent excursions to, and also by residence in, woodland estates.

See the numerous articles on the several trees and their management—oak, ash, elm, beech, birch, fir, pine, chestnut, walnut, willow, plane, hornbeam, &c.; teal, ebony, mahogany, eucalyptus, palm, &c.; also *WOOD* and *TIMBER*, and the following books. Nisbet's *The Forester* (1903) and *The Elements of British Forestry* (1911), Forbes's *English Estate Forestry* (1907), and Maw's *The Practice of Forestry* (1909) are the chief books on British arboriculture; while Schlich's (and Fisher's) *A Manual of Forestry* (various editions) deals mainly with German conditions.

Forez, an old division of France, in the Lyonnais, now included in the department of Loire. The capital was Montbrison. The Forez mountains in the west, between the Loire and the Allier, reach 5381 feet in Pierre-sur-Haute. The east is a plain, through which flows the Loire.

Forfar, the county town of Forfarshire, 14 miles NNE. of Dundee, stands at the east end of Forfar Loch, on a rising ground in the fertile valley of Strathmore. It was a royal residence as early as the reign of Malcolm Canmore, whose son, David I. (1124–53), made it a royal burgh; but in 1308 Bruce captured and razed the castle—its site is marked now by the town cross of 1684. Forfar, says Boece, was brought in 1526 to little more than a country village; but since the middle of the 18th century it has risen again to a comfortable town, with several good public buildings, among them a striking Episcopal church (1811). The making of brogues by the 'Forfar souters' is a thing of the long past; and linen is now the leading manufacture. With Montrose and three other burghs it returns one member to parliament. Pop. 10,000. Glamis Castle, a stately château-like pile, the seat of the Earl of Strathmore, lies 5 miles WSW.

Forfarshire, or **ANGUS**, a maritime Scottish county, washed on the east by the North Sea, on the south by the Firth of Tay. It has an utmost length and breadth of 36 and 36½ miles, and an area of 870 sq. m. The surface is finely diversified, the rich plain of Strathmore—the Howe of Angus—dividing the Sidlaw Hills (1399 feet) from the Grampian Braes of Angus in the north-west, which culminate in Cairn na Glasha (3484 feet) on the Aberdeenshire boundary, and exceed 2000 feet in twenty-two other summits. The chief streams are the North and South Esks and the Isla; and Loch Lee (9 by 2 furlongs) is the largest of several small lakes. The rocks are Silurian in the north-west,

and elsewhere Old Red Sandstone; the soils are very various. Somewhat less than half of the entire area is in cultivation, and more than one-nineteenth under wood. Agriculture is practised on the best methods, and much attention is paid to live-stock, though the celebrated 'polled Angus' belongs now specially to Aberdeenshire (see **CATTLE**). Linen and jute are the staple manufactures of the towns. These include Dundee, Montrose, Arbroath, Brechin, Forfar, Kirriemuir, and Carnoustie. The county returns one member to parliament. Pop. (1801) 99,053; (1881) 266,360; (1921) 270,950. Part of Southern Pictavia, then till 1242 the *mormaer*-ship or old Celtic earldom of Angus, Forfarshire is rich in antiquities—vitrified and other hill-forts, cairns and standing-stones, Roman camps, the sculptured stones of Meigle, Aberlemno, St Vigean, Glamis, &c., the ruins of Restenneth priory and Arbroath abbey, the round tower and cathedral of Brechin, and the old castles of Glamis, Edzell, Finhaven, Airlie, &c. See A. Jervise's *Memorials of Angus and Mearns* (1861), and *Land of the Lindsay* (2d ed. 1882); and Warden's *Angus or Forfarshire* (4 vols. 1880–83).

Forfeiture is a legal term which includes the various cases in which a person is penally deprived of property. An offender who is fined forfeits a sum of money, which is recovered out of his general estate. The feudal law of England made forfeiture of land and goods part of the punishment of an offence involving disloyalty or breach of feudal duty; thus, the lord might claim lands in case of what was called 'escheat with attainder,' and there was forfeiture to the king in case of treason. An act of 1870 abolishes forfeiture in case of conviction for treason and felony; but the crown may appoint a person to administer the property of a convict; compensation to parties injured, and the costs of the prosecution, may be paid out of his estate. Civil forfeiture of land may still be incurred by unlawful alienation in Mortmain (q.v.), or by breach of the conditions on which the property has been acquired. A tenant, for example, may incur forfeiture by breach of his covenants, or by wrongful disclaimer—i.e. setting up a claim adverse to that of his landlord. Forfeiture for tortious alienation (i.e. for attempting to convey an estate greater than the grantor is entitled to) is now obsolete. The courts will always lean against a forfeiture, and the Conveyancing Act, 1881, protects a tenant against this extreme penalty where compensation in money meets the justice of the case.

In Scotland civil forfeiture may arise either from statutory enactment, at common law, or by agreement. By 1597, chap. 246, it is enacted that vassals failing to pay their feu-duties for two years shall forfeit their right. This forfeiture must be established by an action to recover the feu-duties in arrear, and may be avoided by payment at the bar. At common law a vassal forfeited his land by disclaimer or purpresture. The former is analogous to the English disclaimer, and consists in the denial by a vassal of his lawful superior. Purpresture was incurred by the vassal's encroachment on the streets, highways, or commons belonging to the crown or other superior. These forms of forfeiture are fallen into disuse. Forfeiture on special agreement depends wholly upon the terms of the condition inserted in the titles to the land. The condition must be fortified by irritant and resolute clauses, and must enter the sasine, in order that it may be effectual against purchasers of the lands. Of this kind of forfeiture are breaches of Entails (q.v.). See **ATTAINDER**, **TREASON**.

Forgery (Fr. *forger*, 'to form metal into shape,' 'to fabricate')—the *crimen falsi* of Roman law, in

which it was punished with banishment or death, according to the enormity of the particular offence and the rank of the offender—is 'the making of a false document in order that it may be used as genuine;' and, in certain specified cases, 'the counterfeiting of a seal or die.'

The essential elements in the crime of forgery are (1) that there should be in the offender an intention to deceive, and (2) that the fabrication or alteration should be sufficiently skilful to render possible the deception of a person using ordinary observation. It is not necessary that the fraudulent imitation should be exact. The fraudulent application of a real signature to a false document, and of a false signature to a real one, are both forgeries.

The Forgery Act, 1913, now consolidates, simplifies, and amends, so far as England is concerned, the law relating to forgery and kindred offences. A document is 'false,' within the meaning of the act, if the whole or any material part of it purports to be made by or on behalf of a person who did not make it or authorise its making; or if, though made by or on behalf of such person, the time or place of making, where either is material, or, in the case of a document identified by number or mark, the number or any distinguishing mark is falsely stated. In particular, a document is 'false' (a) if any material alteration, whether by addition, insertion, obliteration, erasure, removal, or otherwise has been made in it; (b) if the whole or some material part of it purports to be made by or on behalf of a fictitious or deceased person; (c) if, though made in the name of an existing person, it is so made with the intention that it should pass as having been made by some other person, real or fictitious. For the purpose of the act (a) it is immaterial in what language a document is expressed, or in what place, within or without the king's dominions, it is to take effect; (b) the forgery may be complete even if the document, when forged, is incomplete, or is not or does not purport to be binding in law; (c) the crossing of any negotiable instrument is a material part of such instrument.

By the common law of England forgery was a mere misdemeanour, and punishable as such by fine, imprisonment, and the pillory; but capital punishment was the usual penalty (see, e.g., the cases of Dr Dodd in 1777 and Fauntleroy in 1824) for the more serious class of offences under this head. Capital punishment in cases of forgery was, however, restricted by acts passed between 1830 and 1832, and abolished in 1837 and 1861. Under the consolidating act of 1913 the punishment varies from penal servitude for life to not more than two years' imprisonment, with or without hard labour. A person injured by a forgery, whether by being deprived of a right, or by parting with property on the strength of it, is entitled to recover damages or the property parted with. People who pay on a forged document cannot, apart from statutory authority (see articles BANKING, BILL OF EXCHANGE), charge the person on whose account the payment is made with the amount paid. Their only remedy is against the recipient. The Forged Transfer Acts, 1891 and 1892, permit the making of compensation (by payments in cash instead of the issue of stock, &c.) for loss sustained through forged transfers of shares, stock, or securities.

Comparison of handwriting is primary evidence of forgery. The knowledge requisite for this purpose may have been acquired by the witness (i.) having seen the party write; (ii.) having received communications from him in the course of business; (iii.) being an expert in the comparison of handwriting, and having had the opportunity of comparing genuine specimens of the party's handwriting with the writing in dispute. The Forgery Act, 1913, does not apply to Scotland. Under Scots

law forgery is a crime at common law, and punishable as such.

See also the articles COINING, FRAUD, and TRADE-MARKS.

In the United States, also, falsification of writing is not necessarily forgery in a legal sense; the writing of letters and signing them with the name of another, however injurious to the feelings and interests of that other, is not forgery in law unless pecuniary rights, obligations, or engagements are intended to be directly affected by the false writing. The definition in Bishop's *Criminal Law* is: 'Forgery is the false making or materially altering, with intent to defraud, of any writing which, if genuine, might apparently be of legal efficacy in the foundation of a legal liability.'

LITERARY FORGERIES are to be distinguished from all use of pseudonyms, devised to conceal the identity of a writer; and from all writings in imitation of some author's style, and temporarily fathered upon him for mere literary purpose; as well as from so-called *pious* frauds, by which writings honestly intended for edification are connected with some more or less ancient name that commands respect. Such compositions as are deliberate attempts to pass for what they are not are literary forgeries, and are as unpardonable as forgeries of the signature of a London banker. The fictitious account of Formosa, with an alphabet and specimens of a language, published by George Psalmanazar in 1704, was such an imposture as could not long escape discovery. The most famous of such literary forgeries in English literature are connected with the name of Shakespeare—himself but a stalking-horse for another, according to thousands of half-educated people whom no evidence could satisfy. The famous Ireland forgeries began with an autograph of Shakespeare, fabricated by Samuel W. H. Ireland, to gratify his father, but soon grew into a heap of papers, and an entire play, entitled *Vortigern*, which was quickly damned at Drury Lane. The criticisms of Malone, and the alarm of young Ireland's father, necessitated a confession, published in 1796. Twenty years before, Chatterton's Rowley poems had opened up a bitter controversy about their authenticity, from which the boy-poet escaped by untimely suicide; and the Ossianic poems produced by MacPherson (1762-63) have been rank forgeries to a chain of scholars from Dr Johnson to J. F. Campbell, although as vigorously defended by many enthusiastic writers. The famous Perkins Folio of Shakespeare, said by J. P. Collier in 1852 to have been discovered, with an extensive series of contemporary marginal annotations, created a great commotion among Shakespeare scholars, but was at length unanimously condemned, and its annotations proved to be recent fabrications. In 1852 was published by Mr Moxon a series of letters by Shelley, which were discovered a few weeks later to be impudent forgeries, and were at once suppressed by the publisher. It was discovered that there was a brisk trade in the manufacture of letters, autographs, and marginal annotations upon books by Shelley, Byron, and others, and that many of these showed not only great technical skill in imitation, but no mean literary ability in their composition. It would be well for purchasers of letters and autographs of famous persons to make sure of their history, as there is still too good reason to believe that the supply of these is adapted to correspond with the demand. The most remarkable of all the dupes of literary forgers was Michel Chasles (q.v.), upon whom had been passed as many as 27,000 'autographs,' including those of Pascal, Shakespeare, Dante, and even Julius Cæsar. The fragment of a Moabite Deuteronomy, inscribed on fifteen pieces of sheepskin, brought to London in

1883 by Shapira, was a really skilful imitation, but failed to deceive Dr Ginsburg and Clermont-Ganneau. See books by E. K. Chambers (1891) and J. A. Farrer (1907).

Forget-me-not (the name is accounted for by various legends) is *Myosotis palustris*; but the term

Wood Forget-me-not
(*Myosotis silvatica*):
a, a flower.

has spread to the larger-flowered species, and indeed to all the members of the genus—practically superseding the more prosaic title of Scorpion-grass, derived from the inflorescence so characteristic of the Boraginaceæ, and also that of Mouse-ear, from the hairy leaves. *M. silvatica*, the wood forget-me-not, the Alpine *M. alpestris*, and among exotic species *M. azorica*, are especially worthy of cultivation. *M. versicolor*, a common weed, is remarkable for the change of colour in its

flowers, which not only show the change from red to blue in opening so common in the order, but begin with a distinct yellow. By the doctrine of Signatures (q.v.), *Myosotis* was like a scorpion's tail, and therefore good for scorpion bites. The newer name came from Germany, and was so little known in England in 1800 that to 'Hope's gentle gem, the sweet forget-me-not' Coleridge appended a note explaining what plant he meant.

Forisfiliation (lit., 'the putting forth from or beyond the family') is the separation of a child from the family of his father, as by marriage, or by receiving from his father a separate stock, the profits of which are enjoyed by himself, or by renouncing *Legitim* (q.v.).

Fork. See CUTLERY.

Forlì, capital of the province of the same name in Italy, situated at the foot of the Apennines, in a pleasant and fertile plain, 40 miles SE. of Bologna by rail, is a well-built and handsome city. Of the churches the cathedral, S. Girolamo, and S. Mercuriale are the most notable. In these and in the city gallery are some of the best pictures of Cignani, Guido, Melozzo, Guercino, and others. The citadel, founded in 1361, is now used as a prison. There are manufactures of silk, shoes, hats, and cloth. Forlì (the ancient *Forum Livii*) is said to have been founded by Livius Salinator, after his victory over Hasdrubal, on the Metaurus, 207 B.C. In the middle ages it formed a republic, and during the subsequent struggles of the Guelphs and Ghibellines frequently changed its rulers. In 1860 Forlì, which had been incorporated in the States of the Church since the time of Pope Julius II., became Italian. Pop. 52,000.

Forlorn-hope, the body of men selected to effect a lodgment on a breach, or to lead in scaling the wall of a fortress. The word is from the Dutch *de verloren hoop* (*hoop* pron. as English *hope*), 'the lost band or troop'; Fr. *enfants perdus*.

Form, in music, is the scheme of symmetry underlying the construction of a composition. Many pieces are built upon the plan of a Song (q.v.); the first movement of a Sonata (q.v.) or Symphony (q.v.) shows another fundamental form; and a third is the Rondo (q.v.). The Symphony as a whole developed out of the Suite, and has in turn given rise to the fiercer 'symphonic piece' or 'symphonic poem.' For form in philosophy, see ARISTOTLE.

Formalin, a powerful antiseptic and disinfectant, is a watery solution of formaldehyde (formic aldehyde; see ALDEHYDE). It is largely used on the Continent for preserving milk, and is not so innocuous as is sometimes represented.

Forma Pauperis. See IN FORMA PAUPERIS.

Formation has by English geologists been generally applied to a group of strata united by some character which they have in common, whether of age, origin, or composition, as the *Carboniferous Limestone formation*, which, together with the formations of the *Millstone Grit* and the *Coal-measures*, constitutes the Carboniferous System. The term is therefore of subordinate importance to *system*. Foreign geologists seldom use formation in this sense. With them the word is descriptive of the materials composing strata, as *chalk formation*, meaning thereby not the Cretaceous System, but beds composed of chalk; so *carboniferous formation* is a group of beds containing coal. To bring our nomenclature into uniformity with that of foreign geologists some purists propose dropping the term formation out of our systems of rock classification. But to do that would require despotic authority, and the term will probably survive in spite of its supposed inconvenience.

Formes, KARL, bass singer, was born in 1810 at Mulheim, on the Rhine, and was for some years a verger before he made his début on the stage at Cologne, in 1842, as Sarastro in the *Zauberflöte*. He was engaged for a time in Vienna, and sang in Italian opera at Covent Garden until 1857, when he visited America, and entered on a comparatively wandering life, in spite of the possession of a voice that for volume, compass, and quality was one of the most magnificent ever heard. He died at San Francisco, 15th December 1889.—His brother, THEODOR, born in 1826, appeared first at Ofen in 1846, and was long one of the most noted tenor singers in Germany. He died in 1874.

Formia, formerly Mola di Gaeta, a seaport of Italy, on the Gulf of Gaeta, with 12,000 inhabitants. The ancient *Formice*, it became a Roman town in 338 B.C., and was celebrated for its wine. Here are the ruins of Cicero's villa, *Formianum*.

Formic Acid, CH_2O_2 or HCOOH , derives its name from the circumstance of its having been first obtained from the red ant (*Formica rufa*). It occurs in ants, in the stings of bees, wasps, and nettles, in fir needles, and in various animal secretions. It may be obtained from any of these by distillation with water. Anhydrous formic acid is a mobile liquid of extremely penetrating odour, crystallising at 35° F., and boiling at 214° F., miscible in all proportions with water and alcohol. It produces a painful blister if dropped on the skin. The aqueous acid is prepared in the following manner: Half a pound of oxalic acid is mixed with one pound of glycerine, and the mixture heated in a retort to 275° F.; a little dilute formic acid distils; another quantity of oxalic acid is added, and the mixture again heated, and so on indefinitely, the glycerine remaining unchanged at the end of the operation. The decomposition is as follows:

Acid containing 56 per cent. of the pure substance

is obtained in this way. The anhydrous acid is procured by preparing the lead salt, and decomposing this with sulphuretted hydrogen. It may be formed synthetically in various ways: (1) By direct combination of carbonic oxide, CO, and caustic potash, KOH, forming KCO_3H , potassium formate; (2) by boiling aqueous prussic acid; (3) by heating chloroform with caustic potash. Formic acid and all its salts (called formates or formiates) are strong reducing agents, and precipitate metal from solutions of gold, silver, or mercury salts. Formic acid is obtained in small quantities by the oxidation of a great number of organic substances. Formates of silver and lead are sparingly soluble; all the others are freely so. By heat they are converted into oxalates yielding pure hydrogen.

Formosa, called by the Chinese and Japanese *Taiwan*, an island lying off the Chinese province of Fû-chien, from which it is separated by a strait from 90 to 220 miles wide. Formosa, which was ceded by China to Japan in 1895, is crossed by the meridian 121° E. and the Tropic of Cancer, and has a maximum length of 235 miles, whilst its breadth varies from 70 to 90 miles. Area, 14,000 sq. m. Forming one link in the volcanic chain that extends from the Aleutian Islands southwards to New Guinea, it constitutes the eastern escarpment of what was once the great Malayo-Chinese continent, and is connected by a submarine plateau with the Chinese mainland. The backbone of the island, extending north and south, is formed of a range of densely-wooded mountains, of which the highest peak, Mount Morrison (renamed Niitake-yama by the Japanese), is 14,270 feet high; Mount Sylvia, the second, is 12,480. Eastward of this range lies a narrow strip of mountainous country, presenting to the Pacific a precipitous cliff-wall with in many places a sheer descent of from 5000 to 7000 feet, whilst a very short distance farther east the floor of the ocean sinks to a great depth at an extremely steep gradient. The western side of the range consists of a single broad alluvial plain, stretching from north to south of the island, seamed by innumerable water channels, and terminating at the coast-line in mud flats and sand-banks. Yet on this side of the island the land is rapidly encroaching upon the sea, as the consequence of the gradual elevation of the western seaboard and the deposition in and around the embouchures of the rivers of the large amount of sediment brought down by them from the mountains. This latter process is primarily due to the heavy rainfall of the northern, central, and eastern portions of the island, where the rain-clouds of the north-east monsoon, after crossing the warm Kiosiu or Japanese Gulf Stream, on coming in contact with the mountain barrier of the island become chilled and discharge their contents in rains of excessive violence. Apart from this heavy rainfall, the climate is not exceptional, the insular position ensuring a modification of the heat by sea-breezes. The mean of summer is 80° to 90° F.; of winter, 50° to 60° . Violent typhoons are very common at certain seasons.

The island is famous for the rich luxuriance of its vegetation, many of our hothouse plants growing wild on the mountain slopes and in the valleys, and there is a profusion of ferns, tree-ferns, camphor and teak trees, pines, firs, wild fig-trees, liquidambars, bananas, bamboos, and palms. 'Rice paper' is prepared from the pith of a tree peculiar to Formosa. Of animal life it is noticeable that there are a great number of species of birds peculiar to the island, that insects are scarce, and that noxious wild animals are few, but that fish are plentiful in the waters round the coast. The principal products of commer-

cial importance are tea, sugar, coal, turmeric, rice, sweet potatoes, ground-nuts, bamboos and rattan, grasses, tobacco, timber, the fruit lung-ngan, sesame-seed, and above all camphor, the specialty of the island. Coal is worked, and a little petroleum exported; gold is found in the river gravel, and is collected; sulphur is abundant, especially in the north; and iron and silver exist. The principal exports are camphor and tea; the imports, opium, cottons, and woollens. The Japanese sought to prohibit the importation of opium, but have been compelled to make the trade in it, like that of camphor and salt, a government monopoly. A very large proportion of the shipping trade is carried on by means of native junks, which ply to and from the mainland; the remainder mostly in British bottoms. The principal ports are Tamsui, Kilung, Takow, Taiwan, and Anping. Kilung has become an important bunkering port. Most of the trade is with Japan—China, Britain, and the United States sharing the rest. Taiwan was the seat of government till 1887, when it was transferred to Tai-pei or Taihoku (pop. 163,000). The Pescadores, or Hokoto Islands, also ceded to Japan in 1895, are a group of basaltic islands 20 to 25 miles west of Formosa, with an area of 50 sq. m. and a population believed to amount to some 55,000.

The inhabitants of Formosa, numbering in 1920 3,654,398 in all, consist of Chinese settlers, about 153,000 Japanese, and 104,000 aborigines, who seem to consist of several different tribes, mainly of Malayan and Negrito descent. Three divisions are recognised: Pepohwan, civilised and sinicised agriculturists; Sekhwan, other settled tribes; and Chihhwan, the untamed savages of the mountains, who waged fierce and unceasing warfare against the Chinese immigrants. Of the natives, whose language is Malayan, not very much is known. There seems to be evidence of matriarchate. Priestesses are prominent in their religion, and seek to influence the spirits by slashing at them with long knives in their wild dances. Head-hunting is going out of fashion. The civil government of Japan has entirely subdued the turbulent element, and made well-nigh incredible progress in equipping an administration of more than European modernity. Hygienic works, including sewage disposal, water-supply, and hospitals, have been carried out, and an efficient educational system established, with elementary and normal schools. Roads and railways have been made; the post and telegraph offices are complete. The island was known to the Chinese before the Christian era, but does not seem to have seriously attracted their attention until the year 605 or 606 A.D. In the 14th century they established several colonies in Formosa, which, however, were withdrawn in the middle of the 17th century. Although Portuguese and Spanish navigators began to visit the island a century earlier, the first European people to establish themselves on it were the Dutch, who in 1624 built Fort Zelandia, near the modern Taiwan. They were, however, expelled in 1661 by a Chinese adventurer, Koxinga, who retained possession of the island for twenty-two years. Some years later a regular Chinese colonisation of the western half of the island was carried through, the colonists coming principally from Fû-chien and Kwang-tung. Subsequently the island became notorious for the piracy of its inhabitants and the ill-treatment they inflicted upon navigators who chanced to be wrecked on their coasts. Accordingly in 1874 the Japanese invaded Formosa; but on the Chinese undertaking to check the evils complained of they withdrew. Ten years later the French, during their contest with China in Tongking, held for a time the coal districts of Kilung. The occupation by the

Japanese troops did not take place without opposition from the natives and Chinese 'Black flags.' But the Japanese were practically in full possession of the island before the end of 1895, and set themselves at once to the work of reorganisation.

See, besides the older authorities, Guillemard, *Cruise of the 'Marchesa'* (1886); Terrien de Lacouperie, in *Jour. Roy. Asiatic Soc.* for 1887; Girard de Rialle, in *Revue d'Anthropologie* for 1885; Imbault-Huard, *L'Île Formosa* (1893); W. Campbell, *Formosa under the Dutch* (1903); J. W. Davidson, *The Island of Formosa Past and Present* (1903); Y. Takekoshi, *Japanese Rule in Formosa* (1907); Mis McGovern, *Among the Headhunters of Formosa* (1922); Owen Rutter, *Through Formosa* (1923); B. Hayata, *Icones Plantarum Formosarum*. The *Description of Formosa* (1704) by Psalmanazar (q.v.) was a tissue of inventions.

Formosa, a territory in the extreme north of Argentine Republic, formed in 1884, and bounded on three sides by the rivers Pilcomayo, Paraguay, and Bermejo. Estimated area, 41,400 sq. miles; pop. 20,000. The country is generally a vast plain, gently sinking to the south-east, covered with forests, and in large sections liable to frequent inundations, the summer rains lasting from October to May. The capital is Formosa, on the Paraguay, about 100 miles NNE. of Corrientes.

Forms of Address. See ADDRESS.

Formulae. See CHEMISTRY.

Forres, a royal burgh of Elginshire, 5 miles S. of Findhorn village on the Moray Firth, and 25 ENE. of Inverness, with which and Nairn and Fortrose it returned a member to parliament until 1918. On its Castle Hill, a royal residence from 1189 to 1371, stands an obelisk (1857), 65 feet high, to the Crimean hero, Dr Thomson of Cromarty; whilst on the wooded Cluny Hill are a hydropathic establishment, and the Nelson tower (1806), 70 feet high. Sueno's Stone is a remarkable sculptured monolith, ascribed by Skene to the year 900; the Witch's Stone recalls Forres's old reputation for witchcraft, not in Macbeth's time alone. Public buildings are the town-house, Falconer museum, mechanics' institute, and Anderson's Institution. Pop. 4000.

Forrest, EDWIN, actor, was born in Philadelphia, 9th March 1806, his father being of Scotch descent, his mother a German, and made his first regular appearance on the stage there in 1820, as Douglas in Home's tragedy. At the age of twenty he appeared as Othello at the old Bowery Theatre in New York, where his immediate success was the foundation of a popularity that survived for many years. He played in London with great success in 1836-37, but at his appearance in 1845 his Macbeth was hissed by the audience; and an unworthy and spiteful resentment that prompted him, a few weeks later, to stand up in a private box in the Edinburgh Theatre and hiss Macready, utterly destroyed his reputation in England and Scotland. A more serious result of his jealous action was the Astor Place riot in New York in 1849, which ensued on the hissing of Macready's Macbeth by Forrest's sympathisers, and which ended in the death of twenty-two men. These events, and the public scandal attendant on a suit for divorce brought by his wife, lessened his fame and embittered his temper. He retired from the stage between 1853 and 1860, when he returned to fill at Niblo's Garden, New York, the most successful engagement of his life. Later tours proved failures, and, after a long struggle against weakness and disease, he made his last appearance as an actor in the part of Richelieu, at the Boston Globe Theatre in 1871. Even then a craving for the old-time applause led him to give readings from Shakespeare in several large towns; but these, too, proved unsuccessful,

205

and he retired to his native city, where he died of paralysis, 12th December 1872. Forrest has been not unjustly called an essentially melodramatic actor; his robust physique and powerful voice made the assumption of sentimental parts almost impossible. But his powers as a tragedian were of a very high order; his Lear, Othello, Coriolanus, and several other parts were justly ranked in their own day as memorable performances. With him the line of great American actors begins. See lives by Alger (1877), Barrett (1881), and Harrison (1889).

Forrest, BARON (SIR JOHN FORREST; 1847-1918), Australian explorer and politician, was born at Bunbury, in Western Australia, and from 1864 onwards was connected with the survey department of the colony. In 1869 he commanded an expedition in search of Leichhardt; in 1870 he headed an exploring expedition from Perth to Adelaide; in 1874, with his brother Alexander (born 1849), one from Champion Bay through the heart of Australia to the Adelaide-Port Darwin telegraph line. He was first premier and treasurer of Western Australia under responsible government (1890-1901); and joining the Federal Cabinet in 1901, he held several offices under Sir E. Barton and Mr Deakin (1901-4), and was treasurer in Mr Deakin's two later administrations (1905-8 and 1909-10), Mr Cook's (1913-14), and Mr Hughes's (1917-18). He was made a peer of the United Kingdom in 1918. Among his publications are *Explorations in Australia* (1876) and *Notes on Western Australia* (1884-87).—His brother ALEXANDER, besides taking part in John's journeys, in 1879 started, along with Hill, to explore the north-western parts of the Australian continent; discovered the fertile region now called Kimberley District; and ascended the river Fitzroy for a distance of about 250 miles. This journey was described in *Journal of an Expedition from the De Grey to Port Darwin* (1880).

Forrest, NATHAN BEDFORD (1821-77), a distinguished Confederate cavalry commander during the Civil War, was born at Chapel Hill, Tennessee, and was at first a slave-trader.

Forst, an industrial town of Prussia, 80 miles S.E. of Berlin by rail, has a population of about 32,000, mostly engaged in manufacturing buckskins, in cloth manufactories, and in tanneries. Forst has also a trade in cattle.

Förster, FRIEDRICH CHRISTOPH, poet and historian, born near Kamburg, in Saxe-Meiningen, on 24th September 1791, devoted himself at first to the study of archaeology and the history of art, but on the outbreak of the war of liberation joined the Lützow sharpshooters along with young Theodor Körner, and, like him, wrote fiery war-songs, stirring up his countrymen against the French. After his return to Berlin he taught for a while in the school of artillery and engineering, but was dismissed for writing a work criticising the Prussian constitution. In 1829, however, he was appointed a custodian of the Royal Art Museum at Berlin, where he died on 8th November 1868. He wrote several popular historical works, dealing chiefly with the war of liberation and the history of Prussia, including a collection of biographical sketches entitled *Preussens Helden im Krieg und Frieden*; and, besides these, three works on Wallenstein; a *History of Frederick William I.* (3 vols. 1835); *Urkundenbuch* (new ed. 2 vols. 1839); and *Die Hofe und Kabinette Europas im 18. Jahrhundert* (3 vols. 1836-39). His *Gedichte* appeared in 2 vols. 1838.

His brother ERNST, painter and writer, was born 8th April 1800. His passion for art was first awakened by Cornelius, under whose direction he executed various fresco pieces in Bonn and

Munich, from 1823 to 1825. An expedition to Italy for the purpose of making drawings from the old masters bore fruit in *Contributions to the History of Modern Art* (1836). From this time he abandoned painting and devoted himself almost exclusively to investigations bearing upon the history of art, his principal books being *Letters on Painting* (1838); *History of German Art* (5 vols. 1851-60); *Monuments of German Architecture, Sculpture, and Painting* (12 vols. 1853-69); *Introduction to the History of Art* (1862); biographies of Fra Angelico (1859), J. G. Muller (1851), Raphael (1867-68), and Cornelius (1874), and a translation, in conjunction with Schorn, of Vasari's *Lives of the Painters*. At the time of his death, on 29th April 1885 at Munich, Forster left two large works unfinished, a *History of Italian Art* (5 vols. 1869-78), and *Monuments of Italian Painting* (4 vols. 1870-82). He also edited the posthumous works of his father-in-law, Jean Paul (1836-38), and wrote several biographical works relating to the great humorist, the chief being the last five volumes of *Wahrheit aus Jean Paul's Leben* (1827-33).

Forster, JOHANN REINHOLD, a German traveller and naturalist, was born in Dirschau, in Prussia, on 22d October 1729. He was educated at Halle and Danzig for the clerical profession, but his favourite studies were languages, botany, and zoology. Repairing to England in 1766, he acted for a few years as a teacher at Warrington in Lancashire, until he was appointed to accompany Cook as naturalist during his second voyage in 1772. On Forster's return his son published an account of the journey from Forster's own note-books, whilst Forster himself wrote *Observations made during a Voyage round the World* (1778), chiefly on physical geography and natural history. Two years afterwards he received the appointment of professor of Natural History at Halle, where he died on 9th December 1798. He wrote also a work on *Mineralogy* (1768), one on the *Byssus of the Ancients* (1770), *Flora America Septentrionalis* (1771), *Zoologia Rarioris Specielegium* (1781), an *Account of the South Sea Plants* (1776), and *Geschichte der Entdeckungen und Schiffahrten im Norden* (1784).—His eldest son, JOHANN GEORG ADAM, was born near Danzig, on 26th November 1754. When only seventeen years of age, he accompanied his father in Captain Cook's second voyage, and published, with the assistance of his father, an account of the expedition. After living as professor of Natural History at Cassel and at Wilna, he became librarian to the Elector of Mainz in 1788. Whilst he was on a visit at Paris in 1792, whither he had been sent to request the incorporation of Mainz with the French republic, the Prussians retook Mainz, and Forster lost all his property, including his books and manuscripts. He died at Paris, 12th January 1794. His writings, especially his *Ansichten vom Niederrhein* (1791-94) and his *Beschreibung einer Reise um die Welt* (1784), take a high rank amongst German works descriptive of nature. His Letters were published by his widow in 1829; and a complete edition of his works appeared in 9 vols. in 1843.

Forster, JOHN, an English political and historical writer, was born at Newcastle, 2d April 1812. He was educated for the bar, but early devoted himself to periodical writing. His political articles in the London *Examiner*, for which he commenced writing in 1833, attracted more attention than is usually bestowed on newspaper leaders, owing to their vigour and point, coupled with the love of truth, consistency, and outspoken honesty they displayed. Forster edited the *Foreign Quarterly Review* for some time; then for nearly a year, as Dickens's successor, the *Daily News*, and from 1847 to 1856 the *Examiner*. He was the author

of many admirable biographical and historical essays, as the two volumes of *Edinburgh and Quarterly* articles reprinted in 1858, and an admirable series dealing with the times and statesmen of the English Commonwealth, under the titles *History of the Grand Remonstrance* (1860); *Arrest of the Five Members* (1860); *Sir John Eliot, a Biography* (1864); and *Lives of the Statesmen of the Commonwealth* (1840). His literary memoirs are *The Life and Times of Oliver Goldsmith* (1848; 2d and improved ed. 1854), accounted one of the best biographies in English literature; *Walter Savage Landor* (2 vols. 1868); *The Life of Charles Dickens* (3 vols. 1871-74); and the first volume of a *Life of Swift* (1875). His life of Dickens was assailed as having exposed with too great frankness the failings of his hero; a more valid objection is that in the method of treatment adopted the biographer is almost as prominent as his subject. Forster's style is clear and forcible. He himself was an indefatigable student and a constant and devoted friend. He was appointed secretary to the Commissioners in Lunacy in 1855, and a Commissioner in 1861. He died 1st February 1876. See Renton, *Forster and his Friendships* (1912).

Forster, WILLIAM EDWARD, statesman, was born at Bradpole, Dorsetshire, July 11, 1819, the son of an esteemed minister of the Society of Friends, who died while on an anti-slavery mission in Tennessee, in 1854. Educated at the Friends' School at Tottenham, he first contemplated going to the bar, but abandoned this intention for commerce, and accepted an appointment in a worsted manufactory near Bradford. He early took an interest in philanthropic and political questions, and during the terrible Irish famine of 1845 visited the distressed districts as almoner of a relief fund raised by his co-religionists. In 1850 he married Jane, eldest daughter of Dr Arnold of Rugby, and sister of Matthew Arnold. Forster unsuccessfully contested Leeds in the Liberal interest in 1859, but two years later was returned for Bradford. After serving for thirteen months as Under-secretary for the Colonies (1865-66), he became in 1868 Vice-president of the Council on Education, and a privy-councillor. He accepted from Mr Gladstone a seat in the cabinet in 1870, and the same year introduced the greatest legislative measure associated with his name, the Elementary Education Bill (see EDUCATION). His conduct of the bill was marked by great ability, but it led him into strong conflict with the Nonconformist members and the Birmingham League, who objected to the 25th clause, which enabled school boards to pay the fees of indigent children at denominational schools out of the rates. In 1872 Forster introduced the Ballot Bill, which he piloted through the House of Commons with much skill. After the resignation of the Liberal ministry in 1874, he visited the United States. His father's memory was warmly cherished by the abolitionists, and Forster himself, who had always been a staunch supporter of the Union, and an uncompromising enemy to slavery, received an enthusiastic welcome. He had counted among his personal friends Emerson, Adams, and Sumner. On the retirement of Mr Gladstone from the leadership of the Liberal party in January 1875, Forster and Lord Hartington were named for the post, but the former wrote withdrawing from candidature, on the ground that he could not hope to unite the various sections of the party. In the ensuing November he was elected Lord Rector of Aberdeen University.

In the Gladstone administration of 1880 Forster accepted the office of Chief-secretary for Ireland, at that time the most onerous post in the government. He had not coveted the appointment, but assumed it patriotically, in the hope of being able

to grapple with the Irish problem. An agrarian and political agitation was then disturbing a large portion of Ireland. Forster was attacked unceasingly in parliament by the Irish members, and his life was threatened by the 'Invincibles,' who afterwards assassinated his successor, Lord Frederick Cavendish, together with Mr Burke. More than one thousand evictions having taken place in Ireland during the first six months of 1880, Forster carried through the House of Commons the Compensation for Disturbance Bill, intended for the relief of deserving tenants evicted for non-payment of rents which they were unable to discharge. The measure was rejected by the Lords; and this proved a great blow to Forster, who believed that by its aid the government would have been able to cope with the rising influence of Mr Parnell, and with the growing agitation among the Irish peasantry. A land act was passed in 1881, but a coercion act was also necessary for the suppression of agrarian crime; and, when the Land League issued its 'No Rent' manifesto, Forster replied by a proclamation declaring the League illegal. Mr Parnell and several members of his party were arrested. Induced to adopt a change of policy by the continued disturbed condition of Ireland, in April 1882 a majority of the cabinet determined to release the 'suspects,' whereupon Forster and Lord Cowper (the Lord lieutenant) resigned. Considerable excitement arose over what was known as 'the Kilmainham Treaty,' and Forster was much applauded by the Conservatives for his policy in this matter, and for his attitude on the Irish question generally. Forster subsequently condemned the government for their action in Bechuanaland and also in the Sudan; and he supported the unsuccessful vote of censure upon them after the death of General Gordon. He took a profound interest in Imperial Federation. He believed that 'a parliament in Dublin would be fraught with danger to both England and Ireland.' In November 1885 he was again returned for Bradford, but he died in London, 5th April 1886. In character Forster was loyal, honest, unselfish, and courageous. He was an effective parliamentary speaker, from his straightforwardness and earnestness of conviction, but he had none of the shining gifts of oratory. See Life by Sir Wemyss Reid (1888).

Forsyth, SIR THOMAS DOUGLAS, K.C.S.I. (1827-86), Indian civilian, born in Liverpool, entered the Company's service in 1848, and was employed in the administration of the Punjab until 1870, being created C.B. for his services during the mutiny. In 1870 he conducted a mission to Yarkand in Eastern Turkestan, and in 1874, having crossed the great ranges that separate Kashgar from India, he concluded a commercial treaty with the emir. The reports of these missions contain much valuable geographical information. On his return Forsyth was made a member of the Legislative Council of India; and in 1875 he succeeded, acting as envoy, in averting war with Burma. See his *Autobiography* (1888), and Henderson and Hume, *Lahore to Yarkand* (1873).

Fort, PAUL, born in 1872 at Reims, began in 1895 to publish the pieces afterwards collected in the many volumes entitled generally *Ballades* and *Ballades françaises*. His so-called 'poèmes en prose' are prose only to the eye.

Fortaleza, capital of Ceará (q.v.).

Fort Augustus, a village on the Caledonian Canal, at the head of Loch Ness, 33 miles SW. of Inverness. A barrack built here in 1716 to awe the disaffected clans was enlarged in 1730 by General Wade, who named it Fort Augustus, out of compliment to William Augustus, Duke of Cumberland. The rebels captured and dismantled it in

1746, but it was soon restored, and garrisoned down to the Crimean war. In 1857 it was sold to Lord Lovat, whose son nineteen years afterwards presented it to the Benedictines (q.v.); and by them during 1876-82 it was converted into a stately abbey, college, and hospice.

Fort de France, capital of Martinique, in the French West Indies, lies on the west coast, and has an excellent harbour; pop. 27,000.

Fort Dodge, on the Des Moines River in Iowa, U.S., at the intersection of four railways, has some manufactures, and is near a vast coalfield; pop. 20,000.

Fortescue, SIR JOHN (1394?-1480?), educated at Exeter College, and called to the bar at Lincoln's Inn, he was in 1441 made serjeant-at-law, and in the following year Lord Chief-justice of the Court of King's Bench. In the struggle between the Houses of York and Lancaster he steadily adhered to the latter, and was attainted by the parliament under Edward IV. He accompanied Margaret of Anjou and her young son, Prince Edward, on their flight into Scotland, and is there supposed to have been appointed Lord Chancellor by Henry VI. In 1463 he embarked with the queen and her son for Holland. During his exile he wrote his celebrated work, *De Laudibus Legum Angliæ*, for the instruction of Prince Edward, who was his pupil. But on the final defeat of the Lancastrian party at the battle of Tewkesbury, 1471, where he is said to have been taken prisoner, Fortescue submitted to Edward IV. He died in about the ninetieth year of his age. The *De Laudibus Legum* was not printed until the reign of Henry VIII.; another valuable work by Fortescue is *The Governance of England*; otherwise called *The Difference between an Absolute and Limited Monarchy*, written in English (1714; new ed. by Plummer: Clarendon Press, 1885). His collected works were printed for private circulation by Lord Clermont in 1869.

Forteviot, the ancient capital of the Picts (q.v.). Its site is about 7 miles SW. of Perth.

Fort Garry. See WINNIPEG.

Fort George, a fortress 12 miles NE. of Inverness, on a low sandy projection into the Moray Firth, here only 1 mile broad. It was built in 1748, at a cost of £160,000, to keep the Highland clans in subjection. It is the dépôt of the Seaforth Highlanders.

Forth, a river and firth of Scotland. The river is formed by two head-streams, Duchray Water and the Avonduh, which, rising on and not far from Ben Lomond, at altitudes of 3000 and 1900 feet, run 14 and 9 miles to a confluence near Aberfoyle, the Avonduh traversing Lochs Chon and Ard. From their confluence, 80 feet above sea-level, the Forth itself winds 39 miles to Stirling, then 12½ (the 'Links of Forth') to Alloa, the distances in a straight line being only 18½ and 5½ miles. It receives the Teith, Allan Water, and Devon, and traverses or divides Stirling, Perth, and Clackmannan shires.

The Firth of Forth extends 51 miles eastward from Alloa to the German Ocean, between the counties of Clackmannan and Fife on the north, and Stirlingshire and the Lothians on the south. It has a width of ¼ mile at Kincardine, 3 miles above Bo'ness, 1½ at Queensferry, 5 between Granton and Burntisland, 17 at Prestonpans, and 8½ at Elie. Its waters, 3 to 37 fathoms deep, encircle the islands of Inchkeith (fortified), Inchcolm (with a ruined abbey), Cramond, &c., whilst at the entrance are the Bass Rock (q.v.) and the May. On the two last and on Inchkeith are lighthouses. Rivers falling into it are the Carron, Avon, Almond, Water of Leith, Esk, and Leven.

White Fish are plentiful. In 1882-90 a great railway bridge was erected across the Firth at Queensferry (see BRIDGE), above which is St Margaret's Hope, one of the safest roadsteads in the kingdom. Rosyth, on this bay, is a great naval base. See H. M. Cadell, *The Story of the Forth* (1913).

Fortification has two distinct branches, called Field and Permanent fortification. It consists substantially of the art of so dealing with the soil, of so using natural features, and of so applying to one's purposes suitable materials of all kinds that the enemy's difficulty in reaching you is enhanced. You wish to hold a given stretch of ground with troops that are, necessarily or of design, weaker than those the enemy can, and is likely to, bring against that stretch. He hopes to reach you, and then to use his superior force upon you, by two means; by his fire he will try to beat down the defenders' fire, and through advance by favour of that beating down he means to reach you with superior numbers. Fortification is the antidote, for it aims at giving cover to the defenders, but not that only; it aims also at enabling them to use their weapons in the most effective manner from first to last. Therefore the military engineer plans so to deal with the soil, and with materials such as concrete, masonry, timber, and iron, that cover shall be of the best possible; and he does his best, also, by good siting of the works and by the provision of obstacles in the way of an advancing enemy, to keep him under fire to the utmost possible extent.

This applies, as a general statement of aim, both

come to be called *camouflage*—that is, clever disguising of objects.

The wars of this century have, chiefly owing to increase of power in firearms, brought about a steady development of fortification from the model shapes of earlier times to an astonishing irregularity of treatment. Every case has become a particular case, and it is hardly possible to lay down a type. The change is patent when one looks at figs. 1 and 2, a plan and sections of what may be reckoned a typical redoubt of the last decade of the 19th century. Such a work would be held a mere shell-trap now, capable of being wrecked by a modern enemy at short notice. The work we should now build in place of this would have hardly anything above ground, might have its subterranean parts as much as 30 feet deep, would have no guns in it, and would be surrounded by belt on belt of barbed wire.

This matter of obstacles is reckoned an important branch of fortification. As the aim in planning an obstacle is to keep an advancing enemy longer under fire, it is to be placed within effective range of one's small-arms, and is to be of such a kind that it does not itself afford any concealment. The wire entanglement, woven between strong posts, is, therefore, the best known, while in some cases *inundation* has proved first-rate. Obstacles obtained by digging are not liked, because they give cover, but a deep and wide excavation, such as a canal, is useful for stopping tanks. See ABATTIS.

The names of the various shapes of works of older types are all French. The redoubt in fig. 1 is a *blunted redan*, and would be a plain *redan* or *flèche* if the two faces were continued upwards to meet. The rear face is called the *gorge*, and was often a mere palisade or even left open. A *lunette* had two faces, two flanks, and a gorge, making a plan like the gable of a house seen in elevation. In fig. 1 the *bonnettes* on the forward angles were portions of the parapet higher than the rest; the *barbettes* were gun-platforms high enough to let the artillery fire over the parapet, this method affording a wider field of fire than was given by the *embrasures* to the guns on the flanks, but rendering the guns and their crews more vulnerable. The *traverses* were short masses of earth, perpendicular to the parapet on its inner side, placed at intervals

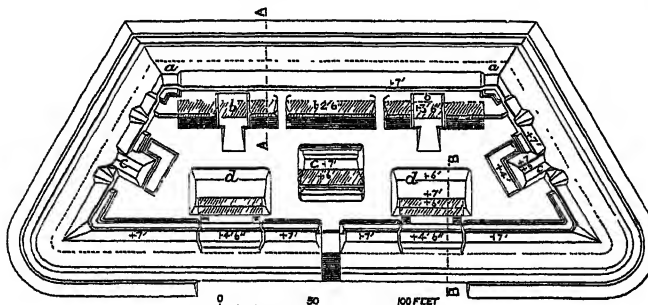

Fig. 1.—Plan of Field Redoubt:

aa, bonnettes; bb, barbets; cc, traverses; dd, parados. The diagonal shading indicates the position of casemates. NOTE.—In this and in figs. 2, 5, and 6 the reliefs are given in feet relatively to the plane of site (+ above, - below).

to Field and Permanent fortification, the former being the comparatively hasty work executed by the troops themselves during war or in face of threats, the latter the more elaborate constructions, using quantities of concrete and iron as well as earth, executed by governments in peace-time. Here it should also be said that during the Great War iron and concrete were pretty freely used in field entrenchments, but this only became possible owing to the stagnation along the fronts of the long period of 'trench warfare.' It should also be said that two developments in the war caused two corresponding additions to the art of fortification. One of the developments was the use in field warfare of very heavy artillery, firing shell of terrific explosive power, guns and shells being also in unheard-of numbers. The second was the perfecting of reconnaissance by aeroplane, enabling the gunners to have immediate and accurate information as to the correctness or incorrectness of their ranging. These two developments added greatly to the necessary depth for overhead cover that was to be safe, and also increased the value of what has

as shelter from enfilade fire—that is, fire arriving in the line of the parapet. The *parados* were banks of earth to guard against fire against men's backs, as *parapet* means the guard of the breast. The ditch was often broad and deep enough to be an obstacle, and was improved as such by a *palisade* in the bottom or by *frises* projecting from the *escarp* or *counterscarp*. These last are, respectively, the near and the far sides of the ditch.

The names of other elements of a complete field fortification are as follows: *command*, the height of the crest of parapet above ground; *crest*, highest point of parapet; *berm*, ground left between foot of parapet and ditch; *exterior*, *superior*, *interior slopes* of parapet—the first usually left at natural slope of earth, second nearly level, third steep at $\frac{1}{2}$ or $\frac{3}{4}$, so that the rifleman may stand close up to the crest, such slopes requiring revetments of brush-wood, timber, sods, bricks, or other material. The *banquette* is the broad step on which the soldier stands to fire; the *terreplein* is the interior level space of the work. Accessories are *tambours*, small stockades projecting from a face, to provide flank-

ing fire along the face; these were called *caponiers* when in a ditch, where they were roofed over. Such works, when standing quite detached, are *Blockhouses* (q.v.). None of these works, made of the dimensions and materials of last century, is allowable now against an enemy who has modern guns.

During the Great War it was found that in field fortification there must be no approach to putting many of one's eggs into one basket. There must be no crowding of one's men on the defensive; more than ever, in modern war 'death loves a crowd.' It was found that, until the moment of hand-to-hand fighting arrived, there must be nowhere a big human target for the enemy shells. The defender must contrive to do his work with machine-guns, which produce much fire in proportion to the number of men whom their manning exposes to the enemy. By careful siting and dis-

rear, and the best of them were so strong as to resist a direct hit of any but the very largest shells. They were small and difficult targets for the artillery, but the concussion of a hit was sometimes sufficient to kill all the occupants.

The preparation of houses, woods, quarries, existing hedges and ditches for defence is also included in field fortification. Houses or aggregations of houses may be of value for a moment at the first brush with the enemy, but when modern artillery opens on them their remaining strength resides in their cellars and in the cover sometimes afforded by heaps of ruins. Large woods are worth fortifying, for they afford concealment even from the enemy aircraft. When time is short, existing hedges, ditches, and banks may be of value if they are properly sited for your tactical purpose.

PERMANENT FORTIFICATION, for the protection of cities, harbours, tracts of country, bridges (see **BRIDGE-HEAD**), roads, &c., dates from the earliest ages. Its aim formerly was to keep out the enemy by passive resistance unaccompanied by counter-attacks, except in the form of sorties to destroy his siege-works and batteries. Since 1859, however, the same principle of detached works and free manœuvring ground between them for counter-attack which has been applied to field fortification has been adopted for permanent works. This is due to the vast improvements in artillery and small-arms, the former easily destroying the strongest works at long distances, and the latter, on the other hand, increasing the power of armies

in the open field. The change has been gradual but progressive. In Greek history we read of cities surrounded with walls of brick, stone, and rubble. Babylon had a wall of prodigious circuit—100 feet high, 32 feet thick, and surmounted by towers. Jerusalem, at the time of Vespasian's siege, had similar walls, with masonry of enormous solidity. But the square and round towers, which had formed sufficient flanking defence against arrows, and the walls which had resisted battering-rams,

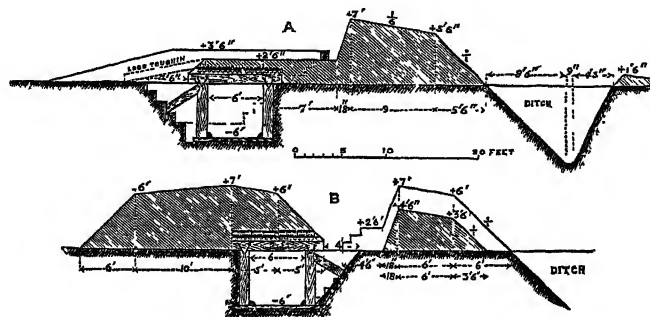

Fig. 2.

guising, he must contrive to hide as many as possible of these machine-gun nests from the foe, so that when the crisis of the attack is approaching there may still be enough weapons available for those critical minutes when the bayonet-fight is very near. The Germans even tried to make machine-gun emplacements shellproof, by constructing what our men called 'pill-boxes.' These were enormous masses of reinforced concrete, enclosing a small loopholed chamber with exit to the

were soon found to be useless against artillery, and other devices had to be resorted to.

Bastion System.—Early in the 15th century the

Italians commenced to flank their walls with small bastions. These are works of *lunette* shape (see above), having two faces, two flanks, and an open

gorge. A *bastion front* consists of a *face* and a *flank* of each of two adjoining bastions, joined by a *curtain* (see fig. 3). Those at Verona, built by Micheli in 1523, are usually looked upon as the oldest extant. Tartaglia and Albert Duier, painter and engineer; Marchi, an Italian, who died 1599; Errard Bois-le-Duc and De Ville, under Henry IV. and Louis XIII. of France; and the Count de Pagan, whose treatise appeared in 1645, did much towards laying the foundation of that science which Vauban subsequently brought almost to perfection. Born in 1633, this great engineer was equally distinguished in peace and in war. After having taught how fortresses could be rendered almost impregnable, he was led by the restless ambition of his master, Louis XIV., to demonstrate that the reduction of any work was a mere question of time and powder, so that even he himself could not construct a rampart that should withstand the fire brought against it by his system of attack. He constructed thirty-three new fortresses, improved above one hundred, and conducted personally more than fifty sieges. Coehoorn, director-general of the fortresses of the United Provinces, was the contemporary, rival, and opponent of Vauban; his masterpiece was Bergen-op-Zoom. Cormontaigne, Belidor, Bousmard, and Carnot may also be mentioned as conspicuous followers of Vauban's principal theories. Their works all begin by surrounding the place with a continuous polygon, on each side of which a bastion front, covered by outworks, is constructed.

The *enceinte*, or main body of the place, is traced as follows, if the polygon taken is an octagon. The *exterior side*, about 380 yards long, *ab* (fig. 3), is bisected in *c* by the perpendicular *cC*, which is made one-sixth of *ab*; *aC*, *bC* are joined and produced, and the faces of the bastions *ad*, *bg*, each equal to two-sevenths *ab*, are measured along them. Next, from *a* and *b* as centres, with radius *ag*, arcs are described cutting *aC*, *bC*, produced in *f* and *e*; *de*, *fg* form the flanks of bastions, and *ef* the curtain. The rampart is formed from the earth excavated from the ditch, and the parapet built on it. It will be seen from the plan that the faces and curtain provide fire over the country beyond the ditch, while the flanks are built for fire into the ditch under faces and curtain, where an enemy is not visible from the faces or curtain. The *capital* of the bastion is a line bisecting its salient or forward angle, and it is seen that in this direction the defender's fire is not good; consequently the besieger

is apt to advance his sap on that line, but is in his turn met by the engineer adding, in front of the curtain, a *ravelin* or *redan* (F in fig. 3). The *covered way*, G, 10 yards wide, is covered by the *glacis*, K, 8 or 10 feet high, and sloping gradually towards the country. Traverses in the covered way prevent its being enfiladed. The *tenaille*, C, is a low parapet sweeping the interior of the ravelin and the ditch; it also protects the scarp revetments of the bastions and curtain.

The *caponier*, D, forming a communication between the *tenaille* and the ravelin, consists of a passage between two low parapets, each with a *glacis* sloping towards the ditch, which is swept by their fire. At the re-entering angles of the covered way *places of arms*, I, are formed by setting off 30 yards along each counterscarp for the gorge, and making the faces enclose a salient angle of 100°. These, and the *salient place of arms*, H, are convenient for preparing sorties.

Vauban's second and third systems were methods of improving existing works of simpler design.

Coehoorn's system had counterguards in front of the bastions and parallel to them. The angle of his ravelin was always 70°, and his flanks were protected by curved shoulders called *orillons*.

Cormontaigne widened the gorge of his ravelin, thereby reducing the length of the bastion face exposed to breaching. He also revived the step-like formation of the covered way, originally seen in the system of the great German engineer Speckle (died 1589), which gives defenders a continued line of fire from each traverse along the covered way; and he placed redoubts in the re-entering places of arms.

Modifications led up to the so-called *modern French system*, without great changes. *Horn-works* and *Crown-works* (q.v.) were added in front of ravelins, *fausses brayes* or lower parapets outside the bastions, *cavaliers* (elevated retrenchments) within them. Improved breaching-power in cannon, making escarp masonry an easy prey, then necessitated *counterguards* and *couvre-faces* of masonry and earth.

The *tenaille* or star trace consists of alternate salient and re-entering angles, the latter being not less than 90°. Ravelins and other outworks are added as in the bastion trace. It was chiefly used by Montalembert (1714-1800), but has many defects—e.g. the salients are easily enfiladed; the interior space is confined; the defence of the main ditch from the ramparts is very imperfect; and if

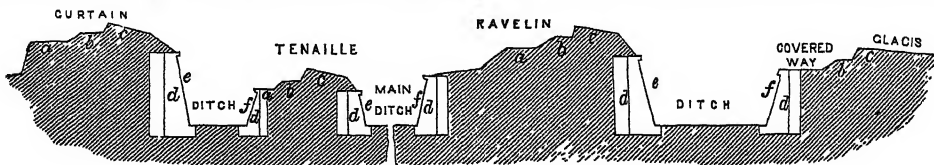

Fig. 4.—Vauban's First System (profile):

a, rampart; b, banquettes; c, parapet; d, revetment; e, escarp; f, counterscarp.

casemates are used at the re-entering angles to remedy this defect, they can be destroyed by the enemy's fire passing along the ditch.

The Polygonal System.—Early in the 19th century the German Engineers had recognised that the 'polygonal system' of fortification invented by Montalembert was better adapted to the increased range and accuracy of artillery fire. This system placed the parapets of the *enceinte* along the sides of the polygon, sometimes broken slightly outwards or inwards, and always flanked by strong casemated caponiers projecting from their centres. These caponiers mount thirty to forty guns in two or three tiers, firing through *masks* or *tunnels* in

many cases, and are themselves protected by counterguards and ravelins, besides being flanked from batteries in rear. Fig. 5, a half-front of the Antwerp *enceinte* (1859), as fortified by General Brialmont of the Belgian Engineers, is perhaps the best example of this system. Besides simplicity, each front has greater length (1200 yards as against 400), better bombproof cover, communications, retrenchments, and flank defence. It is more easily adapted to the site. Its ravelins are wider, but support one another less, and it is more vulnerable to attack by mining.

But the fortifications of Antwerp also illustrate another change in this science, by which advanced

works close to the enceinte were replaced by a chain of detached forts 3 to 5 miles from it. The value of a chain of redoubts was proved at Pultowa, Fontenoy, Torres Vedras, and Dresden. D'Arcon first, and Rogniat after him in 1816, both of the French Engineers, strongly advocated the 'camp-fortress,' as it is called by the Austrians, and it soon became the only recognised system of fortification. It was applied to Portsmouth, Plymouth, Paris, the Rhine fortresses, throughout the Franco-German frontier, and wherever modern defences became necessary.

The continuous *enceinte*, built at enormous cost, is now out of favour, any such being untenable against modern guns when once the outer forts are taken. These also in the Great War succumbed quickly under the blows of modern shells, and the defence of the place practically depended on the field army, using field fortification. It is not that the strength of permanent works is valueless, but

are of steel, and have hydraulic machinery for raising them when the gun is to fire. In the Great War no cupolas proved really shellproof, so great is the weight of the modern shell, so powerful the shattering energy of its explosive charge, and so accurate its flight. In the case of these permanent works, the enemy usually knows their plan from peace-time, and can find cupola and gun even if these are disguised, while the besieger's guns, installed by night and camouflaged, may take days for the besieged to discover, and can be shifted if threatened. As an example of war experience, the first-class forts of Douaumont and Vaux, of the fortress of Verdun, were disarmed by the French in 1915; when the Germans attacked next spring, the forts were manned only by a company each of infantry.

Coast fortifications used to be held as constituting a different problem, owing to the weight of ships' guns; but it has now been shown that in-

land warfare can be troubled with artillery just as heavy. Great closed works of permanent type are not needed; the batteries are hidden away carefully; anti-aircraft arrangements are perfected; the guns are put up on high ground if such is available. The enemy is kept at a distance by mines anchored in zones, searchlights help in preventing him sweeping the mines up by night, submarines and destroyers perpetually threaten his near approach. Very seldom have warships successfully attacked coast works of good quality of construction, of armament, and of garrison. In the Russo-Japanese war (1904-5), the Japanese only once fought Port Arthur from the sea, and with no success. In the Great War the Allied fleets never dared attack the German permanent fortifications of the North Sea coast, while they often bombarded with some effect the batteries the enemy built on the Belgian coast. At the Dardanelles in 1915 the Allied fleets destroyed with little trouble the old permanent batteries near the water-level, but were beaten by the big guns installed and concealed high up among the hills, running on rails

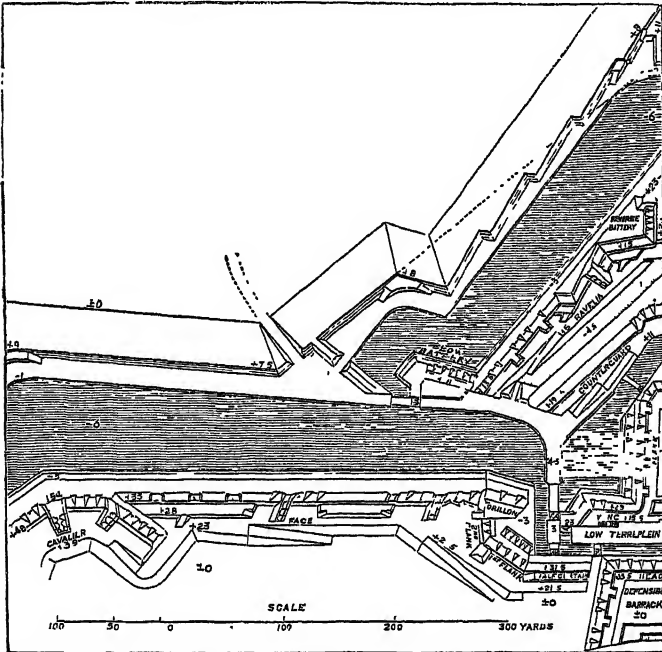

Fig. 5.—Half-front of the Enceinte of Antwerp.

they are to be looked upon as a help to a field army fighting a battle, rather than as a fortress meant to endure a siege with no help outside its own garrisons. When Napoleon was asked his view on fortifications, he replied, 'To gain time;' and it is the case that in the Great War time was gained by the Allies on some critical occasions. Another point is the assailant's necessity of calculating the *effort* required. Liège took thirteen days (5th to 17th August 1914) to capture, and its 25,000 garrison inflicted 42,000 casualties. Namur (19th to 25th August) cost 97,000 shells, which filled 25 long trains. Maubeuge (25th August to 8th September) held up 60,000 Germans, who were wanted on the Marne. Antwerp (28th September to 10th October) kept back 150,000 Germans, used 300,000 shells (100 trains), and 300 more trains for guns and stores.

The most powerful form of detached fort depended substantially on two things: (1) the depth of the underground shelters and the nature of their covering; (2) the resisting-power of the cupolas or overhead shields of the chief guns. These cupolas

and thus easily movable, and by the drifting mines floating down from the Sea of Marmora.

The cost of first-class works was coming, towards the end of the 19th century, to be judged prohibitive, and it was being said that the money would be better spent on perfecting the armament and equipment of the field troops. Consequently the patent increase in the destructive force of artillery was seldom adequately met by improvements in existing fortresses, while new ones of the first class meant the expenditure of many millions sterling.

The experience of the Great War has been such that, if permanent works are to be newly built, or old works brought really up to date, the constructions will be on no formal plan. Tunnelling on a great scale, along with roomy subterranean barracks, magazines, and food stores, will be a feature; every part will be knitted to every other part by deep-down passages carrying, in the chief of them at least, tram and railway lines. Infantry will man field entrenchments, prepared on the outbreak or the imminent threat of war, all communicating

with the deep chambers or tunnels by shafts or staircases. An immense number of machine-gun emplacements, rendered inconspicuous by siting and by disguises, will be dotted about everywhere, all having safe communications to the underground regions. There will be a complete network of duplicate and triplicate telephone-lines. The fortress will have an ample endowment of air service, with tunnelled hangars, shellproof. All the guns of the defence, except the lightest, will be on rails, with many alternative emplacements for the deception of the enemy's observers, and every gun will be capable of immediate withdrawal into perfect safety when threatened with being overpowered. The fortress will also have to contain, in conditions of safety from bombardment of every sort, a great outfit of military workshops. See MINES (MILITARY).

Clarke; *La Fortification permanente* (1908), by Deguise (Belgian); *Leitfaden für den Unterricht in der Befestigungslehre* (1914, German official book); *Textbook of Engineering* at Woolwich.

Fortiguerra, NICCOLO, an Italian poet, was born at Pistoia in 1674. He proceeded to Rome at an early period, and was speedily raised to the dignity of bishop and papal chamberlain by Clement XI. The greater part of his attention was given to letters; but he is now remembered only as the author of a satirical epic entitled *Il Ricciardetto* (1738), which is praised by his countrymen for its natural humour, grace of style, and elegance of versification. The best edition is one published at Milan in 3 vols. in 1813. Fortiguerra died at Rome, 17th February 1735.

Fort Madison, capital of Lee county, Iowa, on the Mississippi River, 19 miles SW. of Burlington by rail, with a state prison, and many manufactures; pop. 12,000.

Fortrose, a watering-place of Ross-shire, on the inner Moray Firth, 10 miles NNE. of Inverness, was one of the Inverness burghs; and its two portions, Chanonry and Rosemarkie, were constituted a royal burgh in 1590. The seat of a Columban monastery in the 6th century, of the bishopric of Ross from 1124, it retains the south aisle and chapter-house of a cathedral, demolished by Cromwell to furnish stones for his Inverness fort. Pop. 1000.

Fort Royal. See FORT DE FRANCE.

Fort St David, a ruined fortress on the coast of Madras Presidency, 100 miles S. of Madras, on the outskirts of Cuddalore. It became British in 1690, along with all the land round about to the distance of a 'randome shott,' and was an important place during the struggle with the French, forming the chief of the English settlements on the Coromandel coast from 1746 to 1752. It is of interest also from associations with Clive (q.v.), who became governor in 1756.

Fort St George. See MADRAS.

Fort Scott, in Kansas, on the Marmion River, 98 miles S. of Kansas city. A railway junction, it has foundries, machine-shops, flour and other mills, and trade in coal. Pop. 10,700.

Fort Smith, in Arkansas, stands on the south bank of the Arkansas River, and has a large trade and some miscellaneous manufactures; pop. 30,000.

Fort Sumter. See SUMTER.

Fortuna, called by the Greeks *Tychē*, was in classical mythology the goddess of Chance. According to Hesiod, she was a daughter of Oceanus; according to Pindar, a sister of the Parcae. She differed from Destiny or Fate in so far that she worked without law, giving or taking away at her own good pleasure, and dispensing joy or sorrow indifferently. She had temples at Smyrna, Corinth,

and Elis. In Italy she was extensively worshipped from a very early period, and had many titles, such as *Patricia*, *Plebeia*, *Equestria*, *Virilis*, *Primagina*, *Publica*, *Privata*, *Muliebris*, *Virginensis*, &c., indicating the extent and also the minuteness of her superintendence. Particular honours were paid to her at Antium and Praeneste; in the temple of the former city two statues of her were even consulted as oracles. Greek poets and sculptors generally represented her with a rudder, as a symbol of her guiding power; or with a ball, or wheel, or wings, as a symbol of her mutability. The Romans proudly affirmed that when she entered their city she threw away her globe, and put off her wings and shoes, to indicate that she meant to dwell with them for ever.

Fortunate Islands, or ISLANDS OF THE BLEST. See ATLANTIS, AVALON, ANTILLES, BREN-DAN, CANARY ISLANDS, ELYSIUM, HESPERIDES.

Fortunatus is the title of one of the best people's books (*Volksbücher*) ever written. It originated about the end of the 15th century, though many of the tales and legends included in it are of much older date. The opinion that it was worked up into German from a Spanish or English original may safely be set aside. The substance of the book is that Fortunatus and his sons after him are the possessors of an inexhaustible purse of gold and a wishing-cap, which however, in the end, prove the cause of their ruin. The moral is that worldly prosperity alone is insufficient to produce lasting happiness. The oldest printed edition of the book now extant bears the date 1509. Later German editions mostly bear the title, *Fortunatus, von seinem Seckel und Wunsch-hutlein*. It has been reprinted in the third volume (1846) of Simrock's *Deutsche Volksbücher*. Versions of the story have appeared in French, Italian, Dutch, Danish, Swedish, and even Icelandic. The first to dramatise the subject was Hans Sachs, in *Der Fortunatus mit dem Wunschseckel* (1553), after whom comes the English Thomas Dekker, with his *Pleasant Comedie of Old Fortunatus* (1600), a work which had the honour to make its reappearance in German about the year 1620. The most poetical edition of the story is that given by Tieck in his *Phantasia*. See Schmidt, in Ersch and Gruber's *Encyklopädie* (sect. 1, vol. xlv.).

Fortune, ROBERT, a botanist and traveller in China, was born in the county of Berwick in 1813. After serving an apprenticeship as a gardener, he obtained employment in the Royal Botanic Garden at Edinburgh, and afterwards in the gardens at Chiswick. His real life-work began, however, in 1843, with the first of his journeys to China, on behalf of the Botanical Society of London. The results of this journey, the fruits of his observation of the flora of the country, its tea and cotton culture, appeared in 1847 in *Three Years' Wanderings in Northern China*. He subsequently visited China on three separate occasions, to study the methods of tea-cultivation, to carry plants from that country to India, and to collect seeds and plants for the government of the United States. *Yedo and Peking* (1863) was written after his fifth and last journey to the East. His other two books are *A Journey to the Tea Countries of China* (1852), and *A Residence among the Chinese* (1857). Fortune was for a few years director of the Botanical Gardens at Chelsea. He died 16th April 1880.

Fortune-telling. See DIVINATION, PALM-ISTRY, and GYPSIES.

Fortuny y Carbo, MARIANO, an eminent Spanish painter, was born at Reus in Tarragona, in 1839, and studied in the Academy of Barcelona and in Italy. When Spain declared war against the sultan of Morocco, Fortuny followed the army

to Africa, and filled his portfolios with studies of Eastern life. He received a commission for his 'Battle of Tetuan,' which now hangs in the Chamber of Deputies, Barcelona; but the subject was little to his taste; and, disputes having arisen, this large work was never quite completed. It was the domestic and ceremonial aspects of Eastern life that Fortuny chose to portray, and these mainly for their purely artistic possibilities; the painter treating his subjects simply as colour-schemes made up of dusky countenances, and gorgeous draperies, and vivid sunlight. His touch was particularly incisive and dexterous, and the effects he aimed at were those depending on the sparkle and brilliancy of points of potent, infinitely varied colour. He afterwards stayed much in Paris, Granada, and in Madrid, where he studied the great Spanish masters, and married the daughter of Madrazo, the director of the Academy. The preliminaries of his own wedding suggested to the painter his celebrated picture of 'The Spanish Marriage,' and among other of his later works are his 'Book-lover in the Library of Richelieu' and 'Academicians choosing a Model.' He also left some etchings of Eastern subjects. He died at Rome, 21st November 1874. See monographs by Davillier (illus. Paris, 1875) and Yriarte (Paris, 1885).

Fort Wayne, capital of Allen county, Indiana, at the confluence of the St Joseph and St Mary's rivers, which form the Maumee, and on the Wabash and Erie Canal, 148 miles ESE. of Chicago. It is an important railway centre, and has several railway workshops, foundries, and manufactures of organs, woollens, and engines. It is the seat of a Catholic bishop, and contains a Catholic hospital, convents, and academies, besides several colleges of other churches. Pop. (1870) 17,718; (1880) 26,880; (1890) 35,392; (1910) 63,933; (1920) 86,549.

Fort William, a police-burgh of Inverness-shire, near the head of salt-water Loch Linnhe, the west base of Ben Nevis, and the south end of the Caledonian Canal, 66 miles SSW. of Inverness. A fort, built by Monk in 1655, and rebuilt in 1690, was vainly besieged by the Jacobites in 1746, about 1860 dismantled, and in 1890 demolished. Fort William, long one of the keys of the Highlands, is now a tourist centre. Pop. 2000.

Fort William, a port of Ontario, Canada, on Lake Superior, 420 miles from Winnipeg, is the connection between the eastern and western sections of the Canadian Pacific Railway, and has a large trade, principally in grain; pop. 20,500.

Fort William (INDIA). See CALCUTTA.

Fort Worth, capital of Tarrant county, Texas, on the west fork of the Trinity River, 30 miles W. of Dallas, is a railway centre, with flour-mills, iron and oil industries, helium works, and stockyards; pop. (1880) 6663; (1910) 73,312; (1920) 106,482.

Forty, a number regarded with superstitious veneration alike by Jews and Moslems, prominently figures in the Bible and in Mohammedan writings. To cite some interesting examples from the notes to Mr W. A. Clouston's *Group of Eastern Romances and Stories* (privately printed, 1889): The Flood continued 40 days (Gen. vii. 17); Isaac was 40 years old when he took Rebekah to wife (Gen. xxv. 20), and Esau was of the same age when he wedded the two Hittite damsels (Gen. xxvi. 34); Joseph and his kinsmen fasted 40 days for their father Jacob (Gen. l. 3); thrice Moses fasted 40 days (Exod. xxiv. 18, xxxiv. 28; and Deut. ix. 9-25); during 40 days the Hebrew spies searched Canaan (Numb. xiii. 25); the Israelites were condemned to wander in the wilderness 40 years (Numb. xiv. 33); Eli judged Israel 40 years (1 Sam. iv. 18); Goliath defied the

Hebrew army 40 days (1 Sam. xvii. 16); David and Solomon each reigned 40 years (2 Sam. v. 4; 1 Kings, ii. 11, xi. 42); Elijah fasted 40 days (1 Kings, xix. 8); Nineveh was to be destroyed after 40 days (Jonah, iii. 4); Ezekiel bore the iniquities of the house of Judah 40 days, a day for a year (Ezek. iv. 6); Christ was tempted by Satan in the wilderness after having fasted 40 days (Matt. iv. 2, and Mark, i. 13), and continued 40 days on earth after his resurrection (Acts, i. 3). For further biblical instances, see Exod. xxvi. 19; Josh. xiv. 7; Judges, iii. 11, viii. 28, xiii. 1; 2 Sam. xv. 7; 1 Kings, vi. 17, vii. 38; 2 Kings, viii. 9; Ezek. xxix. 11, 12; Acts, xxiii. 21; 2 Cor. xi. 24.

Moslems mourn 40 days for their dead, and they deem a woman ceremoniously unclean during 40 days after childbirth; among the Israelites the period was 40 days when she had given birth to a male child, and twice 40 in the case of a female child. In Moslem fictions the number 40 very frequently occurs; for instance, in the well-known Arabian 'Tale of the Third Calender,' his voyage is prosperous for 40 days; he is entertained by 40 fairy damsels who absented themselves for 40 days. In the ever-fresh tale of 'Aladdin and his Lamp,' when the magic palace has disappeared the sultan allows him 40 days to find it and the fair princess. In the Persian romance of *Nasir*, the hero is directed by the 'last will' of a pious hermit, whom he found dead in his cell, to spend 40 days in prayer for the restoration of the fairies' fountain; he shoots an arrow through a suspended finger-ring 40 times in succession; but his too expert archery caused an accident to the king, from which his majesty did not recover until he had been 40 days under medical treatment. In a subordinate story in the same romance poor Shah Mansur was in the power of a cruel sorceress for nearly 40 days; and in another interwoven story a young prince was tossed about in the sea in a boat for 40 days. The general number of a gang of robbers in Eastern tales is 40: we have a very familiar instance of this in the Arabian tale of 'Ali Baba and the Forty Thieves,' and another example is afforded us in the story of 'Ahmed the Cobbler' (Malcolm's *Sketches of Persia*), where the king's treasury is plundered by 40 robbers.

In Wales 40 loaves of bread and 40 dishes of butter are a common quantity in the records of rent paid to the Bishop of Llandaff. The fee of a bard for his song was 40 pence when he was a disciple, and twice forty for a master. The unthrifty 'Heir of Linne,' according to the fine old ballad, tried to borrow 40 pence of John o' the Scales, who had become the owner of his lands.

In Athens the 'Forty' (four from each tribe) tried cases when the damages claimed were under ten drachmæ. See Aristotle, *Athenian Constitution*.

Forty-shilling Freeholder. See PARLIAMENT, FREEHOLD.

Forum, the name applied by the Romans to a public space, especially the market-place in a city, as the principal place of meeting where public affairs were discussed, courts of justice held, and money transactions carried on. In Rome the name applied particularly to the famous *forum* or *forum magnum*, the low level space extending from the foot of the Capitoline Hill to the north-east part of the Palatine. Unlike the *fora* of the emperors this was a slow growth, and was only possible after the valley had been drained by the great *cloaca*. The central space was the meeting-place of the plebs, *Comitia Tributa*; while the patricians, *Comitia Centuriata*, met on the Comitium, adjoining the Forum. See ROME.

Forum Competens, in Law, is the court to the jurisdiction of which the party is amenable.

Fos'cari, FRANCESCO, Doge of Venice during the most flourishing period of the Venetian power. Born about 1370, and elected doge in 1423, his ambition speedily involved the state in a conflict with Milan, which, however, in consequence of the doge's great military ability resulted in the aggrandisement of Venice by the Treaty of Ferrara (1433). The last years of the doge were embittered by the misfortunes that overtook his son, Giacompo, who was, by authority of the Council, three times tortured in his father's presence and banished, on the first two occasions on false charges, on the third occasion for having besought foreign intercession against the injustice to which he was being subjected. Giacompo died in Candia shortly after his last cruel torturing and banishment. The old doge was allowed to resign office in 1457, and died seven days later, on 1st November. Byron made the tragic history of father and son the subject of *The Two Foscari*.

Fos'colo, UGO, originally NICCOLO, an Italian author, was born in Zante, one of the Ionian isles, on 26th January 1778. His education was begun at Spalato, and completed at Padua, where Cesarotti inspired him with his first love for literature. A man of passionate temperament, and withal an ardent patriot, Foscolo was bitterly disappointed when by the Treaty of Campo Formio Venice was given to Austria, and his disappointment found vent in the *Lettere di Jacopo Ortis* (1802), a sort of political Werther. Still, believing that France was destined to liberate Italy, he served in the French armies, and was present at the battle of the Trebbia and the siege of Genoa. But, becoming finally undeceived as to Napoleon's intentions with regard to his native land, he returned to Milan, where he published in 1807 his best poem, *I Sepolcri*, a work composed in the spirit of the ancient classic writers, and remarkable for its smooth and polished versification. About this time he wrote a translation of Sterne's *Sentimental Journey*, and two tragedies, *Ajace* and *Ricciarda*, both showing political tendencies. In 1809 he was appointed to the chair of Eloquence in Pavia, and occupied the post until the professorship was suppressed in all the colleges of Italy. His inaugural address, *Dell' Origine e dell' Ufficio della Letteratura*, although full of the same love of classic beauty which marks the *Sepolcri*, is turgid and affected in style, like the man himself. When in 1814 the Austrians entered Milan, Foscolo withdrew to Switzerland, and in 1816 he went on to London. There some of his best writings were published—viz. *Essays on Petrarca*, *Discorso sul testo del Decamerone*, *Discorso sul testo di Dante*, and various papers in the *Quarterly* and *Edinburgh Reviews*. His last years were embittered by poverty and neglect. He died October 10, 1827, of dropsy, near London. His remains were finally deposited in the church of Santa Croce, Florence, in 1871. His works and letters were published at Florence in 12 vols. by Le Monnier (1850-62). See *Lives* by Pecchio (1836), Carrer (1842), Artusi (1878), Antona Traversi (1884), De Winkels (1885-86), and Chiarini (1910); *Studi* by G. Manacorda (1921).

Foss, or **FOSSE** (Lat. *fossa*, from *fodio*, 'I dig'), in Fortification, is a ditch or moat, either with or without water, the excavation of which has contributed material for the walls of the fort it is designed to protect. The foss is immediately without the wall, and offers a serious obstacle to escalating the defences. See **FORTIFICATION**.

Fossa et Furca. See **PIT AND GALLOWS**.

Fossano, a town of Piedmont, North Italy, picturesquely situated on a hill over the Stura, 15 miles N.E. of Cuneo by rail, with a cathedral, a 14th-century castle, and remains of the old town walls. Its streets have an antique and gloomy

appearance, the houses being built over low arcades, under which run the footways. It has an academy of sciences, a seminary, technical and veterinary schools, and manufactures of silk, leather, and hemp. Pop. 20,000. See **BORGOGNONE**.

Fossil (Lat. *fossilis*, 'dug out of the earth'), a term formerly applied, in accordance with its derivation, to whatever was dug out of the earth, whether mineral or organic. The term is now restricted to remains and relics of plants and animals which have become embedded by natural causes. These fossils may consist of the harder and more durable parts of animals and plants, or they may be merely the casts or impressions of such remains, or the footmarks or tracks which animals may have left behind them on some soft surface which has been subsequently covered up and consolidated. They occur in nearly all the stratified aqueous rocks, which have on this account been called Fossiliferous strata. It is difficult or impossible to detect them in metamorphic aqueous rocks, for the changes that altered the matrix have also affected the organisms, so as either almost or altogether to obliterate them. In the archæan schists they have escaped notice, if ever they existed; but they have been detected in schistose rocks of Palæozoic age in different parts of the world.

The conditions in which fossils occur are very various. In some Pleistocene beds the organic remains are but slightly altered, and are spoken of as sub-fossil. In this state are the shells in some raised sea-beaches, and the remains of the huge struthious birds of New Zealand, which still retain a large portion of the animal basis. In the progress of fossilisation every trace of animal substance disappears; and if we find the body at this stage, without being affected by any other change, it is fragile and friable, like some of the shells in the London clay. Most frequently, however, a petrifying infiltration occupies the cavities left in the fossil by the disappearance of the animal matter, and it then becomes hardened and solidified; hence fossils were formerly, and still often are, called *petrifications*. Sometimes the whole organism is dissolved and carried off by water percolating the rock, thus leaving a cavity which may be filled up with calcite, pyrite, gypsum, flint, chalcedony, or some other mineral; and we thus obtain the form of the organism, with the markings of the outer surface, but not exhibiting the internal structure. Not infrequently, as in the case of shells of molluscs, &c., after the soft parts of the organism have been removed and replaced by inorganic matter (either before or after burial), the shell itself may be dissolved out so as to leave a cavity which shows the mould of the outer surface of the shell, and a cast of the interior. If the shell-space is not subsequently filled up by introduced mineral matter, the internal cast lies loose in the cavity like the kernel of a nut. Most commonly, however, the shell itself is replaced by hydrated mineral matter. The most advanced and perfect condition of fossilisation is that in which not only the external form, but also the most minute and complicated internal organisation, is retained; in which the organism loses the whole of its constituents, particle by particle, and as each molecule is removed its place is taken by a molecule of another substance, as silica or pyrites. In this way we find calcareous corals perfectly preserved in flint, and trees exhibiting in their silicified or calcified stems all the details of their microscopic structure—the cells, spiral vessels, or disc-bearing tissue, as well as the medullary rays and rings of growth.

PTERIDOSPERMS.—As the name indicates, a group of plants forming a link between ferns and seed-bearing plants. Known only in the fossil condition, they undoubtedly formed one of the

dominant types of vegetation during Carboniferous times; indeed, evidence accumulated in recent years by the patient researches of palaeobotanists shows that the group embraces the majority of the so-called 'ferns' of that age. The distinguishing feature in their structure is that their leaves, to all appearance ordinary foliage leaves, yet bear seeds. The composite character of these plants is well seen in a common type such as *Lyginodendron*, the leaves of which belong to the old 'fern' genus, *Sphenopteris*. The roots of *Lyginodendron* in the young condition closely resemble those of Marattiaceous ferns; at a later stage, unlike ferns, they show secondary thickening, and thus show affinities with the roots of gymnosperms. The general anatomy of the stem suggests at once the Cycad type, but the occurrence of centripetal wood in the primary bundles indicates a more primitive character. (In other genera of Pteridosperms the stem is decidedly fern-like.) *Lyginodendron* further resembles ferns in the general aspect of its foliage, and in the fact that its reproductive organs are borne directly on the leaves; the seed in its complex organisation, however, except that it does not contain an embryo, closely approaches that of a typical gymnosperm. Among the ever-increasing number of Carboniferous 'ferns,' now regarded as Pteridosperms are included other common genera such as *Neuropteris* and *Alethopteris*. For fossil ferns proper, see FERNs.

FOSSIL FORESTS have been frequently observed in the Coal-measures. The seams of coal having in general been formed from the vegetation of the locality where they occur, it is to be expected that when the coal is removed the stools and roots of the trees will be observed in the immediately subjacent bed of clay or shale—the ancient soil. Such a forest was laid bare in an open work at Parkfield Colliery, near Wolverhampton, in 1844. In the space of about one-fourth of an acre appeared the stumps of 73 trees, with their roots attached. The trunks, broken off close to the root, were lying prostrate in every direction, often crossing each other. One of them measured 15, another 30 feet in length, but they were generally shorter. They were invariably converted into coal, and flattened to the thickness of 1 or 2 inches. The upright stems show that some of them had a circumference of more than 8 feet. A fossil forest was uncovered near Glasgow in 1887. Similar fossil forests have been observed in the coalfields of Nova Scotia, and have been carefully described by Lyell, Logan, and Dawson. The usual height of the trees observed by Lyell was from 6 to 8 feet; but one tree was about 25 feet high, and 4 feet in diameter. Brongniart describes the remains of a fossil forest preserved in an upright position, in strata of micaceous sandstone, belonging to the Coal-measures at St Etienne, near Lyons. Though most abundant in strata of the Carboniferous period, fossil forests have been observed in other formations. The Dirt-bed (q.v.) of the Lower Purbeck series is the remains of an ancient forest. Instances are also abundant in strata of later age.

The remains of ancient forests belonging to a geologically recent period are to be found in and underneath beds of peat. There is good evidence that some kinds of peat had their origin in the destruction of forests. Trunks and branches of oak, hazel, fir, &c. are found in them, and the roots of the trees may be traced in the underclay. Round the coasts of the British Islands and the opposite shores of the Continent remains of ancient forests are frequently to be seen at low-water, the stools of the trees evidently occupying the place of growth. The occurrence of these so-called 'submerged forests' shows that within recent times

there has been a loss of land in north-western Europe. See GEOLOGY, PALAEONTOLOGY, PLEISTOCENE SYSTEM, &c.

The discussion of fossil footprints, the tracks of animals or other moving things, on mud or sand now indurated into rock, is sometimes called Ichnology.

Fossombrone, a town in the Italian province of Urbino-Pesaro, on the Metauro, here spanned by a fine modern bridge, 10 miles E. of Urbino, has a cathedral, mineral spring, and silk-works. Here stood the *Forum Sempronii*, of which interesting remains have been found. Pop. 11,000.

Foster, BIRKET, artist, was born at North Shields, of Quaker parentage, 4th February 1825, but from his sixth year was brought up in London. He could draw before he could speak, and, as pupil to Landells, the wood-engraver, from 1841 to 1846, he produced a large number of subjects for wood-engravings, the earliest for Mr and Mrs S. C. Hall's *Ireland* (1843), and many for the *Illustrated London News*. Afterwards, in conjunction with John Gilbert, he illustrated *Evangeline* and many of the poets, his share being dainty poetic landscapes and rustic scenes, nowhere better exemplified than in his *Pictures of English Landscape* (1862). Between them the two did more than any others to educate popular taste. In 1859 Foster exhibited the first of many water-colours, and in 1860 was elected an associate, in 1861 a member of the Water-colour Society. He died at Weybridge, 22d March 1899. See Life by Cundall (1906).

Foster, JOHN, 'the essayist,' was born in the parish of Halifax, Yorkshire, 17th September 1770. Elder son of a yeoman-weaver, he was trained for the ministry at Brierly Hall and the Baptist College in Bristol, but, after preaching for twenty-five years with very indifferent success to small congregations at Newcastle, Dublin, Chichester, Frome, &c., in 1817 he finally relinquished the pastoral office, to devote himself wholly to literature. His *Essays, in a series of Letters* (1805), were only four in number—the best known that 'On Decision of Character'—yet they showed him, said Mackintosh, 'to be one of the most profound and eloquent writers that England has produced.' In 1808 Foster married the Miss Maria Snooke to whom they were originally addressed. In 1819 appeared his celebrated *Essay on the Evils of Popular Ignorance*, in which he urged the necessity of a national system of education. Between 1806 and 1839 he contributed 184 articles to the *Eclectic Review*, 59 of which were edited by Dr Price in 1844. He died 15th October 1843, at Stapleton, Bristol, his home for twenty-two years. Foster was a man of deep but sombre piety. His thinking is massive and original; and at times, when his great imagination rouses itself from sleep, a splendour of illustration breaks over his pages that startles the reader by its beauty and suggestiveness. See his Life by Ryland (1846).

Foster, SIR MICHAEL (1836–1907), born at Huntingdon, and bred at University College, London, was professor of Physiology there, and in 1883–1903 at Cambridge. Secretary of the Royal Society and President of the British Association, he wrote a text-book and a history of the science he did so much to extend. He was elected M.P. for London University in 1900.

Foster, STEPHEN COLLINS, song-writer, was born in 1826 in Pittsburgh, Pennsylvania, and in 1842 was still a merchant's clerk in Cincinnati. Of more than a hundred negro melodies and sentimental ballads, the best known are 'The Old Folks at Home,' 'Nelly Bly,' 'Uncle Ned,' 'Old Dog Tray,' 'Gentle Annie,' 'Old Kentucky Home,' 'Willie, we have missed you,' and 'Come where my Love lies dreaming,' the airs and words of

which alike were his own composition. He died in New York, 13th January 1864.

Fosterage, the relation which arises when children are nursed and brought up by others than their own parents, may anywhere establish a very close bond between foster-parents and foster-children. But in ancient Ireland, under the Brehon Laws (q.v.), the systematic fosterage of the children of the wealthy in poor families, and their education there from infancy till the age of thirteen in the case of daughters and seventeen in the case of sons, was recognised and organised in the most elaborate manner, the respective duties and privileges being carefully specified and guarded. Thus, the foster-parents were entitled not merely to the fosterage fee, but to support in their old age from the foster-child; the foster-father was liable to mulcts incurred by the foster-child; and, if the foster-child was found to have been improperly or imperfectly educated in any of the specified branches, the foster-father had to refund the fees in due proportion.

Fotheringhay, a village of England, in Northamptonshire, on the river Nen, 9 miles SW. of Peterborough. In the ancient castle of Fotheringhay, founded shortly after the Conquest, Mary, Queen of Scots, was beheaded in 1557. It was allowed to fall into decay after the accession of James I. to the throne of England.

Foucault, JEAN BERNARD LÉON, French physicist, was born in Paris, 18th September 1819. His first work in the physical sciences was the improvement of Daguerre's photographic processes, and his next a series of investigations, conducted in co-operation with Fizeau, on the properties of light. Continuing his optical inquiries, he was enabled to demonstrate in 1850 that the velocity of light is greater in air than in water, and that in different media the velocity varies inversely as the refractive indices of the respective media. For his remarkable proof in 1851 of the rotation of the earth by means of a freely-suspended pendulum, see PENDULUM. Two years after his appointment (1855) as physical assistant in the observatory at Paris Foucault invented his polariser; and two years later (1859) his reflector for the great telescope at Paris was completed. Foucault also invented apparatus for the better application of the electric light, and showed that the sun may be viewed without injury to the eyesight if the object glass of a large telescope be covered with a thin film of silver. He died at Paris on 11th February 1868. Foucault edited the scientific part of the *Journal des Débats* from 1845, and was elected a foreign member of the Royal Society of London in 1864. His papers were printed in *Comptes Rendus* (1847-69). Compare also *Recueil des Travaux Scientifiques de Foucault* (ed. by Gariel and Bertrand, 1878).

Fouché, JOSEPH, Duke of Otranto, minister of Police under Napoleon, was born at Nantes, 29th May 1763. Although educated for the church, he hailed the Revolution with extravagant delight; and, on being elected to the National Convention in 1792, attached himself to the extreme party of the Mountain, and voted for the execution of Louis. He was commissioned by the Committee of Public Safety to castigate the obdurate city of Lyons (1794), and in that business rivalled his associates, Collot d'Herbois and Couthon, in cruelty and bloodthirstiness. In 1794 he was expelled from the National Convention as a dangerous Terrorist. Yet in September 1799 he had so far recovered ground that he was appointed minister of Police, a post which he held, though with several interruptions, down to 1815. Having made himself indispensable to Napoleon, whom he materially assisted during the revolution of 18th

Brumaire (5th November 1799), he proceeded to organise a system of police espionage; but this soon grew intolerable to the First Consul, who in 1802 abolished the ministry. In compensation Fouché was nominated senator of Aix, and rewarded with a large sum of money. Yet two years later Napoleon found it necessary to reinstate him in the office. Once more dismissed by the emperor in 1810, Fouché, after a period of flight in Tuscany, received the appointment of governor-general of Laibach and Rome (1813), and then of ambassador at Naples. Once more he was restored to his former post by Napoleon after his return from Elba, but seeing the downfall of the latter to be inevitable, he made terms with the Bourbons. Under Louis XVIII. he retained his position until the king was constrained by the popular voice to dismiss him in September 1815. Appointed ambassador to Dresden, he was there struck in 1816 by the decree of banishment pronounced against the executioners of Louis XVI.; and henceforward he led an exile's life at Prague, Linz, and Trieste, where he died, 25th December 1820. Fouché was a man with one aim only, his own political success. Unscrupulous, yet politic and sagacious, crafty, and fond of intrigue, he made an admirable head of police in the troublous days of Napoleon's reign, and by the firmness and skill which he displayed in the internal government of France, which was left almost entirely in his hands during the emperor's absence on his many campaigns, he was largely instrumental in preserving his country from anarchy. The *Mémoires de J. Fouché* published (4 vols. 1823-29) were declared not genuine by his sons—though Fouché was known to have composed *mémoires* during his last years of banishment. The standard Life is that by Madelin (2 vols. 1901).

Fougasse, an explosive mine so arranged as to hurl a volume of stones in the faces of an attacking force.

Fougères, a town in the French department of Ille-et-Vilaine, 23 miles by rail N. of Vitré (on the main line from Paris to Brest). It has a picturesque old castle, a college, and considerable manufactures of bootmakers' materials, sailcloth, and leather, besides granite-quarries. Here the Vendean royalists defeated the republicans in November 1793. Pop. 21,000.

Foula, a lonely island of Shetland, 16 miles WSW. of the nearest point of the mainland. Measuring $3\frac{1}{2}$ by $2\frac{1}{2}$ miles, it is 5 sq. m. in area, and attains in the Sneug a maximum altitude of 1372 feet. Foula is chiefly remarkable for the Old Red Sandstone cliffs on its north-west side, which, rising almost sheer from the sea to a height of 1220 feet, are unmatched for grandeur in the British Isles. They are denized in the breeding season by myriads of seawolf—puffins, kittiwakes, and the rare great skua or 'bonxie' (*Lestris catarractes*), which formerly was preserved by the islanders to keep down the eagles. The only landing-place is at the fishing hamlet of Ham, on the south-east. Foula was the last island where the old Norse tongue lingered on into the 19th century. It has Congregational and Established chapels. The population is about 150. See Tudor's *Orkneys and Shetlands* (1883).

Foulahs. See FULAHS.

Fould, ACHILLE, French financier and politician, was born in Paris, 31st October 1800, of Jewish parents. Early in life he was initiated into financial business in his father's bank. His political career began in 1842 by his election to the Chamber of Deputies for the Basses-Alpes. After the revolution of 1848 Fould accepted the new régime of the republic, and rendered considerable service to the provisional government in its financial

affairs. During the presidency of Louis Napoleon he was four times minister of Finance between 1849 and 1852. Whilst in office Fould gave the first impulse to the foundation of the *Crédit Mobilier*. Early in 1852 he finally resigned, in consequence of the confiscation of the property of the Orleans family. The same day, however, he was created a senator, and shortly afterwards returned to power as minister of state and of the imperial household, which position he held until 1860. In 1861 he was reappointed finance minister, and retained that post until 1867. On the 5th October following he died at Tarbes.

Foulis, ROBERT and ANDREW, Glasgow printers, were born the one in 1707, the other in 1712. Robert for some years practised as a barber, but meanwhile attended Professor Hutcheson's lectures on moral philosophy. Andrew had been bred for the ministry. In 1741, after two tours with his brother in England and France, Robert set up as a Glasgow bookseller, in 1743 was appointed printer to the university, and between 1742 and his death published 554 works—classics, translations, poetry, plays, &c. The most celebrated are the 'immaculate' *Horace* (1744), which contains, however, six misprints, and the splendid folio *Homer* (4 vols. 1756-58). With the view of promoting the fine arts in Scotland, Robert, after a fourth visit to the Continent, established in 1753—fifteen years before the foundation of the Royal Academy—an academy at Glasgow for engraving, moulding, modelling, and drawing. During the first ten years of its existence this institution produced 1112 prints, besides statues, busts, oil-paintings, and crayons; David Allan owed to it his early training. But the heavy attendant expense led to the decline of the printing business, and the death of the quiet, unvarying Andrew on 18th September 1775 proved the finishing blow. Eight months later Robert sold off his collection of 'old masters' at Christie's in Pall Mall; when all costs were defrayed the balance in his favour was just fifteen shillings. He died suddenly in Edinburgh, on his way back to Glasgow, 2d June 1776. For a full account of this *par nobile fratrum*, the 'Scottish Elzevirs,' see Richard Duncan's *Literary History of Glasgow* (Maitland Club, 1831; new ed. 1886).

Foundation. By this term is generally meant the ground on which the walls of a building rest. But of the walls themselves, whether of brick or stone, the lower courses, or those under the surface of the ground, are called foundation courses. The first thing to determine regarding the site for a building is whether the ground is natural or artificial. By the latter is understood some deposit of waste material, such as loose earth or builder's rubbish, which has been used to level up a piece of ground or put down for some other purpose. It is always necessary to sink the foundation trenches or tracks through made-up ground till the natural surface is reached. Supposing that on the site chosen there are no springs of water, and that it is well drained, then there is a likelihood that whatever the natural foundation, whether of rock, clay, sand, or gravel, it will be a safe one. Sometimes, however, even with these, some means has to be taken to prevent unequal yielding under the pressure of the walls. There may, for example, be hard and soft parts on a piece of ground of the same general character.

In the case of compressible soils of whatever nature the walls require a sufficiently thick bed of Concrete (q.v.) underneath them. More rarely Piles (q.v.) are driven in to support a platform upon which the walls rest, and sometimes inverted arches are used for distributing pressure over a foundation where it would otherwise come only on a few points.

Except where a building is erected on solid rock, what are called 'footings,' or, in Scotland, 'scarce-ments,' form the first or foundation courses of the walls. Stone footings consist of large flat-bedded stones, which in the lowest course are generally twice as broad as the wall above is thick. Two or more of these projecting courses are first laid, which give a stepped section to those portions of the walls underground. Brick footings resemble those of stone, only in them there are, of course, more joints from the smaller size of bricks. For foundations under water, see CAISSON, COFFER-DAM.

Foundations. See CHARITIES, CORPORATION.

Founder, also called LAMINITIS, consists of inflammation of the vascular sensitive laminae of the horse's foot. It is sometimes met with in cattle, but rarely in sheep, the corresponding structures being in them less developed. Occasionally the laminae are strained from severe exertion; more frequently they suffer from the morbid effects of cold, which is especially injurious after excitement and over-fatigue. Very commonly also they become inflamed from their close sympathy with diseases of the digestive organs, often following engorgement of the stomach or bowels. All the feet are sometimes affected, more usually the fore-feet only. They are hot and tender; the animal stands as much as possible upon his heels; trembles and groans when moved; and is in a state of acute fever and pain. Except when following super-purgation or internal disease, bleeding is useful. The shoes must at once be removed, and the toes, if long, reduced, but no further rasping or cutting is permissible. The feet must be enveloped in hot bran poultices, and kept off the hard ground by a plentiful supply of short litter. Soap and water clysters, repeated if necessary every hour, usually suffice to open the bowels, which are very irritable; and physic, if required, must therefore be used with extreme caution. Two drachms of aloes is an ample dose in founder. Have the strain taken off the inflamed laminae by getting the animal if possible to lie down, or, if he be afraid to do so, let him be 'cast' and kept down. As a rule when once down he will, from the relief to pain, often remain in the recumbent position; he should then be turned at least twice a day, and his bedding kept dry and clean to prevent chafing of the skin or 'bed-sores.' After the acute symptoms pass, thin heeled shoes, barred or plain, as suit the feet, should be put on, cold applications made to the feet, and then a mild blister put round the coronet.

Founding, or METAL-CASTING, is the art of working metals by pouring them, while in a fluid condition, into moulds in which they solidify and harden into the form of the mould which they fill. In general the terms are restricted to metal-work; but glass, plaster, cement, wax, gutta-percha, &c. are cast in moulds precisely in the same manner as the metals.

Casting is the most important of all the operations by which metals are fashioned into useful or ornamental forms; but there are certain metals which cannot be in practice treated by this process. It is essential that the metal employed should be meltable at a temperature which can be reached in foundry practice, that it should flow freely, and should fill the mould well without forming air-bubbles in the mass. Malleable iron cannot be treated by casting, on account of the excessive temperature at which it becomes fluid; and neither copper nor aluminium becomes sufficiently limpid to flow and fill a mould properly. Iron-founding, in which the special form of pig-iron known as 'foundry pig' is used, is the greatest of metal-

casting industries; after which come brass-founding, bronze-casting, zinc, German silver, gold and silver casting, and typefounding and stereotyping. The last two will be dealt with under their own proper heads, and the casting of the minor metals will receive such notice as they require in connection with the metals themselves.

The general process of founding or casting embraces numerous and complex operations connected with (1) the preparation of a mould or form into which the molten metal is run, (2) the melting of the metal or alloy, and (3) the pouring of the molten metal into the mould, in which it solidifies and hardens. According to the form, size, and intricacy of the object to be cast, and the nature and value of the metal used, the variations of working are very many, and it will not be possible here to describe more than two or three typical processes.

Bronze-casting is the most ancient of all metallurgical arts, and an outline of its development may serve to illustrate the processes employed in dealing with that alloy. The earlier forms of bronze axe used by prehistoric man were solid castings made in moulds, which consisted of two flat stones, having in the faces of each hollowed-out depressions which corresponded to two equal halves of the axe. The stones, when placed accurately face to face, had thus between them a hollow space which represented the form of a perfect axe, and into that hollow from the outer surface a channel or 'gate' was formed, by which the molten metal was poured in, till the hollow or mould was filled up. In later times, with the view of saving valuable metal, the practice was introduced of forming a core within moulds of large objects, around which the bronze was poured, which thus formed only an outer surface or skin. Iron appears to have been the material at first selected as suitable for such cores. But at a very early period the Greek sculptors discovered the art of casting their figures, &c. so that the core around which the metal flowed was removable, thus forming hollow castings. By whatever process the early artists worked they were able to produce castings which for beauty of surface, intricacy of pattern, size of casting, and economy of metal cannot be excelled with all the resources of modern ingenuity. Their process was probably that employed to the present day for the finest products of bronze-casting, known as *cire perdue*. In this process a rough model of the statue or other object to be cast is formed slightly smaller than the work to be cast. This model is coated over with beeswax; and to the wax surface the most finished form and touches of the artist are given. The whole surface then receives two or three coatings of a potter's slip or fine cream of ground brick, clay, and ashes, which forms a closely adherent skin around the wax. Then the mould is built up of clay, packed around all the parts to form a solid mass, which is clamped up within a strong iron framework. At certain intervals iron pins are stuck through the clay and wax into the central core, and suitable 'gates' are made for pouring in the bronze and allowing the wax to escape. The clamped-up mass is now placed in the furnace, and slowly heated up till all the wax runs out, and the clay of both mould and core are dried and sufficiently baked. The space at first occupied by the wax is now vacant, and it only remains to pour in molten bronze to occupy the space and assume the form and the thickness of the original wax. In modern bronze-casting for which the *cire perdue* process is not employed, objects of large size, such as heroic figures, are cast in sections, which have afterwards to be fused together at their edges. Models in plaster of the

separate pieces are first made, from which moulds in sand and plaster are obtained. Within these moulds cores are cast, and these when baked and dry are uniformly scraped down all over according to the thickness desired in the finished object. The cores so reduced are again placed and supported within the moulds, and thus there is a space between mould and core into which the molten bronze is poured. The various pieces are subsequently brazed together and finished. Some of the recorded works of early Greek sculptors were cast of gigantic proportions. The Colossus of Rhodes is variously stated at from 90 to 120 feet in height. There yet remains in the Hippodrome at Constantinople a pillar of bronze in the form of three twisted serpents, cast 479 B.C., which in its perfect condition was 20 feet high. Schwanthaler's figure of 'Bavaria' in Munich, finished in 1850, stands 67 feet in height, and contains nearly 63 tons of bronze. 'La Vierge du Puy,' by Bonnassieux, is 51 feet high, and contains about 100 tons of bronze. For Bartholdi's 'Liberty' and other famous bronze figures, see COLOSSUS.

Iron-founding, from the nature of its operations and the gigantic scale on which it is carried on, may be regarded as a separate and distinct industry. The large-grained, gray pig-iron, on account of the highly fluid condition into which it can be brought, is the material principally employed; but according to the size of the castings required and the purposes for which they are to be used mixtures of finer grained pig are also melted up. The metal is melted with coke in a round firebrick furnace called a *cupola*, the heat being urged by means of a powerful blast created by rotary blowers (superseding fanners). The molten metal is run from a tap at the bottom of the furnace into a malleable iron ladle lined with loam, from which it is poured into the mould through holes called *runners* or *gates*. When the mould is newly filled numerous jets of blue flame issue from as many small holes pierced in the sand. These perforations are necessary for the escape of air and other gases produced by the action of the hot metal on the mould. Care must also be taken not to have the mould too damp, otherwise steam is generated, which may cause holes in the casting, or even force part of the metal out of the mould. The casting remains covered up for a time in order to cool slowly, and is then removed by breaking away the sand and drawing out the core.

In the case of a fluted or otherwise ornamented pillar the pattern would require to be in at least four pieces instead of two, because it is only a plain pattern that will come out of the mould in halves without tearing away the sand. When a pattern is necessarily made in several pieces it is drawn out of the mould bit by bit, to the right or left as the case may be, and so parts from the sand without breaking it.

Suppose that a small ornamental vase were to surmount the pillar, the founder would prepare the pattern of this in a more elaborate manner. He would first mould it in wax or clay, from which a cast in plaster of Paris is made; from that again a cast is taken in an alloy of tin and lead, which, after being sharply chased and divided into the required number of pieces, is used as a pattern to cast from. All ornamental patterns, such as figures, scrolls, leaves, enriched mouldings, and the like, are made in this way, whatever metal the ultimate casting is to be produced in.

Very large engine cylinders, pans, and such vessels are cast in loam-moulds, which are built of brick, plastered with loam, then coated with blacking, and finally dried by means of a fire. This method is adopted with large plain objects where a pattern would be expensive, and when few castings

of one kind are required. Iron moulds, coated with blacklead or plumbago, are now used for water and gas pipe founding, which forms an extensive special industry. They are greatly more expensive than any other kind, but they enable the founder to dispense with a pattern, as, when once made into the required form, they are not destroyed like moulds of sand or loam at each casting.

For *chilled* castings, also, metal moulds or moulds partly metal and sand are employed. In these the molten iron solidifies and cools with great rapidity, owing to which it acquires extreme hardness, a quality of peculiar value for shot and for many purposes where wear-resisting properties are of more importance than toughness. In *malleable* castings the opposite effect of rendering the metal soft, tenacious, and partially malleable is obtained. For this end the finished casting is embedded in powdered hematite ore or other iron oxide, packed in an iron chest, and exposed for two or three days to a red heat in a furnace. Thereby the cast-iron parts with its carbon, and assumes the softness, tenacity, and infusibility of malleable iron. The process may be continued till the effect is produced throughout the mass acted on, or it may be stopped when merely a skin is decarbonised, leaving the core of unaltered cast metal.

In iron-casting, and especially in steel-casting, bubbles of carbonic oxide and other gases are formed, which partly escape and partly remain imprisoned in the mass, tending to render it vesicular and less sound than it might otherwise be. Various means have been adopted to promote the escape of imprisoned gases, and thereby to render the casting more homogeneous and strong. In Krupp steel the addition of silico-spiegeleisen to the cast metal acts favourably by stopping the evolution of the gases. To force out the gases the late Sir Joseph Whitworth in casting steel adopted the expedient of casting under pressure. While the metal was in a fluid condition he applied pressure of as much as from 6 to 9 tons per square inch over its surface, and by preventing the formation of air-bubbles he thereby obtained a remarkable increase in the strength of the castings so operated on.

The variety of articles produced by founding or casting are very numerous. Besides others incidentally alluded to, we may mention cylinders, cisterns, paper-engines, beams, boilers, pumps, and the heavy parts of machinery generally, gates, railings, lamps, grates, fenders, cooking-vessels, and the like in iron; cannon, many portions of machinery, and numerous ornamental objects in brass, bronze, and the more costly metals.

Machine-moulding.—Much moulding is now done by machinery of many different types. A gear-wheel moulding-machine requires only a pattern of two or three teeth to mould a complete toothed wheel.

Foundling Hospitals, strictly speaking, are institutions in which children that have been deserted by their parents or guardians are received to be nourished and cared for by private charity or at the public expense. Their primary purpose is to serve as a preventive of infanticide and the wilful procurement of abortion, and to counteract the temptation on the part of unmarried women to abandon their illegitimate offspring, and of married women to leave exposed on the streets children they are themselves either unwilling or unable to nurture and support. Although the practice of infanticide was largely prevalent amongst some of the nations of antiquity, especially the Greeks and Romans, amongst whom the father of a family possessed an almost absolute right of life and death over his children, even to selling them into slavery or to slaying them, nevertheless the state was not altogether careless of the preservation of foundlings

and abandoned children. Private persons were encouraged to take care of deserted infants, and to educate them, by decrees which assigned them as slaves to those who should thus adopt them. Of the rest—such as were not thus taken charge of—many were educated at the public expense. The ancient Egyptians, Jews, and Thebans (in Greece), however, looked upon infanticide as a crime; and this also was the sentiment of the ancient Germans. But from the time when Christianity became the state religion of the Roman empire a sensible change began to show itself amongst its leading peoples in relation both to infanticide and to the exposure of children. The more enlightened emperors, as Constantine, Valentinian, and Justinian, devised legislative measures for the prevention of both offences. But it was only when the church turned its attention to the matter seriously that the preservation of those unfortunates began to be carried out in a systematic way. In spite, however, of imperial edict and ecclesiastical exhortation, exposure and the selling of offspring, especially in times of public calamity or distress, still continued to be largely practised, more particularly in the Western empire. Iceland, *circa*. 1000, declined to accept Christianity unless the church permitted 'exposition' of children. The germ of the modern foundling hospital may perhaps be found in an institution which owed its existence to the Bishop of Tièves in the 6th century: in the cathedral porch a large marble basin was built, in which children might be placed, to be afterwards reared by members of the church under the superintendence of the ecclesiastical officers. Similar arrangements are mentioned in some of the capitularies of the Frankish kings. But the first well-authenticated instance of a foundling hospital, as we now understand the term, is one that was established at Milan in 787. From the end of the 11th to the end of the 14th century several institutions of a similar character were founded in some of the chief towns of France, Italy, and Germany. It is in France that they have been most thoroughly studied and organised.

At Paris foundlings were generally deposited in the porch of Notre Dame. For the reception of children so exposed Marguerite de Valois opened a special home in 1536, and nine years later the government afforded shelter to 136 orphans in the Trinity hospital. But, no provision being made for their sustenance, they were dependent upon the alms which their nurses begged on the streets or which they themselves could collect when old enough to go a-begging; till in 1552 the parliament of Paris set apart for their maintenance the proceeds of a special tax. Amongst these children the mortality averaged 90 per cent. About the same time the Bishop of Paris built another house of refuge for foundlings picked up within his diocese; this was known as the *Couche*. But the accommodation was insufficient, and children were selected for admission by lot, those who were not elected being generally left to die on the street. Subsequently the inmates of the *Couche* became the objects of a brisk traffic, children being sold to professional beggars, acrobats, and others at the fixed price of 20 sous each. These evils at length attracted the attention of St Vincent de Paul, who in 1638 established a more satisfactory home and a humane system of treatment. Out of this grew the celebrated Foundling Hospital of Paris, which was incorporated in 1670. With it the *Couche*, reformed and enlarged, was joined in 1688, and Marguerite de Valois's orphanage in 1772. Under the Revolution all illegitimate children and foundlings were virtually adopted by the state, which in 1793 issued a decree bestowing a premium upon all girls who should declare themselves to be the mothers of ille-

gitimate children, and, as the Emperor Trajan had done, proclaiming all such infants 'children of the country.'

At the Foundling Hospital of Paris children are admitted (since 1886) under conditions which allow any person to leave a child openly without giving an account of it; in fact, the system in vogue is that of indiscriminate admission under the cover of secrecy. The infants admitted belong to the following categories: foundlings proper—i.e. children deserted by parents who are unknown; children who are abandoned by parents who are known; and orphans left destitute, the general designation for them all being not *enfants trouvés*, but *enfants assistés*; besides these, the hospital also takes in children *moralement abandonnés*—i.e. incorrigible children sent by the law-courts, by the prefecture of police, or by their parents. The scope of the institution is not, however, confined to this; it also gives presents of money, baby-clothes, and cradles to mothers who are poor, and sends out nurses to give suck to the infants of such women as cannot themselves perform that service for their offspring. As a rule infants only remain in the establishment at Paris a short time—the average is four days; when adjudged strong enough to travel, they are sent with their nurses into the country, to be boarded with peasants or artisans. For the custody of each child the government pays a monthly subsidy, decreasing from 15 francs during the first year to 6 francs during the twelfth. Once that age is reached nothing further is paid; the child is then generally apprenticed to its foster-father if he is an artisan, or becomes his domestic servant if he is a peasant engaged in agriculture. The central administration, however, still keeps its eye upon these children through its provincial inspectors, nor does it lay down its guardianship or cease its surveillance of them until after they have attained twenty-one years of age. These inspectors also keep the provincial hospitals and the central hospital at Paris supplied with wet-nurses, recruited from the women of the countryside. Parents are allowed to reclaim a child at any time on satisfactorily establishing their title to it, and that without recouping the expense of rearing it. Also, persons who prove to the satisfaction of the hospital administrative authorities that their motives are sincere and laudable are allowed to adopt a child from amongst those whose parents are altogether unknown.

In the United Kingdom and Germany the care of foundlings is for the most part left to the active philanthropy of the charitable or to the operations of the poor-law administration. Britain lagged behind other lands in this form of philanthropy, though the idea of foundling hospitals had long been familiar. Christ's Hospital (1553) was originally a foundling hospital, but only for a short period. It is probable that an essay by Addison (*Guardian*, cv.) in 1713 prepared the way for the success of the project of Thomas Coram (q.v.), who after seventeen years of untiring effort founded in 1739 the institution known as the London Foundling Hospital, of which the real title is 'The Hospital for the Maintenance and Education of Exposed and Deserted Young Children.' The term 'Foundling' Hospital is indeed not strictly appropriate, but this famous institution claims more than passing notice.

The work began in Hatton Garden, but was transferred in 1745 to its present home in Guilford Street. The hospital quickly won support, and a notable feature of its early history is its association with the arts. Hogarth was a member of the original committee, and two of his finest paintings are in the hospital. The annual art exhibitions there led to the formation of the Royal Academy. Handel conducted annual performances of *The*

Messiah in the chapel, the funds profiting to the extent of £7000. Music has all along been cultivated at the Foundling, and the massed choir of children's voices lends attraction to the chapel services. The boys are taught musical instruments, and no less than some 80 per cent. enlist as regimental bandmen.

A disastrous episode in the early history of the hospital was its period of indiscriminate admission, aided by large subsidies from the state, when branch hospitals were established at Ackworth, Shrewsbury, Westerham, and elsewhere. Grave abuses arose, and after four years' trial indiscriminate admission ceased in 1760, the country hospitals being successively sold.

The system of admission now in operation has been found satisfactory. A child is admitted, if not over twelve months old, on personal application of the mother, who must have been deserted by the child's father, and whose previous character has been good. Children of married women and widows are not received. No money is accepted for admission. On reception children are put out to nurse with cottagers (usually outside London), and are brought back to the hospital at the age of five. Boys enlist or are apprenticed, &c., when fifteen. Girls become domestics at sixteen, and are visited from time to time. Rewards are given annually to deserving ex-Foundlings until they come of age. There are usually between 600 and 700 children in hospital and at nurse.

Great Britain possesses numerous orphanages and homes for waifs and strays.

Russia possesses two large foundling hospitals, one at Moscow, admitting 13,000 children per annum, and the other at Petrograd, which accommodates an annual average of 7500. Here infants prematurely born are reared in 'frames very like those used for melon culture,' padded inside, and surrounded outside with a jacket of hot water, so that the temperature may be kept uniform.

Italy has many foundling hospitals. Among the most notable are those at Rome (where a department of the ancient foundation San Spirito maintains about 3000 foundlings), Venice, and Florence. The methods followed at Florence were studied by Coram's committee when the London Foundling Hospital was being planned (*supra*). Foundling hospitals exist in most of the countries of Europe, particularly in Austria, Spain, and Scandinavia.

In the United States deserted children are for the most part sent to the almshouses, or are taken care of in private charitable institutions, like the foundling asylum of the sisters of charity, for instance, in New York city, established in 1869; the infants' hospital, established in 1868; the nursery and child's hospital; and the infant asylum, organised in 1871—all at New York. There are large foundling hospitals at Mexico, Rio de Janeiro, and at Buenos Aires (founded in 1774, with an annual average of about 1200 to 1300 inmates). China, it should be stated, has admirably conducted establishments for the care of destitute and abandoned children in nearly all the large cities of the empire.

During the early part of the 19th century it was customary for foundling hospitals to be provided with a revolving pillar or basket or wheel, a contrivance by means of which a child could be deposited at a foundling asylum without the person who left it there being seen or any questions asked. This apparatus, which was indeed first used at Marseilles about the beginning of the 13th century, was largely employed in France, Belgium, Italy, and elsewhere; and, though it has been almost entirely abolished, it still survives in a few foundling hospitals of Italy. And the new regulation put in force at the Paris hospital in 1886 is virtually

a return to the principle underlying the use of this apparatus—viz. secret and indiscriminate admission. The revolving box was condemned on the ground that it acted as an encouragement to parents to abandon their offspring, and thus weakened the sense of parental responsibility.

Foundling hospitals have been condemned on the ground of the great mortality which takes place in them. For instance, at London, when admission was indiscriminate, the death-rate was over 60 per cent.; and the Dublin hospital, which for several years from 1704 received from 1500 to 2000 children annually, was finally closed in 1835 on account of the excessive mortality, the death-rate being 4 in 5. Again, the asylums of Russia have for many years lost 50 to 60 per cent. of the infants annually sent to them; in Vienna it rose even as high as 75; and it stood at a high figure in France, Italy, and Portugal. But in the case of France and London at least a great improvement has been effected, the percentage for each being less than 4, except in the case of children under one year of age boarded in the rural districts in France. Another system of rearing—sometimes killing off—illegitimate children is known as baby-farming.

Found Property. See LOST PROPERTY.

Fountain, a basin or an artificial structure for the supply or the ornamental display of water. In civilised countries fountains have at all times been considered as public monuments of the greatest importance; and, where the source of their supply has not been provided by nature on the spot, immense labour and expenditure have been incurred to make up for the deficiency. The splendid Aqueducts (q.v.) of the Romans are instances of the important light in which they regarded the fountains of their cities. Every Roman town had at least one aqueduct, the water from which was distributed to as many fountains as the population required.

In early times utility was the first object of a fountain, and the ornamental features of the structure into and through which the water was led were strictly developments of their original utilitarian purpose. Springs were highly valued, especially in lands where water was scarce; many of them were associated with the names of saints, and sacred traditions accumulated around them. Sometimes, therefore, such springs were built around for protection, statuary figures of their patron saint were placed in niches, and artificial basins were provided to contain the water. In towns where a number of persons might require to draw at one time a large basin was erected with a pillar in the centre, from which pipes radiated all round—each with its separate jet to supply the running water—while the basin was used for washing the pitchers. Many examples of this kind of fountain remain throughout Italy and in the older German towns, of which the fountain at Viterbo and the Schöner Brunnen at Nuremberg may be mentioned as examples. The pillar is sometimes surmounted by a statue, or has one or more smaller basins with ornamental streams and jets of water falling from tier to tier. A beautiful fountain of this nature existed in the royal palace at Linlithgow, and a modern reproduction of it may be seen in front of Holyrood Palace at Edinburgh.

Where modern views of water-supply and sanitation are carried out, under which water is led into each household by gravitation, great public fountains have become purely ornamental structures.

Fontana Grande, Viterbo.

Small pillar fountains are yet commonly placed on streets and places of public resort for wayfarers, and similarly basin fountains are provided for horses and other animals. The Metropolitan Drinking Fountain Association was formed in London in 1859. Of ornamental fountains the most magnificent display is at Versailles. Paris also contains several very remarkable fountains, and in England the display at the Crystal Palace, Sydenham, is very fine. Chatsworth is remarkable for its fountains, one of which is said to throw a jet of water 267 feet high. Although Rome has lost four-fifths of the aqueducts which so lavishly supplied her with fresh water in the time of the Empire, she is still unsurpassed for the number, beauty, and utility of the public fountains which adorn her streets and palaces.

Fountains Abbey, one of the largest and best-preserved monastic edifices in England, in the West Riding of Yorkshire, 3 miles SW. of Ripon. Founded for Cistercians in 1132, it was not completed till the 16th century, so offers every variety of style, from Norman to Perpendicular. See Walbran's *Fountains Abbey* (Surtees Soc. 1863 *et seq.*).

Fountain Shell. See STROMEUS.

Fouqué, FERDINAND ANDRÉ (1828–1904), French petrologist and geologist, was born at Mortain (La Manche), studied at the École Normale in Paris, and became curator of the scientific museum. Afterwards he held various academic appointments, including a chair in the Collège de France, and took part in many expeditions. He did stratigraphical work for the French geological survey, but turned later to petrology and the study of volcanoes, especially to experimental research. He collaborated much with Michel-Lévy.

Fouqué, FRIEDRICH HEINRICH KARL, BARON DE LA MOTTE, German romanticist, was of Huguenot ancestry, and grandson of the Prussian general of the name (1698–1774) distinguished in the Seven Years' War. Born at Brandenburg, 12th February 1777, Fouqué served as Prussian cavalry officer in the campaigns of 1794 and 1813. The interval between these campaigns was devoted to literary pursuits in the country, and the rest of his life was spent alternately in Paris and on his estate at

Nennhausen, and after 1830 at Halle. He died in Berlin, 23d January 1843. Fouqué appeared first under the pseudonym *Pellegrin*, as author of *Dramatische Spiele* (1801). Noise legend and old French and German poetry attracted him most strongly; one sees this in his long series of romances, both prose and verse, which picture the life of mediæval Europe. These include *Sigurd* (1808), *The Magic Ring*, *Thiodulf the Iclander*, *Astanga's Knight*, *Sintram and his Companions*, *The Two Captains*, and *Undine*. His masterpiece is *Undine* (1811); its tender grace and fairy glamour are exquisite. Otherwise Fouqué is too often chargeable with all the extravagances of the romantic school. Straining after fantastic conceits, he seems fascinated by the antique life which he pictures, rather merely from its quaint contrast with modern manners than as a form into which the life of actual living men had shaped itself in bygone days. He himself edited a selection of his works (12 vols. Halle, 1841). His second wife, Karoline (1773-1831), is also known in Germany as a romance-writer.

Fouquet, CHARLES LOUIS AUGUSTE. See BELLEISLE.

Fouquet, or FOUQUET, JEHAN, French painter of the 15th century, best known as a miniaturist and book-illustrator, but excelling also in portraits and altar-pieces, was born at Tours about 1415. He visited Italy, painted a portrait of Pope Eugenius IV., returned to France, and was court painter to Louis XI. He probably died about 1485 or 1490. Owing much to Italian and Flemish art, he may be regarded as the founder of a French school. His most notable book-illustrations are those for a *Book of Hours* and for a *Josephus*. His portraits include Charles VII., Count Wilczek, and Jouvénal des Ursins. A diptych, formerly in Notre Dame de Melun, exhibits Agnes Sorel as the Virgin. See a work by G. Lafenestre (Paris, 1902).

Fouquet, NICOLAS, Viscount of Melun and of Vaux, and Marquis of Belle-Isle, finance minister under Louis XIV. of France, was born at Paris in 1615. Attaching himself closely to Mazarin, he received in 1650 the important appointment of *procureur-général* to the parliament of Paris, and three years later was advanced to be superintendent of finance. His rapid advance made him ambitious of succeeding Mazarin as first minister, and in order to secure himself friends and a party he distributed money with a lavish hand; but he had a formidable rival in Colbert. Fouquet's plans were, however, brought to nought; for in the first place Louis himself took the reins of power into his own hands when they slipped from the grasp of the dead cardinal, and in the second place, instigated thereto by Colbert, he suddenly arrested Fouquet in September 1661. After a trial extending over three years, Fouquet was sentenced to perpetual exile and the loss of all his property, but the sentence was afterwards altered to life-long imprisonment in the fortress of Pignerol, where he died 23d March 1680. As an example of the extravagance and gorgeous display made by Fouquet, it may be mentioned that shortly before his arrest he entertained the king at a banquet which cost 120,000 livres in his castle of Vaux, erected by him on a plan very similar to that afterwards embodied in the royal palace at Versailles. From the circumstance of his imprisonment at Pignerol, Fouquet, though he died in 1680, has been identified with the Man with the Lion Mask (q.v.; who died in 1703). See *Lives* by Chéruel (1865), Lair (1890), and Cheales (1899).

Fouquier-Tinville, ANTOINE QUINTIN, one of the most notorious actors in the French Revolution, was born in the village of Hérouelles, in

the department of Aisne, in 1747. Originally an attorney of dissolute habits, he ranged himself, on the outbreak of the Revolution, in the ranks of the most violent among the democrats. Appointed by Robespierre and Danton public prosecutor to the Revolutionary Tribunal on 10th March 1793, he superintended during the Reign of Terror, until 28th July 1794, all the political executions decreed by the tribunal. His performance of his duties was characterised by pitiless rigour, brutality, and callous indifference. He apparently regarded it as his mission to supply the guillotine with a regular supply of victims, and no bribes were able to turn him from his purpose. And he sent his friends, among them Robespierre, Danton, and Hébert, to execution in the same spirit in which he sent their enemies. On the overthrow of the Reign of Terror he was himself guillotined on 7th March 1795. See the *Life* by Alphonse Dumoyet (1912; trans. 1913).

Fourchambault, a town in the French department of Nièvre, 5 miles NNW. of Nevers, near the right bank of the Loire. There are large iron-foundries, nail-works, and wire-works. Pop. 5000.

Fourcroya, a neotropical genus of *Amaryllidaceæ*, nearly allied to *Agave* (q.v.), and yielding a similar fibre.

Fourier, FRANÇOIS MARIE CHARLES, a French socialist, was born at Besançon, 9th April 1772. His father, a prosperous draper, had him educated in the academy of his native town. The boy excelled in the studies of the school, especially geography, and was passionately fond of flowers and music. He regretfully abandoned his studies for a business career, which he followed with zeal and integrity in various towns of France. As a commercial traveller he also visited Holland and Germany, where with remarkable insight and accuracy he took note of everything interesting in climate, productions, and manners. From his father Fourier inherited a fortune of about £3000, but, having started business for himself at Lyons, he lost nearly all he had at the siege of that city by the Jacobins during the Reign of Terror (1793). He was even thrown into prison, and narrowly escaped the guillotine. After his release and two years' experience as a soldier he returned to a commercial career.

At a very early age Fourier had his attention called to the abuses of commerce. When only five he was punished for speaking the truth about certain goods in his father's shop; and in 1799, while employed in a house at Marseilles, he had to superintend the destruction of an immense quantity of rice held for higher prices, in the midst of a scarcity of food, till it had become unfit for use. Believing that a system which involved such abuses and immoralities must be radically evil, Fourier set himself to discover an entirely new social theory, which he elaborated chiefly in three considerable works. In 1808 he published his *Théorie des Quatres Mouvements et des Destinées Générales*; in 1822 his *Traité d'Association Domestique Agricole*; in 1829 *Le Nouveau Monde Industriel et Sociétaire*. Written under the most discouraging circumstances, these works for many years found few readers and scarcely any disciples; only the most ardent faith in his own principles could have carried him through so many difficulties. For the last ten years of his life he waited at noon every day in his apartments for the coming of the wealthy capitalist who should furnish means towards the realisation of his schemes. It was chiefly after the decline of the Saint-Simon movement that he gained a hearing and a little success. A small group of enthusiasts gathered round him; a journal was started for the advocacy of his views; an attempt to establish a society on his principles was made

in 1832 near Versailles, but without success. At Paris, October 8, 1837, Fourier died, poor, but warmly appreciated by a circle of devoted disciples. In his private life he seems to have been a model of kindness, simplicity, and integrity.

The great aim of Fourier is to reconstruct society on principles which are entirely new. But his social system is more or less moulded and coloured by his peculiar views on cosmogony and psychology. His views of God incline, though not decidedly, to pantheism. The will of God pervades the world as a universal attraction. Whereas Newton proved that this universal attraction governs one movement of the world, Fourier shows that it rules the world in all its movements, which are four—material, organic, animal, and social. From this law of universal attraction there follows a universal analogy, according to which everything in one department of the world has its parallel elsewhere.

Fourier believed that the world has scarcely yet reached the adult stage, having existed only seven thousand years, whereas it is destined to last for eighty thousand years, a long period of progress being followed by a corresponding period of decline. At present mankind is oppressed by an endless variety of evils, which he sums up in one obnoxious word, *civilisation*, and which are due to the fact that we have run counter to the Creator in pronouncing passions to be bad that are simply natural. To effect the passage from social chaos to universal harmony there is but one way—to give a free and healthy development to the human passions.

This brings us to the psychology of Fourier, who recognised twelve radical passions, with three points of attraction; five sensitive (tending to enjoyment), sight, hearing, taste, smell, and touch; four affective (tending to groups), friendship, love, ambition, and familism or paternity; three distributive (tending to series), the emulative, alternating, and composite. The meaning of the first nine is obvious enough. The emulative passion leads to intrigue, the alternating involves love of change; and the operation of the two might cause jealousy, disharmony, and war, were they not controlled by the composite passion and by a higher unity. Out of the free play of all the passions harmony is educed, like white from the combination of the colours.

But for the realisation of this ideal new social arrangements are necessary. These are provided in the *phalange*, an institution in which the interests of social union and individual liking are to be thoroughly reconciled. Each *phalange* was to consist of 1800 persons, a number sufficient to include the whole circle of human capacities, adequately various, and yet not too large for a convenient common life. The individuals constituting the *phalange* were to be arranged in groups of seven or more persons; from twenty-four to thirty-two groups were to form a series, and a number of series united to form a *phalange* of the requisite size. The pervading idea of the whole organisation was a harmonious social life combined out of the free play of the most varied likings and capacities. The dwelling of the *phalange* was the *phalanstère*, a vast, beautiful, and commodious structure in the centre of a highly cultivated domain, a square league in extent, where life would be arranged to suit every one, common or solitary, according to preference. As regards the institution of marriage Fourier would permit a freedom which would be subversive of such social order as now exists.

It is an obvious deduction from Fourier's principle of universal attraction that human life generally, and labour in particular, should be attractive. In the *phalange* labour is accordingly made attractive by constant regard to the likings and capacities

of every one, and by continual change of occupation. The results of labour were to be distributed in the following manner. Out of the common gain of the *phalange* a very comfortable minimum was apportioned to each member, and the remainder was divided into twelve shares, of which five went to labour, four to capital, and three to talent. In distributing the reward to labour, the reverse of the present method was to be followed—i.e. necessary labour would be best paid, useful labour would come next, and pleasant labour would be worst paid.

So convinced was Fourier of the beauty and practicability of his social system that he believed it only required to be understood in order to be universally appreciated, and that in a very few years his *phalanges* would cover the whole world. The *phalanges* would arrange themselves in convenient groups with a common chief, and all would finally be united in a great federation, with Constantinople as capital. There never has been the least symptom of the realisation of such a dream. The system of Fourier has so little touch with fact and reality that it is hardly worthy of serious discussion. His road to the social millennium is far too easy. Yet his works are full of ingenious suggestion; and his criticism of the existing social order is often most searching and pungent. His theories may still be very profitably studied by the social economist.

Fourier's complete works were published at Paris (6 vols. 1840-46; new ed 1870). The most eminent expounder of Fourierism was Victor Considérant, *Destinée Sociale* (1835); Gatti de Gamond's *Fourier et son Système* is an excellent summary. See also SOCIALISM; Pellam, *Fourier* (5th ed. 1871); L. Reybaud, *Réformateurs Modernes*; Sargant, *Social Innovators* (1839); and several works by Alhaiza (1890-95).

FOURIER, JEAN BAPTISTE JOSEPH, BARON DE, French mathematician, was born at Auxerre, 21st March 1768. He became a pupil, and in 1789 a professor, in the military school of his native place; was afterwards removed to the normal school in Paris, and then to the Polytechnic, and accompanied Bonaparte to Egypt in 1798. On his return to France he became a contributor to the *Description de l'Égypte*, and also wrote the historical introduction. At the same time (1802) he was made prefect of the department of Grenoble, an office which he held till 1815, and was created baron in 1808. After Napoleon's escape from Elba Fourier took up his abode in Paris, and devoted himself exclusively to science, becoming a member of the Academy of Sciences in 1816, and afterwards secretary for life, conjointly with Cuvier. He died at Paris, 16th May 1830. His most famous work is the *Théorie Analytique de la Chaleur* (Paris, 1822), in which he applied new methods of mathematical investigation. An allied subject is discussed in his treatise on the temperature of the globe (1827). His analysis of Determinants, distinguished both for its substance and manner of exposition, and left unfinished at his death, was completed and published by Navier (Paris, 1831).

Four Lakes, a chain of deep lakes (Mendota, Monona, Waubesa, and Kegonsa) in Dane county, Wisconsin, connected by short outlets. Madison, the state capital, stands on an isthmus between Mendota and Monona.

Four Masters, ANNALS OF THE, an historical work composed in the Irish language, at the monastery of Donegal, by Michael O'Clery, a Franciscan monk, who enjoyed some reputation as a trained antiquary and historical writer. The work, which covers the history of Ireland from 1172 to 1608, with additions bringing the narrative down to 1616, was begun in the year 1632 and completed in 1636. Michael O'Clery was assisted in the work

of compilation and copying by his brother, Conary O'Clery, by a relative, Cucogry O'Clery, and by Cucogry O'Duigenan; hence the title of the book. See the edition (text and Eng. trans.) by Donovan (3 vols. Dublin, 1848).

Fournies, a town in the French dep. of Nord, 12 miles SE. of Avesnes by rail, with mines, iron-works, and mills. Pop. 11,000.

Fowey, or FOY, a municipal borough and old port of Cornwall, on the river Fowey, 11 miles SSE. of Bodmin, cures pilchards, and exports 'china-stone' and ores; pop. 2000.

Fowl. See POULTRY.

Fowler, HENRY HARTLEY, Lord Wolverhampton (1830-1911), born at Durham, became a solicitor at Wolverhampton, which in 1880 returned him to parliament. He held a succession of offices in Liberal governments, being President of the Local Government Board, Secretary of State for India, and Chancellor of the Duchy of Lancaster. He was made Viscount Wolverhampton in 1908. See Life by his daughter, Edith H. Fowler (1912).—His elder daughter, ELLEN THORNEY-CROFT FOWLER, who in 1903 became Miss Felkin, made a name by *Isobel Carnaby*, *The Farringtons*, *Kate of Kate Hall* (with her husband), *The Wisdom of Folly*, and other novels.

Fowler, SIR JOHN, born at Sheffield in 1817, became distinguished in railway engineering, river improvement, and the construction of large docks, and on the completion of the Forth Bridge, designed by him and Sir B. Baker, he was made a baronet. He died 20th November 1898. See BRIDGE.

Fowler, THOMAS (1832-1904), philosopher and historian of his college, was born at Burton-Stather in Lincolnshire. He graduated at Merton College, Oxford, in 1854, and was ever after closely connected with that university, first as tutor of Lincoln College, afterwards as professor of Logic from 1873, and as president of Corpus Christi College from 1881. His principal works are *Elements of Deductive Logic* (1867); *Elements of Inductive Logic* (1870); editions of Bacon's *Novum Organum* (1878), and Locke's *Conduct of the Understanding* (1881); *Progressive Morality* (1884); and *Principles of Morals* (1887). Others are Locke in 'English Men of Letters,' Bacon, and *Shaftesbury and Hutcheson* in 'English Philosophers.'

Fowler's Solution. See ARSENIC.

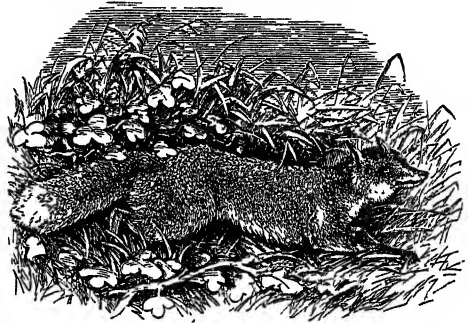

Fowling. See WILD-FOWL.

Fox, the name of a number of species of the family Canidae (q.v.), which are now usually referred to the genus *Canis* (see DOG), but are sometimes regarded as forming a distinct genus, *Vulpes*, distinguished by certain minute differences in the form of the skull and of the teeth, the more elongated body, slender, pointed muzzle, elliptical, somewhat oblique pupil, and bushy tail. Representatives are found in the greater part of the northern hemisphere, but are conspicuously absent from South America.

The following species demand separate notice: (1) The Common Fox (*Canis vulpes*) measures on an average 4 feet in length, of which 16 inches are occupied by the tail; and 14 inches in height; the weight is from 15 to 22 lb. The head is broad, the brow flattened, and the muzzle rapidly tapering, long, and slender; the mouth is furnished with 42 teeth. The body, though apparently thick, owing to its hairy coat, is really lank, but strong and mobile; the legs are slender. The anal glands are strongly developed, giving the animal its well-known odour. The colour above is reddish-brown; the brows, shoulders, and posterior portion of the back, as far as the root of the tail, are shot with white, the hairs in these regions having white tips. The

hair on the lips, cheeks, and throat is white, and a streak of the same colour runs down the legs; the breast and belly are ashy and the flanks whitish gray, the feet red, the ears and toes black, and the tail reddish shot with black, and usually with a white tip. These various tints blend gradually into each other, and produce a *tout ensemble* which renders the animal remarkably inconspicuous.

Sportsmen have an extensive technical vocabulary for all that concerns the fox: the female is a 'vixen,' the young, 'cubs;' his head, a 'mask' or 'pate,' his feet 'pads,' and his tail a 'brush;' his dung is known as 'billet,' and his home is a 'kennel,' or, if underground, an 'earth.'

Common Fox (*Canis vulpes* or *Vulpes alopecus*).

Foxes occupy burrows in the ground, generally utilising those which have been made by badgers, while occasionally they live in company with these animals. These dens are preferably on the sides of hills, the apertures leading downwards and outwards, and consist of a central chamber with several means of exit. When suitable burrows are wanting, hollows under piles of stones, or even hollow trees have been used.

The fox's food embraces a wide range of nutriment, from a fawn or a lamb to beetles, or even vegetables or fruit; nothing comes amiss. Mice form a large percentage of his diet, and when half-sated he will play for long with his food before eating it. He hunts almost exclusively by night, and in his wanderings chooses the most secluded ways and takes advantage of every particle of shelter which the nature of the ground affords when passing from one covert to another. He is fond of warmth, and if undisturbed will bask for long in the sunshine; he runs rapidly and with great endurance, swims well, and has been known to climb trees in the search after eggs. The usual cry is a short bark, most commonly heard at the pairing season; the young ones use their voices freely when hungry. The pairing takes place in February, and the period of gestation is 60-63 days. Before the birth of the young, of which there are usually 4-7, the vixen pulls out the hair from her belly, partly to provide a soft bed for her offspring and partly to expose her nipples ready for their use. When born they are very helpless (both eyes and ears being closed) and covered with smooth brown fur. At six weeks old they appear outside the burrow, and at three months go hunting either alone or with the mother, who tends them with the utmost solicitude, and will face any danger or run any risk in their defence. A vixen has more than once been caught with no more than a mouse in her own stomach carrying home a plentiful supply of larger game to her young.

The fox's mental qualities are of a very high order. His cunning is proverbial, and his knowledge of localities and ability to profit by experience

have been highly developed in an arduous struggle for existence. 'More elegant than his relatives in men and bearing; sharper, more prudent, calculating, and adaptive; of strong memory and sense of locality, resourceful, patient, resolute; equally skilled in jumping, slinking, crawling, and swimming, he seems to unite in himself all the qualifications of a perfect highwayman, and, when his lively humour is also taken into consideration, produces the impression of a highly educated artist in his own line.' When taken very young the fox has been successfully tamed, but he does not exhibit that capability for domestication for which his congener the dog is so remarkable. With this latter, however, he agrees in the parasites by which he is infested and the diseases to which he is liable. Even hydrophobia has been known to attack him, and to have been by him communicated to human beings. He has many enemies; the wolf and dog attack and kill him even when they do not devour; the hawk and eagle take the cubs, and the latter sometimes the adults. His chief foe is man. In northern countries where he is abundant the fox is slaughtered for his fur. The skins are brought from Poland, Russia, and the whole of Siberia. The black variety is much rarer and consequently more valuable than the red.

In Britain the fox has a factitious value as the object of a time-honoured sport, which, though it leads to his being pursued to the death by horse and hound, is still the sole reason why he has not long ago shared the fate of the wolf (see FOXHUNTING). In former days many foxes were dug out of their holes in Germany for the sport of 'tossing.' Long, narrow nets were spread out in front of the holes, the opposite ends of each being held by a lady and gentleman; as soon as reynard in his attempt to escape ran upon the net this was suddenly tightened and the unfortunate creature hurled aloft like a schoolboy in a blanket; and this was repeated until he happened to fall upon solid ground and eluded his tormentors.

Several varieties of the common British form are known to sportsmen; the *Greyhound Fox*, which occurs in the mountainous parts of England and Scotland, is tall, long-limbed, and strong; the *Mastiff Fox* is shorter and stouter, whilst the *Cur Fox* is known by his black-tipped tail. In addition to these several more conspicuous variations have received names and been by some regarded as distinct species. The *Coal Fox* is found in Switzerland and Bavaria, and has a black-tipped tail. The *Cross Fox* is distinguished by a longitudinal dark line down the back and a transverse one over the shoulders. The *Black-bellied Fox* is restricted to the south of Europe, and is sufficiently described by its name.

The *Red Fox* of North America (*C. fulvus*) is very little removed from its European congener: it is not so enduring, but runs with great speed for about 100 yards. For the fur of these three varieties, especially the *Silver Fox* (bred on fox-farms in Prince Edward Island and elsewhere), see FURS.

(2) The *Gray Fox* (*Canis cinereo-argentatus*, *C. virginianus*); sometimes made the type of a distinct genus *Urocyon*) is somewhat smaller than his European relative, and has comparatively longer legs and a shorter tail; the colour is a peculiar speckled gray, due to the hairs being white at the roots and black with white rings in the distal portions. It is abundant in the southern United States, but does not occur north of Maine. It is not so swift as the red fox, but is even more cautious and timid, though its habits are in general similar. It has been seen to stalk game like a pointer.

(3) The *Corsac* or *Steppe Fox* (*Canis corsac*) is the Asiatic representative of the common fox; than this it is decidedly smaller, measuring at most

3 feet in length; it is also somewhat taller, and shorter in the tail, and has a rounder pupil. The colour in summer is reddish, but in winter it becomes paler owing to the development of a white ring round the individual hairs near their extremities. The throat, lower surface of the body, and inner surfaces of the legs are yellowish-white, and there is a three-cornered, dark-gray patch in front of each eye. The tail is dark above, and has a black tip. This species extends from the Caspian Sea to Mongolia, wherever there are extensive steppes, but it never occurs in forests or mountains. Its habits are like those of the European form. It is eagerly pursued by the Kirghiz and Turcomans for the sake of its fur: all the ordinary means are employed for its capture, and in addition eagles are trained to hunt it, and it is forcibly dragged from its earth by an apparatus resembling a magnified corkscrew. As many as 50,000 skins are said to have come into the market in some years.

(4) The *South African Desert Fox* (*Canis chama*) is only about half the size of the European fox, and is said to live almost entirely on ostrich eggs, which it rolls from the nest to its burrow and then breaks against a stone.

(5) The *Fennec* (*Canis zerda* or *F. cerdo*) is a delicately-formed little creature, remarkable for its large eyes and enormous ears, which have led some authorities to place it in a special genus (*Megalotis*). It is found in the deserts of northern Africa and the adjoining parts of Asia, and lives in burrows in the ground, usually near the roots of shrubs. Unlike the common fox it excavates its own home, and is able to dig so rapidly that it can often hide in this manner when pursued. Small birds are its favourite food, but it will also eat lizards, beetles, and grasshoppers, or even vegetable products such as dates or melons: fennecs have been supposed by some to be 'the little foxes that spoil the vines' of Scripture. They produce three or four young ones at a birth, which are tenderly cared for by the mother. When taken young they soon become very tame; they are captured by snares fastened at the entrance of their burrows, and, strange to say, they make no attempt to bite the nooses, though they struggle hard to break them.

(6) The *Arctic Fox* (*Canis lagopus*) is very well characterised by its short, blunt snout, rounded ears, short legs, and hairy covering to the soles of the feet, whence the specific name. The summer coat is brownish or gray above and on the sides, and white below; but as winter approaches the colour of the whole becomes pure white, although individuals are occasionally observed which have not changed their hue. The species is distributed over the polar regions of both the Old and New Worlds, as well on islands as on continents: it only wanders exceptionally south of the 60th parallel of latitude. The cubs are born in the latter half of June, the vixen choosing a cleft in the rock or some similar position for her nursery. Its food consists of any animals which it is strong enough to overpower, especially mice and lemmings; but in case of need it will eat creatures of any kind that may be cast up by the sea, and will even venture into the huts of the Eskimo and steal whatever it can carry away, whether edible or no. When food is abundant it will conceal it and return to its store in time of need. In character it presents a curious mixture of cunning and of impudence. Steller records that during his stay on Behring Island the foxes would come and try to take the meat from the hands of himself and his comrades, gnaw their boots, or sniff around their faces as they lay asleep; and also that in spite of numbers being slain they did not become shy. That this was not entirely due to lack of acquaintance with human beings is shown by their exhibiting the same characteristics in

Norway. When young they can be easily tamed, and as pets have the advantage of being free from the disagreeable odour associated with most foxes. The fur is a marketable article, though not so valuable as that of some of the other species. See FOXHUNTING, FURS.

FOX, CHARLES JAMES, Whig statesman, was a son of Henry Fox, first Lord Holland, by Lady Georgiana Carolina, eldest daughter of the Duke of Richmond. He was born on the 24th January 1749, and was educated at Eton and Oxford, spending part of his vacations on the Continent in the gayest and wittiest circles of the French capital, and visiting Switzerland and Italy. Notwithstanding the irregular life which he led even as a schoolboy, he was very distinguished for ability both at school and college; and so high was his father's opinion of his talents that at the age of nineteen he had him brought into parliament as member for the borough of Midhurst, a step to which he is said to have been further incited by the fact that, even at this early age, Fox's energies had found an outlet in gambling and other forms of dissipation. His precocity in vice, as well as in intellectual development, is said to have been the result of the injudicious fondness of his very unprincipled but very gifted father. Till he attained his majority Fox prudently kept silent in the House, but immediately thereafter he appeared as a supporter of the administration of Lord North, and was rewarded with the office of one of the lords of the Admiralty. In 1772 he resigned that office owing to a difference with Lord North, but the following year was named a commissioner of the Treasury. From that post he was dismissed two years afterwards, in consequence of another quarrel with Lord North, and passed over to the ranks of the opposition. During the whole course of the American war he was the most formidable opponent of the coercive measures which were adopted by the government, and the most powerful advocate of the claims of the colonists; acting, to this extent at least, in accordance with the views which for many years before had been urged upon the country by the great Lord Chatham. The difference between them was that, whereas Lord Chatham urged conciliation in order to preserve the connection between the two countries, Fox foresaw and foretold the necessity and the advantages of complete separation.

In 1782, on the downfall of Lord North, Fox was appointed one of the secretaries of state, which office he held till the death of the Marquis of Rockingham. On the dissolution of the Shelburne administration in 1783 the North and Fox coalition was formed, and Fox resumed his former office; but the rejection of his India Bill by the House of Lords soon after led to the resignation of his government. It was now that Pitt came into power, and that the long and famous contest between him and Fox, who occupied the position of leader of the opposition, commenced. In 1788 Fox enjoyed a short respite from his public labours. Accompanied by his wife, he visited the Continent, and after spending a few days at Lausanne in the company of Gibbon, who was there engaged in writing his famous history, he set out for Italy. The sudden illness of the king, however, and the necessity of constituting a regency rendered it undesirable that he should be longer absent from England, and he hastened back to his post. The regency, the trial of Warren Hastings, the French Revolution, and the events which followed it gave ample scope to the talents and energies of Fox, and on all occasions he employed his influence to modify, if not to counteract, the policy of his great rival. He was a strenuous opponent of the war with France, and an advocate of those non-intervention views which find greater favour in our day than they did in his.

After the death of Pitt in January 1806, Fox was recalled to office, and endeavoured to realise his doctrines by setting on foot negotiations for a peace with France, the results of which he did not live to witness. He was on the point of introducing a bill for the abolition of the slave-trade, when he died at Chiswick, on the 13th September 1806, in his fifty-eighth year. In private life Fox was a genial companion; towards his opponents he was generous, and free from malignity or enmity; but critics like Mr Fortescue (in *British Statesmen of the Great War*, 1911) insist that he was early demoralised by self-indulgence, reckless of the interests of others as of his own, and not a little selfish. Of his oratorical powers it is enough to record that Burke called him 'the greatest debater the world ever saw,' and Sir James Mackintosh, 'the most Demosthenian speaker since Demosthenes.' His remains were interred in Westminster Abbey, near to those of Pitt.

See the *Life and Times* and *Memorials and Correspondence*, by Earl Russell; the *Character*, by Dr Parr (1809); the *Early History*, *The American Revolution*, and *George III. and Fox*, by Sir George Trevelyan (1880-1914); and the *Lives* by Wakeman (1890) and Hammond (1903).

FOX, GEORGE, the founder of the Society of Friends (q.v.), commonly called Quakers, was born in July 1624, at Fenny Drayton in the south of Leicestershire. His father, a woollen-weaver, apprenticed him at an early age to a man who combined the trades of shoemaking, wool-dealing, and farming. With him George was principally employed in tending sheep—an occupation which suited his meditative disposition. When about nineteen years of age his religious convictions deepened to such an extent as to make him believe he was the subject of a special divine call to leave his native place and his friends, 'to forsake all, young and old, to keep out of the way of all, and to be a stranger to all.' Bible in hand, he wandered about the country, spending even his nights in the open air, a small competency he had supplying his slender wants. From his clothing he became known as 'the man in the leather breeches.' He soon began to attend meetings, and often to interrupt divine services, especially when these were conducted by 'professors,' persons whom he believed to be formalists and not genuine Christians, and when held in 'steeple-houses' and called together by church-bells, to which he had a special antipathy. The church he held to be the pillar and ground of truth, made up of living stones and lively members, a spiritual house of which Christ is the head. He was not, he said, the head of a mixed multitude, or of an old house composed of lime, stone, and wood. The 'inward light,' in which all orthodox Christians now believe, though to him it seemed a special revelation which he afterwards found in the Scriptures, was the central idea of his teaching. He was not only a great religious, but a great social reformer. As the former he inveighed against everything approaching to sacerdotalism and formalism. As the latter he ran a tilt against all social conventionalism. Not only priests, but lawyers and soldiers, were obnoxious to him as the embodiment of principles which he hated. Everywhere he went he was a marked man: his dress, his mode of speech, his manners, were different from those of others. 'The Lord' forbade him 'to put off his hat to any, high or low,' and 'he was required to *thee* and *thou* all men and women, without any respect to rich or poor, high or low, great or small. And as he travelled up and down, he was not to bid people *good morning* or *good evening*, neither might he bow or scrape with his leg to any one.' He saw the evils of intemperance, and denounced all public

amusements. He thus came into collision with all sorts of people, and his life is indeed little else than a record of insults, persecutions, and imprisonments, to which his zeal and indiscretions subjected him. His experiences of prison were numerous, and of such a nature as to make him one of the earlier of prison reformers. Arrested on one occasion by Colonel Hacker, he was taken to London to be examined by the Protector, who became convinced of his sincerity and of the harmlessness of his tenets. This, however, did not prevent the continued persecution of himself and his followers, who in 1656, the year after they refused to take the oath of abjuration, had increased to such an extent that there were nearly one thousand of them in gaol. He visited Wales and Scotland, and after his marriage to the widow of Judge Fell he went to Barbadoes, Jamaica, America, Holland, and various parts of Germany. In these later wanderings he was accompanied by Penn, Barclay, Keith, and others of the more eminent of the second generation of Quaker ministers. He died 13th January 1691. Amongst his last words were, 'All is well. The seed of God reigns over all, and even over death itself.' Full of personal peculiarities, guilty of many indiscretions, he was yet an amiable and Christ-like man, with a heart full of love for his fellows, and a mind so capable and comprehensive as to enable him to institute the admirable systems of registration, poor relief, education, and self-help, which have made the sect he founded a real social power. His preaching and writings were often turgid, incoherent, and mystical. As a writer he will be always remembered by his *Journal*, full of heart and intellect, valuable as giving with extreme simplicity and an unflinching regard for truth a record of his own life, and of the manners and customs, especially of the poorer classes, in the stormy times in which he lived.

The *Journal* was not edited direct from his MS. till 1911 (by Norman Penney), earlier editions being subjected to official modifications. His works were collected in 3 vols (1694-1706); in 1852 an edition in 8 vols. was published at Philadelphia. The list of his writings in Smith's *Catalogue of Friends' Books* (1868) occupies 53 pages. See Sewall, *History of the Quakers*, Cunningham, *The Quakers*; Neal, *Puritans*; Marsh, *Life of Fox* (1848); Lives by Janney (1853), J. S. Watson (1860), Hodgkin (1896); Bickley, *Fox and the Early Quakers* (1884); Deacon, *Fox and the Quaker Testimony* (1896).

FOX, WILLIAM JOHNSON (1786-1864), orator and political writer, was born near Southwold, Suffolk, the son of a small farmer, who afterwards settled as a weaver at Norwich. Sent to Homerton College to be trained for the Independent ministry, he subsequently seceded to Unitarianism, and ultimately delivered a series of prelections at his chapel in South Place, Finsbury, which marked him out as the leader of English rationalism. When the Anti-corn-law League enlisted the ablest platform orators of the day in the service of free trade, his bold and impassioned rhetoric greatly contributed to arouse and intensify public feeling. M. Guizot quotes his speeches as the most finished examples of oratory which the great conflict produced. Their effect upon the vast metropolitan audiences to which they were addressed was electric. Fox also contributed by his pen to the success of free trade, and his *Letters of a Norwich Weaver Boy* were largely quoted and read. From 1847 till 1863 he sat as an advanced Liberal for Oldham in parliament, where his success was hardly equal to the oratorical promise of his platform and pulpit career. His best parliamentary speeches were upon the education of the people. One of the earliest contributors to the *Westminster Review*, he edited for many years the *Monthly Repository*, and published many lectures, &c., col-

lected in the Memorial Edition of his works (12 vols. 1865-68). See Life by R. and E. Garnett (1910).

Fox Channel, the northern portion of Hudson Bay, washing the western shores of Baffin Land, takes its name from Luke Fox, an English navigator, who was born about 1583, explored Hudson Bay in 1631, and died subsequent to 1635.

Foxe, JOHN, the martyrologist, was born of respectable parents in 1516, at Boston, in Lincolnshire. At sixteen a fellow of Brasenose College brought him to Oxford, apparently as a private pupil. He seems to have attended Magdalen College School, and to have become an undergraduate of Magdalen College. He took his bachelor's degree in 1537, his master's in 1543, and was elected a fellow of Magdalen in 1538. He had already acquired a reputation by his Latin verses, but soon gave himself to the study of the Fathers, and of the theology of the Reformers, with the result that he found his position among less advanced colleagues at Magdalen irksome, and voluntarily resigned his fellowship in 1545. For some time he was employed as tutor to the children of William Lucy of Charlecote, Warwickshire; there he married early in 1547, and afterwards was engaged by the Duchess of Richmond as tutor to the children of her brother, the Earl of Surrey, who had been executed, 19th January 1547. During the reign of Mary, for safety's sake he retired to the Continent, and at Strasburg, Frankfurt, or Basel met all the leading Reformers, including Knox, Grindal, and Whittingham. At Basel he was employed as reader for the press in the printing-office of Oporinus. He returned on the accession of Elizabeth, was pensioned by his old pupil, now Duke of Norfolk, and received, in May 1563, a prebend in the cathedral of Salisbury. He lived chiefly in Cripplegate, London, and often preached. For a year he held a stall at Durham. But he was prevented from further preferment by his conscientious objection to wearing the surplice and other practices of the establishment. To his credit it must be said that he pleaded for religious toleration when some Dutch Anabaptists were condemned to the flames in London in 1575. He interceded for them with Queen Elizabeth and other persons in authority, but without effect. He died in 1587, and was buried in London, in the chancel of St Giles's, Cripplegate. Foxe published numerous controversial treatises and sermons, besides an apocalyptic Latin mystery play, called *Christus Triumphans* (Basel, 1556). But the work that has immortalised his name is his *History of the Acts and Monuments of the Church*, popularly known as *Foxe's Book of Martyrs*, the first part of which was published in Latin, in an octavo volume, at Strasburg in 1554, reprinted along with five other books at Basel in a folio volume in 1559. The first English edition appeared in 1563, in one volume folio. Sanctioned by the bishops, it was ordered by a canon of the Anglican Convocation meeting in 1571 to be placed in the hall of every episcopal palace in England; and it went through four editions in Foxe's lifetime, and numerous others since his death. Apart altogether from the vexed question of its historical value, it will survive as a noble monument of English. Foxe's statements cannot be accepted as trustworthy evidence, if unsupported from other sources. His story is doubtless substantially true, although his credulity and bitter prejudice hardly suggest critical capacity in the selection of his authorities.

He was warmly commended by Strype (who came into possession of Foxe's MSS.), Whitgift, Camden, Burnet, and Thomas Fuller. Apart from

Roman Catholic critics, many of whose attacks are justifiable, Foxe's exaggerations and want of historical precision have been best exposed by the Rev. Dr S. R. Maitland, in a series of pamphlets issued between 1837 and 1842. The biography of Foxe, attributed to his son Samuel, and published in both Latin and English in the 1641 edition of the *Acts*, is certainly apocryphal, although it has formed the basis of numerous popular memoirs.

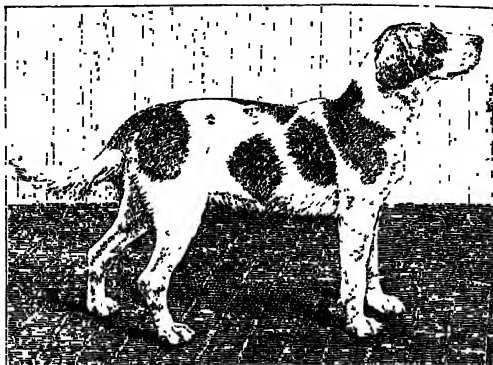

The best edition is that in the 'Reformation' series of the Ecclesiastical Historians of England, edited by R. R. Mendham and Josiah Pratt (8 vols. 1853 *et seq.*), with Canon Townsend's vindication against the attacks of Roman Catholics.

Foxglove, a species of *Digitalis* (q.v.). The Common Foxglove (*D. purpurea*) is a native of Britain, and a familiar and conspicuous ornament in woods and hedgerows, its flowering stem reaching a height of from 2 to 4 feet, or even more. It flowers from June to August. Both it and its white-flowered variety are frequently planted in gardens and shrubberies. Its English name, the German name Fingerhut ('thimble'), and the botanical name *Digitalis* (Lat. *digitale*, 'the finger of a glove') refer to the form of its flowers. The foxglove was a favourite with the fairies, and was called in Ireland Fairy-cap, and in Wales Elf-glove, elsewhere Fairy-fingers, Fairy-petticoats. But there seems no good ground for the attempt to make out that foxglove is a corruption of Folk's-glove, for Good-folk's Glove, or Fairy-glove. Another English provincial name is Fox-fingers.

Common Foxglove
(*Digitalis purpurea*).

probably a cross between the old southern hound and the greyhound, combines the nose and tongue of the former with the speed of the latter. When the large woods began to disappear, and more 'blood' was used in our hunters, the pace of the hound was found to be still too slow. The foxhound continued to be bred for speed, until now we have a hound possessing a dash wholly unknown to the original foxhound, and capable of getting away from a large field of horses. The head of the foxhound should be large, deep through the muzzle, but without throatiness or heaviness; teeth, strong and even; shoulders, oblique and muscular; back, short and strong; legs, with great bone perfectly straight in front; hocks, well let down behind; feet, round with arched toes; ears, naturally long and graceful, but always 'rounded' or shortened to prevent tearing when working in coverts; colour, white, with black or tan markings, sometimes to a great extent; height, 22 to 24 inches. In addition to the necessary amount of speed the foxhound must

possess staying powers of a high order, a good nose, and be without a tendency to 'babble' or 'run mute'—i.e. to give tongue when not on a scent, or the opposite fault, to refuse to speak to a scent.

Foxhound.

In breeding a pack of foxhounds the individual hound must not be considered, but the speed of the whole pack must be increased or reduced as necessity demands, so as to have the whole pack hunting together. Foxhounds (not bloodhounds) were till of late regularly trained—and used—to track escaped convicts at the great southern convict camps in the United States; hounds a little larger and slower than English hunting foxhounds.

Foxhunting. That foxhunting has been carried on in England for at least six hundred years is proved by a certain amount of evidence gathered from old deeds and documents. But for the first two-thirds of this period it is quite certain that the fox was only hunted to be killed, and that pursuing him in the interests of sport was quite unknown. The fox was indeed, throughout the middle ages, regarded as vermin, and was hunted for extermination, being driven into nets or dug out of the ground. Though there were many breeds of hounds in almost every part of the kingdom, none of them were then regarded as foxhounds, and practically all were kept for the chase of the wild deer and the hare. As far as is known, the earliest Anglo-Norman writing which has hunting for its subject was written by one Guillaume Twici previous to 1327, and this, though it treated of stag-hunting, hare-hunting, hawking, fishing, and other sports, made no mention of the fox as an animal who was worthy of being hunted. On the other hand, there are records of permission to hunt the fox, notably one granted by Richard II. to the Abbot of Peterborough, and another by Henry IV. to Henry de Popham, 'for taking hares and foxes in the County of Southampton.' It is sometimes asked why foxhunting, which, for at least one hundred and fifty years, has been the greatest of all English field-sports, was not practised at an earlier date than the records show, and the answer is fairly obvious, viz. that the country generally was physically unfit for what has been long known as cross-country riding. During the middle ages, and through a much later period, the land was very partially cultivated, and was covered with forests, chases, and wide open heaths or commons, all of which were strictly preserved for the chase of the stag or buck. Stag-hunting, hawking, and coursing were the sports which were followed by equestrians, and the horses used were slower and heavier than the modern hunter, and almost certainly asked to carry more weight, both in saddle and equipment. Indeed, the saddle of the

16th century appears to have been nearly three times the weight of the modern hunting saddle, and the horses were just as frequently required to carry men in armour as to follow the chase. During the later Stuart period there was an extraordinary and very rapid improvement in the breed of horses, owing to the importation of a vast number of Eastern sires. These were Arabs, Barbs, and Turkish horses, and so thoroughly were they distributed about the country, that in a few years the light horse, as distinguished from the horse used for war, became the popular breed of the day, at a time when every one rode from place to place on business or in pursuit of pleasure, as the case might be. During the 17th and 18th centuries land was being reclaimed in almost every part of the country, and hundreds of thousands of acres of forest disappeared. The stag and the buck were also being quickly brought down in numbers, and owners of hounds were in many districts obliged to find some other quarry to hunt. It was, too, discovered some two hundred years ago that horses could travel faster than their ancestors of only two or three generations before, and that the country was gradually becoming more rideable. But who first conceived the idea of hunting the fox in the manner he has been hunted for the last two hundred years is absolutely unknown; and though there are many hunts which claim to be the oldest in the kingdom, several of these began as stag or hare hunts, and no actual date as to when they changed to fox is forthcoming.

'The Diuid' in *Silk and Scarlet* states that prior to 1750 it was sound orthodoxy to hunt what came first to hand, and that it was not until some twenty years later that the line of demarcation between hare and fox began to grow sharp and clear. That many of the earlier packs hunted hares in the autumn and foxes after the turn of the year is well known, and there are at the present day old harrier packs who still turn their attention to foxes in the spring of the year. Certain it is that all the great family packs which were in existence during the first half of the 18th century had become foxhounds at some period before 1800; but in remote provincial countries the change came even later, and there are at the present day certain long-established hunts which were harriers about 1850, or even a little later. It being impossible to say definitely which is, or was, the oldest pack of foxhounds, mention may be made of some of the older packs about which definite facts are known. The Charlton Hunt went back—it no longer exists—to 1689, when, according to *Sussex Archaeological Collections*, a Kentish gentleman named Roper managed a pack of hounds for the Duke of Monmouth and Earl Grey. It has always been understood locally that this pack was maintained to hunt the fox alone, but the records as to its earliest hunting are vague, and the claim with regard to foxes is mostly traditional. The country of the Charlton Hunt was hunted some years ago by the Duke of Richmond, but more recently it has formed part of Lord Leonfield's big Sussex country. Another hunt can show even stronger evidence that it has always been a fox hunt, and was not formed from a harrier pack. The hunt in question is the Quorn, one of the most important hunts in the kingdom. The evidence as to the fact that foxes were the only quarry of the Quorn Hunt is afforded by a hunting-horn which bears the following inscription: 'Thos Boothby Esq., Tooley Park, Leicester. With this horn he hunted the first pack of foxhounds then in England 55 years. Born 1677, died 1752.' The year 1698 is given by some authorities as the commencement of Mr Boothby's long mastership, and this would make his hunting

period fifty-four years, presuming that he was still hunting the country at the time of his death. It should be added that in Mr Boothby's time the hunt was a private pack, and not known as the Quorn; but Mr Hugo Meynell, who followed Mr Boothby, hunting much the same country, has always been regarded as master of the Quorn. Two Yorkshire hunts can also claim great antiquity, viz. the Sinnington and the Bilsdale, but in all probability their origin is identical, both being within the district hunted by the Duke of Buckingham in '1680 or thereabouts.' The Sinnington is nearer to what used to be the Forest of Pickering, which was generally supposed to be the duke's favourite hunting ground; while in Bilsdale there is a spot known as Buckingham Stone, where tradition has it that a horse of the duke's died after a great run. Some years ago the author of a book which dealt with hunting in Dorsetshire stated that the Cranborne Chase Hunt had the distinction of being the first country in which hounds were kept to hunt fox to the exclusion of other quarry; but older authorities give the date of the establishing of this pack as 1730, which puts it many years behind the Charlton Hunt and the Quorn. As to what quarry was hunted by the Duke of Buckingham nothing can be stated with certainty, but probably bucks were hunted before the country was disafforested in the reign of Charles I, and whether foxes or hares took their place when the deer disappeared is a matter of doubt. What may be taken as certain is, that packs of hounds have been maintained in England for at least six hundred years; that for the first four of these six centuries stags or bucks were the chief quarry, though hares were hunted as well; that the early part of the 18th century was a period of transition from stag and hare to fox, and that this transition was continued for another seventy or eighty years, until the country as a whole became much what it is at the present day as regards the geographical arrangement of packs.

It should be explained, however, that the number of hunting countries has been greatly increased in quite modern times, and this increase is due to various counties having been divided, and even subdivided, so that they could be more thoroughly dealt with, or, in other words, that hounds could hunt all parts of their country regularly instead of going once or twice in a season to the outside districts, and neglecting the less desirable places altogether. In the early days of foxhunting all the packs were privately owned, and without doubt there were no very definite boundaries of country. It is said, for example, that the Berkeley country was so large as to extend from London to the estuary of the Severn, and this is confirmed by the fact that at the present day there is the Old Berkeley Hunt, in Herts, Bucks, and Middlesex, with kennels near Amersham, and the Berkeley (the Earl of Berkeley's) in Gloucestershire. The Berkeley Hunt dates from 1613; but there is nothing to show that it was a foxhunt, or even that foxes were ever hunted by this pack in its early days. The late Granville Berkeley, however, wrote of his father, the 5th Earl of Berkeley, about 1859—that he (the 5th Earl) used to hunt all the country from Kensington Gardens to Berkeley Castle and Bristol (a distance of over a hundred miles in a straight line). His nearest covert to London was Scratch Wood, near Wormwood Scrubs, and from that covert hounds ran to Kensington Gardens about the beginning of the 19th century. The Earl of Berkeley had kennels at Cranford (Middlesex), Nettlebed, in Oxfordshire, and possibly at other places between the two extremities of the hunt; but it is not definitely decided that the pack (or packs) hunted much in the middle of the huge

district involved, and it is certain that nearly all through the 18th century the hounds of the various Dukes of Beaufort were hunting in Wilts and eastern Gloucestershire large tracts of country which are in the direct line between Cranford and Berkeley Castle. One writer has suggested that separate hunting establishments were maintained at either end of the hundred miles—that is to say, at Cranford and Berkeley Castle—and that when the Earls of Berkeley travelled between Berkeley Castle and London they took hounds with them, and hunted when opportunity offered.

To mention a few of the older and more important packs, the Belvoir, the Brocklesby, and the Badminton (the Duke of Beaufort's) rather stand out, chiefly because they are still holding their own as three of the greatest hunts in the kingdom, and also because of the blood in their kennels being of extreme value. Indeed, Belvoir blood is a byword in hound lore, and has permeated into every modern pack in the kingdom; and it has been built up in a great measure from Brocklesby blood, and freely crossed at times with the blood of the Badminton kennel. The Brocklesby claims to date from 1700, or even a little earlier, and its hound list goes back to 1746. The Belvoir Hunt dates from 1750, and has hunted foxes exclusively since 1762. The first named of the two packs has always been owned by the Pelham (Lord Yarborough's) family, while the Belvoir hounds have always belonged to the reigning Duke of Rutland, though at times certain other gentlemen have been masters of the pack. Which of the Dukes of Beaufort first formed the Badminton pack is not clear, but it is said that there were always hounds at Badminton, and only foxes have been hunted since about 1770 in all these countries. The Southwold, in Lincolnshire, was formerly part of the Brocklesby country; while the adjoining Burton country dates back to 1774, when the third Lord Monson was master. The Blankney was taken out of the Burton country in 1871. The date of the Quorn Hunt has been given. The popular Fernie Hunt was a part of the Quorn country until 1853. The Cottesmore, which borders the Fernie and the Quorn, and is thought by many experts to contain much of the best riding country in the kingdom, is an old pack, the country having been hunted by the Noel family about 1730. Indeed, one Thomas Noel was responsible for a *Book of Hounds*, which is dated 1732, and the Noel family had the pack until 1788. Since then the Lowther family has provided many masters of the pack. The Pytchley dates from about 1750, and in 1782 the Pytchley Hunt Club was a flourishing institution, with a membership of twenty-eight. The Warwickshire is an old country, but its early history is a trifle vague, though Mr Corbet was hunting part of it in 1778, and Mr Wrightson another part two years later. As at present constituted the country dates from 1812, and the North Warwickshire—which Mr Corbet had hunted nearly fifty years before—from 1838. The Atherstone dates from 1804, and the Meynell from 1816, while the Bicester country was hunted by Mr John Warde towards the close of the 18th century, and by Sir Thomas Mostyn in 1800, since which date it has been known under its present name. All the above are important Midland packs. The countries of the Quorn, the Fernie, the Cottesmore, the Belvoir, and the Pytchley are what are frequently termed 'the shires,' and as regards grass to gallop over these are generally acknowledged to be the best riding countries in the kingdom—though the Tynedale, in Northumberland, is emphatically a grass country, and its neighbour, the Morpeth, almost equally so. There are grass countries in Ireland also, and much grass

in the Warwickshire, Bicester, Atherstone, North Warwickshire, Meynell, and other countries which are not far away from the 'shires.'

There are many other countries besides those just mentioned which take high rank, and yet are not quite grass countries when compared to those of the 'shires.' Foremost among them is the Duke of Beaufort's country, the largest and most varied of any country in the kingdom. Here there are grass vales, a high-lying plateau where grass and light plough-land are in fairly equal proportions, certain hilly districts, and a good deal of woodland. Every kind of fence is to be found in the many vales of the Badminton Hunt, and stone walls on the high land. There is, in fact, great variety of country from a hunting point of view, and while the best of it is excellent, none of it is bad. To the south of the Duke of Beaufort's country lie the two divisions of the Vale of White Horse, which were formerly, together with the Old Berkshire, one single and very large hunt. The original hunt, which included the South Oxfordshire as well as the Old Berkshire and the Vale of White Horse, goes back to 1760; the Old Berkshire was taken from it in 1830, and a year later the V. W. H., which was for a season the western end of the Old Berkshire, was established, while the South Oxfordshire became a separate hunt in 1845. Both the V. W. H. and the Old Berkshire are important and very good countries; and a similar remark applies to the Avon Vale, which is for the most part in the Duke of Beaufort's original country, while some of it belongs to the South and West Wilts Hunt, and is loaned by them. Another old country is the Craven, which dates back to the Lord Craven of 1739, but has been a subscription pack for more than a hundred years; while its neighbour, the Vine, dates from 1770, and has a complete list of masters from 1790. The H. H., or Hampshire Hunt, was established about 1745, but for forty years the hounds were staghounds, and only made fox their quarry in 1791. The Gath Hunt had Sir John Cope for master more than a hundred years ago; and the Old Surrey, now joined to the more modern Burstow, has a life of over a hundred years; and the same can be said of the Surrey Union pack. The Tickham is another old pack. The East Kent dates from 1814, while the West Kent country was hunted by Mr John Warde of Squerries in 1776, since which time the country has always been hunted. The Essex Hunt was founded in 1785, the East Essex in 1820, and the Essex Union two years later; while the Puckeridge became a separate hunt in 1799, it and the Hertfordshire having been previously one hunt. These Essex and Hertfordshire packs hunt what are generally considered to be the best plough countries in the kingdom, and all draw largely upon Londoners for their subscribers—not that many people actually hunt from London in these days, but, nevertheless, all the hunts within something like a fifty-mile radius of London are to a great extent supported by professional and business Londoners who have made their residence in the country of their choice. The Cambridgeshire, in which there is as much, or perhaps more, plough than grass, was established in its present state in 1827; but a more important hunt lies north of it, this being the Fitzwilliam, often spoken of as the 'Milton,' because the kennels are at Milton Park, the residence of Mr George Fitzwilliam, who has been master, or joint-master, of the pack, except for two short intervals, since 1887. There are two other packs in the Fitzwilliam family, known as Lord Fitzwilliam's (Grove) Hunt in Notts, and Lord Fitzwilliam's (Wentworth) Hunt in South Yorkshire. The Milton pack is, however, the parent pack, and the hounds have been famous

for many generations, and the blood widely diffused through the country. The hound pedigree book of the Milton pack goes back to 1760, and it is known that an earlier book was destroyed by fire. Of the Yorkshire Hunts the Sinnington (which is mostly a grass country) has been mentioned, as also the Bilsdale. The Badsworth dates from 1730, and the Holderness from 1726. The Middleton Hunt began in 1764, and the Braitham Moor pack, of which Viscount Lascelles became master in 1922, have been in the possession of the Lane-Fox family since about 1750, while the list of masters of the York and Ainsty goes back over a hundred years. The Bedale country, as it now is, dates from 1832; but the country was hunted long before, and was, in fact, part of Lord Darlington's great country, which more than a hundred years ago extended from Sundeland Bridge, four miles south of the city of Durham, to Boroughbridge in Yorkshire. Out of this hunt came parts of the South Durham, and all of the Zetland and the Bedale. The list of dates could be extended, but the oldest and most important hunts have been mentioned, so that a general idea of the age of foxhunting can be formed. It has been shown that numerous divisions of country have been made, with the result that every part of the kingdom where hunting is possible is utilised for the purpose. Even among the mountains of the Lake District there are five packs of hounds, which are followed on foot; and there is hunting all over Wales, horses being used almost everywhere, for much of the Welsh mountain district is rideable, and in nearly all the hunts there is vale land as well as hilly country. In England the Midlands are for the most part flat, and here are most of the best countries. Farther north, in many parts of Yorkshire, Northumberland, and Durham, capital hunting countries are to be found; and Cheshire is also a good hunting country, owing to the fact that its surface is largely covered by dairy-farms. The plough countries lie chiefly in the south-east of England—in Essex, Herts, Bedford, Cambridge, Norfolk, and Suffolk; while Surrey and Sussex are for the most part hilly, with many great woodland districts. Hampshire is much more open, except in and about the New Forest—where there are foxhounds and buckhounds as well—and Dorset is the best of the southern countries from a hunting point of view, with four famous packs, the Blackmore Vale, the Cattistock, the Portman (formerly Lord Portman's), and the South Dorset to wit. In Devon there are a great number of small establishments, and every inch of the country is hunted, but the various countries are for the most part hilly, and the following almost entirely local.

As regards the *modus operandi* of hunting, the best methods were adopted more than a hundred years ago, and have hardly been changed. Time was when meets took place at a much earlier hour, very frequently at daybreak, but that was because the sportsmen of that day liked their hounds to find the drag of a fox and hunt it until they found the fox himself. Foxes in those days were much scarcer than they are now, when the time of meeting is usually from 10-30 to 11 A.M., and even later when the spring is advancing. During the cub-hunting period of the early autumn the early meet still takes place; but the reason for this is that, at daybreak in September, for example, the ground is much moister owing to dew than it is a few hours later, and this moisture enables hounds to work better than when the surface has been dried by a hot sun. From the meet hounds are taken to some woodland or gorse covert, into which they are sent, and which they go through in quest of a fox. If the fox leaves the covert hounds follow him, and run him by scent until one of three things occurs:

they kill him, they run him to ground—which means that he gets into a hole, a drain-pipe or conduit, or a rocky place where hounds cannot follow—or they lose the scent and cannot follow any longer. If the fox will not leave the covert in which he is found he is either killed, or lost, or goes to ground as he would do in the open; he possibly finds a substitute in the shape of another fox, when he immediately lies down, allowing the other fox to go on in front of hounds. The 'field,' by which is meant those who follow hounds on horseback, will be outside the covert if it is a small one, but if a big woodland is drawn they will probably be allowed to follow on behind hounds as they draw, and should be able to see a good deal of woodland hunting. When a fox leaves the covert no one should move until hounds have come out, found the scent, and gone away in advance of the riders. The latter then follow as best they can, regulating their pace according to the pace at which hounds are going in front. The pace varies according to the scent. If scent is really good, horses have to gallop their hardest to keep near hounds. If scent is poor, and hounds have to seek for it all the way, then the field must go slowly, and on no account get too near the pack. Hounds must be allowed plenty of room in which to hunt on a moderate scent, and no rider except the huntsman should at such times go within at least a hundred yards of the pack. The huntsman who carries the horn is in charge of the pack, and he is the only man who is allowed to interfere with hounds in the course of a hunt. He may cast them forward, or to one side when they have lost touch of the scent. He may lift them on to what appears to be better scenting ground—out of plough-land on to grass, for example—and he may stop them altogether if he thinks that it is no longer worth while to persevere. His actions should be watched and noted by those who do not really understand hunting, but, like 'the man at the wheel,' he should never be spoken to while he is undertaking the most difficult part of all his duties, viz. trying to get his hounds to maintain the line of a fox when scent is almost non-existent. When one fox is accounted for by being killed, put to ground or lost, hounds are taken to another covert, and there is a repetition of the draw, find, and hunt, but at times many coverts—at all times of the day—are drawn and no fox found therein. Foxes live for the most part underground, but during the night, while they are out in quest of food, the holes which they are known to use are stopped, so that the foxes are outside, generally in covert, when hounds come to look for them. The holes, or 'earthis' as they are always called, are opened again in the afternoon when the sport is at an end. Gamekeepers are usually paid so much a head for each fox hunted from their beat, and the amount varies according to the custom of the district, but is never less than 10s. Foxhunting begins in most countries in September, and cub-hunting continues until the end of October. The regular season opens on or about the 1st of November, and terminates at the end of March, though many packs extend their meets for a week or two of April if the season is not a very early one.

See *Thoughts on Hunting*, by Peter Beckford; Radcliffe's *Noble Science*; Vyners' *Notitia Venatica*; Cook's *on Foxhunting*; the *Complete Foxhunter*, by Charles Richardson (1906); *Hunting the Fox*, by Lord Willoughby de Broke (1921).

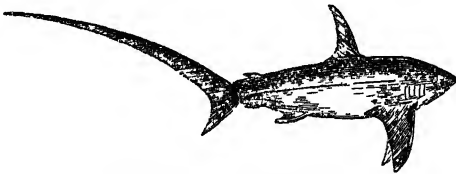

Fox Indians, an Algonquin tribe, whose warriors sided alternately with the French and English in the wars of the 18th century, and in that of 1812-14 were allies of the English. A number now farm lands acquired by purchase in Iowa; but most of the tribe were settled, with

the kindred Sacs, on a reservation between the Canadian and Arkansas rivers.

Fox Islands. See ALEUTIAN ISLANDS.

Fox River, the name of two streams rising in Wisconsin. (1) The Fox River, or Pishitaka (220 miles), flows south to Aurora, then south-west to the Illinois, which it enters at Ottawa.—(2) The Fox River, or Neenah, after a tortuous but generally north-east course of about 250 miles, falls into Green Bay in Lake Michigan. It is divided into two sections by Lake Winnebago, the upper one being connected by a canal with the Wisconsin, so as to link together the Mississippi and the Great Lakes.

Fox-shark, or THRESHER (*Alopias vulpes*), the commonest of the larger sharks occasionally seen off British coasts. It is the only species of its genus, and is widely distributed in the Atlantic and Mediterranean, also occurring off California and New Zealand. It is much smaller than the basking shark (*Selache maxima*), but attains a length of over 12 feet, of which half goes to the enormously elongated upper lobe of the tail, to the length and splashing activity of which the fish owes its names. The pectoral limb and the first dorsal fin are large; the snout is conical; the mouth and gill-apertures are moderately wide; the teeth are triangular and not serrated; the skin is bluish above, flesh-coloured below. The fox-shark follows

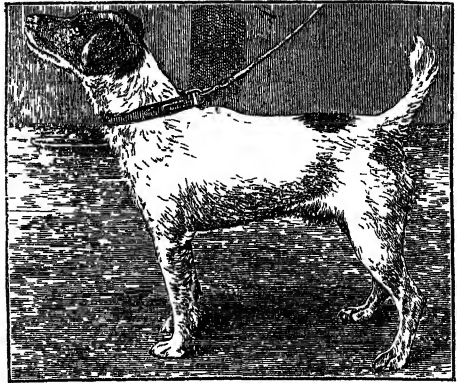

Fox-shark (*Alopias vulpes*).

shoals of herrings, pilchards, and the like, threshing the water with its tail as it swims round its victims, which it destroys in great numbers. In spite of its size it is not dangerous to man; and though some of the stories of its attacks on large whales are exaggerated, it has been seen to punish them severely. See SHARK.

Foxtail Grass (*Alopecurus*), a genus of Grasses, of which some species are much valued, particularly the Meadow Foxtail Grass (*A. pratensis*). This is one of the best meadow and pasture grasses of Britain, but does not arrive at full perfection till the third year after it is sown. It bears mowing well, and is reckoned a good grass for lawns. This, with Sweet Vernal Grass, is the earliest of British meadow grasses; it bears drought well, and thrives under trees. The Jointed Foxtail Grass (*A. geniculatus*), with an ascending culm bent at the joints, is very common in moist places, and cattle are fond of it, but it is a small grass. The Slender Foxtail Grass (*A. agrestis*) is an annual or biennial, of little value, although occasionally sown on very light sandy soils. See GRASSES, PASTURE.

Fox-terrier. The origin of the fox-terrier is somewhat obscure. From the earliest days of hunting a small dog has been used to follow the fox to its earth, but it is difficult to say when this dog became identical with the modern fox-terrier. The terriers which ran with hounds until the middle of the 19th century were of all colours and coats; their owners, acting on the adage 'handsome is as handsome does,' bred solely for work and not for appearances. The white terrier with hound marking being found most suitable, it was bred with care, and became a distinct breed. Some smooth fox-terriers were exhibited about the year 1865, and, speedily

catching the public taste because of their handy size and suitability to the house, soon became the most popular breed of the day. The wire-haired fox-terrier was not exhibited in public until

Fox-terrier.

the year 1872, the breed having a class set apart for it at Glasgow in that year. As the coat of this variety of the fox-terrier requires some attention, especially when kept for exhibition, it is not so common as the smooth section, though rapidly increasing in popularity. The chief points of the fox-terrier are: head, long, flat, rather narrow, but with powerful jaws and teeth; ears, small, V-shaped, and drooping forward; nose, black; eyes, small; back, short and strong; tail, generally cut short, set on high, carried gaily; fore-legs—an important point—must be straight, showing no ankle, good bone; hind-legs, rather straight, with long and powerful thighs; feet, round with arched toes; colour, white with black or tan markings—a point of little importance; weight, not more than 17 lb.; coat, in the smooth variety, short, hard, and dense; in the rough variety it should be half-an-inch long, but without any silkiness. The expression of the fox-terrier should be keen and hard, full of life and fire. Though the fox-terrier should not be quarrelsome, he should be ready to face anything in the way of his legitimate work. He is unequalled as a companion; and, as many fox-terriers have been kept for generations merely as companions, soft and degenerate specimens of the breed are common. But a genuine fox-terrier is of a bright and cheerful disposition, a splendid vermin-killer, fast enough to hunt, and small enough to enter an earth.

Foy. See FOWEY.

Foy, MAXIMILIEN SÉBASTIEN, French general, was born at Ham, 3d February 1775. During the early wars of the Revolutionary period he served as an artillery officer in Belgium, and on the Moselle and Rhine, till by 1800 he had risen to the rank of adjutant-general. In 1801 he commanded a brigade during the Italian campaign, and in 1805 a division of artillery in the Austrian campaign. Two years later Napoleon sent him to Turkey to assist Sultan Selim against the Russians and British, and his defence of the Dardanelles obliged Duckworth, the British admiral, to retire with loss. From 1808 to 1812 he commanded, as brigade-general, in Portugal and Spain, and was present at all the battles of the Pyrenees, being dangerously wounded at Othez in 1814. In 1815 he was again wounded at Waterloo, where he commanded a division under Ney. In 1819 he was elected deputy by the department of Aisne. In the chamber he was the constant advocate of constitutional liberty, and distinguished himself particularly by his eloquence in opposing

the war against Spain in 1823. Foy died at Paris, November 28, 1825. The *Histoire de la Guerre de la Péninsule* appeared in 1827, and in 1828 his *Discours*, with a biography by Tissot. See his *Vie militaire*, by Girod de l'Ain (1900).

Foyers, a stream of Inverness-shire, running 9 miles northward to the east side of Loch Ness, 10½ miles N.E. of Fort Augustus. During the last 1½ mile it makes a total descent of 400 feet, and forms two magnificent cascades, 40 and 165 feet high. The lower, called specially *The Fall of Foyers*, is one of the finest in Britain. In 1895-96 works were established for manufacturing, by electricity generated by the fall, aluminium out of bauxite brought from Ireland (see the article ALUMINIUM).

Foyle, LOUGH, an Atlantic inlet on the north coast of Ireland, between Londonderry and Donegal. It is 15 miles long, 1 mile wide at its entrance, and 10 miles broad along its south side; but part is dry at low-water, and its west side alone is navigable. Vessels of 600 tons ascend the lough, and, as far as Derry, the Foyle river, which, formed by the confluence of the Finn and the Mourne, has a north-north-easterly course of 72 miles.

Fra Angelico. See ANGELICO.

Fra Bartolommeo. See BARTOLOMMEO.

Fracastoro, GIROLAMO, an Italian physician and poet, famous for the universality of his learning, was born at Verona in 1483. At the age of nineteen he was appointed professor of Logic in the university of Padua. He afterwards practised successfully as a physician, and it was by his advice that the Council of Trent moved from Trent to Bologna to avoid the plague. Some years before his death, which occurred at Casti, near Verona, on 8th August 1553, Fracastoro abandoned medicine for letters, and became intimate with some of the leading scholars of the age. The chief of his numerous writings are: *Syphilidis, sive Morbi Gallici, Libri Tres* (1530; Lond. 1720); *De Vini Temperatura* (1534); *Homocentricorum sive de Stellis Liber* (1535); and *De Sympathia et Antipathia rerum* (1546). His collected works appeared at Venice in 1555, and his poetical works at Padua in 1728.

Fraction. In Arithmetic, when a unit of any kind is divided into any number of parts, each is termed a *fraction* of the whole unit—e.g. one foot (lineal measure) is divided into inches; one inch is thus a fraction of one foot. The usual notation employed to denote the value of a fractional quantity is to place under a horizontal line the number of equal parts into which the whole unit has been divided; above the line is placed the number of these parts actually contained by the fraction. The former number is known as the denominator, the latter as the numerator of the fraction. Thus, 7 inches is expressed as the fraction of one foot by $\frac{7}{12}$. Quantities expressed in this way are termed vulgar fractions; they are *proper* or *improper* according as the numerator is less or greater than the denominator; and when the numerator and denominator have no common factor the fraction is said to be in its lowest terms. When the denominator is 10, or a power of 10, the quantity is termed a Decimal Fraction (q.v.). In Algebra the term fraction, while including the sense of the arithmetical definition, is generally used to mean that any quantity affected by it is to be multiplied by the numerator and divided by the denominator. The addition, subtraction, multiplication, and division of fractions are performed according to rules which are practically the same both in arithmetic and algebra. Such rules will be found in any competent text-book on these subjects.

Continued Fractions.—Any expression of the form $a + \frac{1}{b + \frac{1}{c + \frac{1}{d + \&c.}}}$ is termed a *continued fraction*. This expression is usually for convenience abbreviated to $a + \frac{1}{b} + \frac{1}{c} + \frac{1}{d} + \&c.$ Such fractions may be terminating or non-terminating. A series of quantities which successively approach towards the actual value of such a quantity are termed *successive convergents* to the value of the fraction; they are alternately smaller and greater than its actual value. Such a series for the fraction above given is: $a, a + \frac{1}{b}, a + \frac{1}{b + \frac{1}{c}}, \&c.$

Vanishing Fractions.—When, by giving to one of the terms in a fractional algebraical expression a particular value, both the numerator and denominator become zero, the expression is said to be a *vanishing fraction*. Such is the case in the quantity $\frac{x^2 - 1}{x - 1}$, when $x = 1$; and in $\frac{x}{\sqrt{a + x} - \sqrt{a - x}}$, when $x = 0$. But in the first case, by dividing both numerator and denominator by $x - 1$, the true value of the expression is $x + 1$, which is equal to 2 when $x = 1$. In the second example, by multiplying above and below by the complementary surd—viz. $\sqrt{a + x} + \sqrt{a - x}$, the fraction becomes equal to \sqrt{a} , when $x = 0$. Such methods for finding the true value of vanishing fractions are all more or less tentative. For a general process by which their value may be found, reference may be made to Williamson's *Differential Calculus*, chap. iv. See also article CALCULUS.

Fractures, in Surgery, are classified in several different ways. As regards the fractured bone itself, it may be merely broken across, either transversely or obliquely, the commonest injury; or broken into several pieces (*comminuted fracture*); or only cracked (*fissured fracture*, the most usual fracture of the skull); or partly broken, partly bent (*greenstick fracture*, occurring in the bones of the limbs in children); or one part of the bone may be forcibly driven into the other (*impacted fracture*). But the most important classification of fractures is concerned with their relation to the surrounding parts. In a *simple fracture* there is no wound of the skin communicating with the fracture; in a *compound fracture* there is such a wound; in a *complicated fracture* there is some other injury (e.g. a flesh-wound not communicating with the fracture, a dislocation, a rupture of a large blood-vessel). The distinction between simple and compound fractures is of special importance, as the latter are very much more serious than the former, chiefly on account of the risk of pyæmia or septicæmia, and their repair much more tedious; though the dangers attending them have much diminished since the introduction of the antiseptic method. See ANTISEPTIC SURGERY.

Fractures are most common in the long bones of the limbs, particularly the collar-bone, the radius just above the wrist, the thigh-bone, and the fibula. They are rather less frequent in children than in adults, and much less in women than in men.

Causes of Fractures.—The *predisposing* causes which render bones specially liable to fracture may be local—e.g. necrosis or tumour affecting a single bone, or general—e.g. locomotor ataxia and some other nerve diseases, the diseases called mollities and fragilitas ossium, and old age, all which render the bones generally less able to bear a strain. The

immediate cause may be either *external violence* or *muscular action*. The external violence producing a fracture may be either *direct* or *indirect*. In direct fractures the bone yields at the point where the force is applied, and there is always more or less bruising of the adjacent soft parts by the body which causes the fracture—e.g. when a limb is broken by a heavy wheel passing over it, or a stone falling upon it. In indirect fractures the bone gives way at some point between two opposing forces, and the adjacent tissues are not injured except by the broken ends of the bone—e.g. when a person falls upon his hand, and the radius or humerus gives way. The worst fractures are thus in general those produced by direct violence. Muscular action not infrequently leads to the fracture of bones into which powerful muscles are inserted, particularly the knee-cap, by simply tearing them asunder. The subject of the injury may then fall, and attribute the accident to the fall, whereas the reverse is the case. This form of accident may happen, for example, in an old person who breaks the neck of the femur by a sudden twist, and then falling down, does himself some further injury, such as impaction of the fracture, in the fall.

Symptoms of Fracture.—Fracture of a limb is attended by pain, swelling, and loss of power; but these do not suffice to distinguish it from other forms of injury. Deformity other than swelling (shortening, angling, or unnatural rotation of the injured limb), abnormal mobility at the seat of injury, and a rough grating sound and feeling (called *crepitus*) when the limb is so moved as to rub the broken surfaces together are the most satisfactory evidences of fracture. The patient, moreover, may have observed the sound of the break when the bone gave way. But in a case where fracture is suspected X-ray examination now affords an indispensable method of examination, which often reveals small fractures not otherwise discoverable. X-ray examination also gives valuable information as to the position in which the fragments lie.

Repair of a Broken Bone.—The immediate result of a fracture is considerable extravasation of blood into the tissues around it, from the blood-vessels torn across by the injury. It is not quite certain whether some of this blood takes part in the healing process; most of it at all events is simply absorbed. But during the days following the fracture inflammatory lymph, together with new formative tissue cells (here called *callus*), is thrown out between and around the broken ends of the bone. Slow organisation of the callus, with formation of fibrous tissue and blood-vessels, takes place, lime salts are deposited, and in from three to eight weeks it is usually converted into bone, firmly cementing the fragments together. In man, when the fracture is set in good position, there is generally little more lymph effused than suffices to restore the natural outline of the bone; but in animals the break is generally ensheathed in a large mass of it, called *provisional callus*, which steadies the bone till the *permanent callus* between the ends of the bones has become ossified; then the provisional callus, being no longer necessary, is absorbed.

Treatment of Fracture.—When a fracture has taken place it is important that there should be as little disturbance as possible of the injured part till it is to be finally adjusted by the surgeon. Many simple fractures, especially of the lower limb, are made compound by ignorance or carelessness on the part of the injured person or of officious onlookers. The injury should therefore be attended to first on the spot where it has been received; the limb should be fixed by handkerchiefs or strips of cloth to anything at hand firm enough to keep it tem-

porarily steady (a walking-stick, rifle, broom-handle, &c.), or, in the case of the lower limb, to the other leg. When this has been done the patient may more safely be removed to the place where he is to remain during treatment.

The object of the surgeon in *setting* a fractured limb is to place the fragments as nearly as possible in their natural relation, and to retain them firmly in this position during healing. The first object is attained by pulling on the limb (*extension*) so that the displacement is corrected, and the limb is left in a comfortable position. Retention in this position is effected by applying some form of *splint* or external rigid apparatus to the limb, differing in material, shape, and method of application according to the seat of the fracture. Splints are usually made of wood, polyplastic felt, or metal, and fixed on by straps or bandages; but in some simple fractures, especially of the lower limb, a bandage is used impregnated with some material, like plaster of Paris or silicate of soda (water-glass), which hardens on drying and forms a case for the limb; in this way confinement to bed may be much shortened. It is necessary in some cases to continue the extension, and this may be effected by attaching weights, which act over a pulley, upon strips of plaster fixed to the broken limb.

Treatment of fractures may lead to an unsatisfactory result in either of two contrary ways: when the vitality is low, or the treatment has not secured perfect rest of the broken bone, it may become united merely by fibrous tissue instead of bone, leaving a flail-like useless limb (*ununited fracture*, or false joint); or, when rest has been too long and continuous, the healing process may not merely reunite the bone, but fix the surrounding tendons and ligaments by fibrous adhesions, leaving more or less obstinate stiffness of the neighbouring joints. The former is in general more apt to occur in the shafts of the long bones, the latter close to their ends, and the treatment must be modified accordingly.

Fractures of the bones of the head and trunk are dangerous more on account of the risk of laceration of the important organs enclosed by them than because of the injury to the bones themselves; and in general any attempt to 'set' such fractures is apt to do more harm than good. Means must simply be taken to keep them as much at rest as possible.

Fra Diavolo, properly MICHELE PEZZA, a celebrated Italian brigand and renegade monk, born at Itri, in the Terra di Lavoro, in 1760. Of plebeian origin, he at first followed the trade of stocking-weaver, then entered the Neapolitan army, and subsequently the service of the pope; finally he abandoned military life and became a monk, but, being expelled for misconduct, withdrew to the mountains of Calabria, where he headed a band of desperadoes, whose strongholds lay chiefly along the frontier of the Terra di Lavoro. Pillage, bloodshed, and atrocious cruelties signalised his career. For years he evaded the pursuit of justice by retiring to his haunts amidst mountains and forests, and skilfully defeating, with much inferior numbers, all the armed forces despatched against him. He became at length known among the peasantry of the neighbourhood as Fra Diavolo. On the advance of the French into the Neapolitan states, along with his band he warmly espoused the royal cause, and in return they were not only pardoned and reinstated in civil rights, but promoted to the grade of officers in the royal army, Fra Diavolo himself becoming colonel. In 1806 he attempted to excite Calabria against the French, but was taken prisoner at San Severino, and was executed at Naples on the 12th November. The opera of Auber has nothing in common with Fra Diavolo but the name.

Fraga, a town of Spain, on the Cinca, 63 miles ESE. of Saragossa, the centre of a district famous for a variety of small green figs, which are dried before being consumed. Here, in 1134, the Moors defeated Alfonso I. of Aragon. Pop. 8000.

Fragaria. See STRAWBERRY.

Fragonard, JEAN HONORÉ, painter, was born at Grasse in 1732. He studied under Chardin and Boucher; and, entering the academy schools, gained the 'prix de Rome' in 1752. In Italy—which, later, he revisited—he was influenced mainly by the works of Tiepolo, the last of the great Venetians; and he executed many illustrations for Saint-Non's *Voyage de Naples et de Sicile*. Returning to France, he in 1765 received 2400 francs from Louis XV. for his 'Callimaché,' commissioned for reproduction in Gobelins tapestry; then he ceased to be academic, and began to be personal, to follow his true bent—helped to be most himself by the art of Venice and by the art of Rubens. He painted, with a loose touch and luscious colouring, *genre* pictures of contemporary life, or of scenes which, however titiled, drew their inspiration from present actuality, from humanity seen and observed by the painter himself. To these his ardent and sensuous southern temperament gave both force and charm. He is also known by his landscapes. He is well represented in the Louvre, most typically in its La Caze collection by such works as 'Bacchante Endormie' and 'La Chemise Enlevée.' He died in Paris, 22d August 1806.

Framboesia. See YAWS.

Frame, in Gardening, a term usually applied to movable structures used for the cultivation or the sheltering of plants. The most common form is that of the ordinary hotbed frame, which is a rectangular box of any convenient dimensions covered with glazed sashes; but they are made in many forms, according to fancy and the purpose for which they are particularly required.

Framingham, a town of Massachusetts, on the Sudbury River, 24 miles W. by S. of Boston by rail. It includes Saxonville and South Framingham, with manufactures of rubber and stiaw goods. Pop. 17,000.

Framlingham ('strangers' town'), a market-town of East Suffolk, 14 miles NNE. of Ipswich. It consists of a spacious market-place, with a few streets branching off irregularly. The fine flint-work church, restored in 1888-89, has a tower 90 feet high, and contains several noble altartombs of the Howards (the third Duke of Norfolk, the poet Earl of Surrey, &c.). Separated by the Mere from the red-brick Albert middle-class college (1864) rises the great Edwardian castle, reduced in 1650 to a mere shell, but retaining its thirteen square towers. The stronghold successively of Bigods, Mowbrays, and Howards, it was Queen Mary's refuge after Edward VI.'s death. Pop. 2000. See Hawes's *History of Framlingham* (1798).

Franc, a French silver coin which forms the unit of the French monetary system. Introduced into France 6th May 1799, it was extended to the other countries comprised in the Latin union—viz. Belgium, Italy, and Switzerland—by the convention of 1865, and has since then been adopted by Rumania (1868), Spain (1871), Serbia (1874), Bulgaria (1880), and Greece (1882). In Belgium and Switzerland it is known as the franc; in Italy, *lira*; in Greece, *drachma*; in Rumania, *lei*; in Serbia, *dinar*; in Spain, *peseta*; in Bulgaria, *levu*. The franc is coined of silver, $\frac{835}{1000}$ fine, and weighs five grammes, its value at par being about 93d. English money, or 19 cents of United States. One pound sterling = 25.2 francs. The franc is divided into 100 centimes, but the old division into 20 sous,

valued at 5 centimes each, is still made use of in common life. There are in France silver coins of $\frac{1}{2}$, 1, 2, and 5 francs; and gold pieces of 5, 10, 20, 50, and 100 francs. See DECIMAL SYSTEM.

Francatelli, CHARLES ELMÉ (1805-76), born in London of Italian family, was a famous London chef and writer on cookery.

Francavilla, in the Italian province of Lecce, 22 miles WSW. of Brindisi, has a pop. of 20,000.

France occupies a commanding position between the Atlantic and the Mediterranean. The civilisation developed on the coasts of the Mediterranean eventually found an easy passage towards the Atlantic and the North Sea by the broad valley of the Rhone and Saône, which communicates with the drainage areas of the Seine, the Loire, and the Garonne. The territory now occupied by France thus became the ground upon which Roman civilisation met and melted with the civilisation of the Celts and Teutons; and it gave birth to a race which assimilated a variety of ethnographical elements—Gaulish, Italian, Spanish, German, and Flemish—and developed into a powerful nationality, the French.

In its present limits, augmented in 1919 by the reacquisition of Alsace and Lorraine (5390 sq. m., 1,874,000 inhabitants), France covers just under 213,000 sq. m.—one-eighteenth part of Europe—and had in 1921 a population of 39,209,766, including Alsace-Lorraine. It is bounded on the N. by the English Channel and the Strait of Dover, which separate it from England; on the NE. by Belgium and the grand-duchy of Luxemburg; on the E. by Germany, Switzerland, and Italy; on the S. by Monaco, the Mediterranean Sea, Andorra, and Spain, from which it is separated by the Pyrenees; and on the W. by the Atlantic Ocean. Its utmost extremities are comprised between 51° 5' and 42° 20' N. lat., and the longitudes of 5° 9' W. and 8° 14' E. In shape it is a compact hexagonal mass, symmetrically distributed on both sides of the meridian of Paris, its greatest dimensions being 606 miles from N. to S., 583 miles from W. to E., and 675 miles from NW. to SE.

The areas of the different administrative subdivisions of France, and their populations, as well as the former divisions into provinces, are given in the table on the next page.

Coasts, Seaports, and Islands.—The coasts of France possess great advantages for maritime intercourse with the world. The eastern part of the Mediterranean coast, owing to its crescent-shaped indentations, has several excellent harbours which combine the advantage of being situated at, or close by, the terminus of the great commercial route connecting north-west Europe with the Mediterranean (Golfe de St Tropez, Hyères roads, Toulon, Marseilles); on the other hand, the western portion of the same coast, which describes a broad curve in the Gulf of the Lion, is flat and difficult of access, as are also the shores of the Bay of Biscay in the Atlantic. The deep estuary of the Garonne has a good port in Bordeaux; for Nantes, at the head of the estuary of the Loire, owing to the shallowness of its entrance, a deeper port has been found in St Nazaire; whilst the port of La Palisse, three miles west of La Rochelle, is steadily rising in importance. Farther north the rocky coasts of Brittany are indented with numerous narrow gulfs, and dotted with small islands; and Brest, situated on one of the gulfs, is among the best ports in Europe. On the northern coast, facing towards England, France has but few natural harbours. Cherbourg, at the extremity of the Cotentin peninsula, has been made a naval port at a heavy outlay. Le Havre, at the mouth of the Seine, also is an artificial port, whose maritime intercourse with distant lands

and England is very extensive—as is that of Rouen (up the Seine) and the Channel ports, Dieppe, Boulogne, Calais, and Dunkirk.

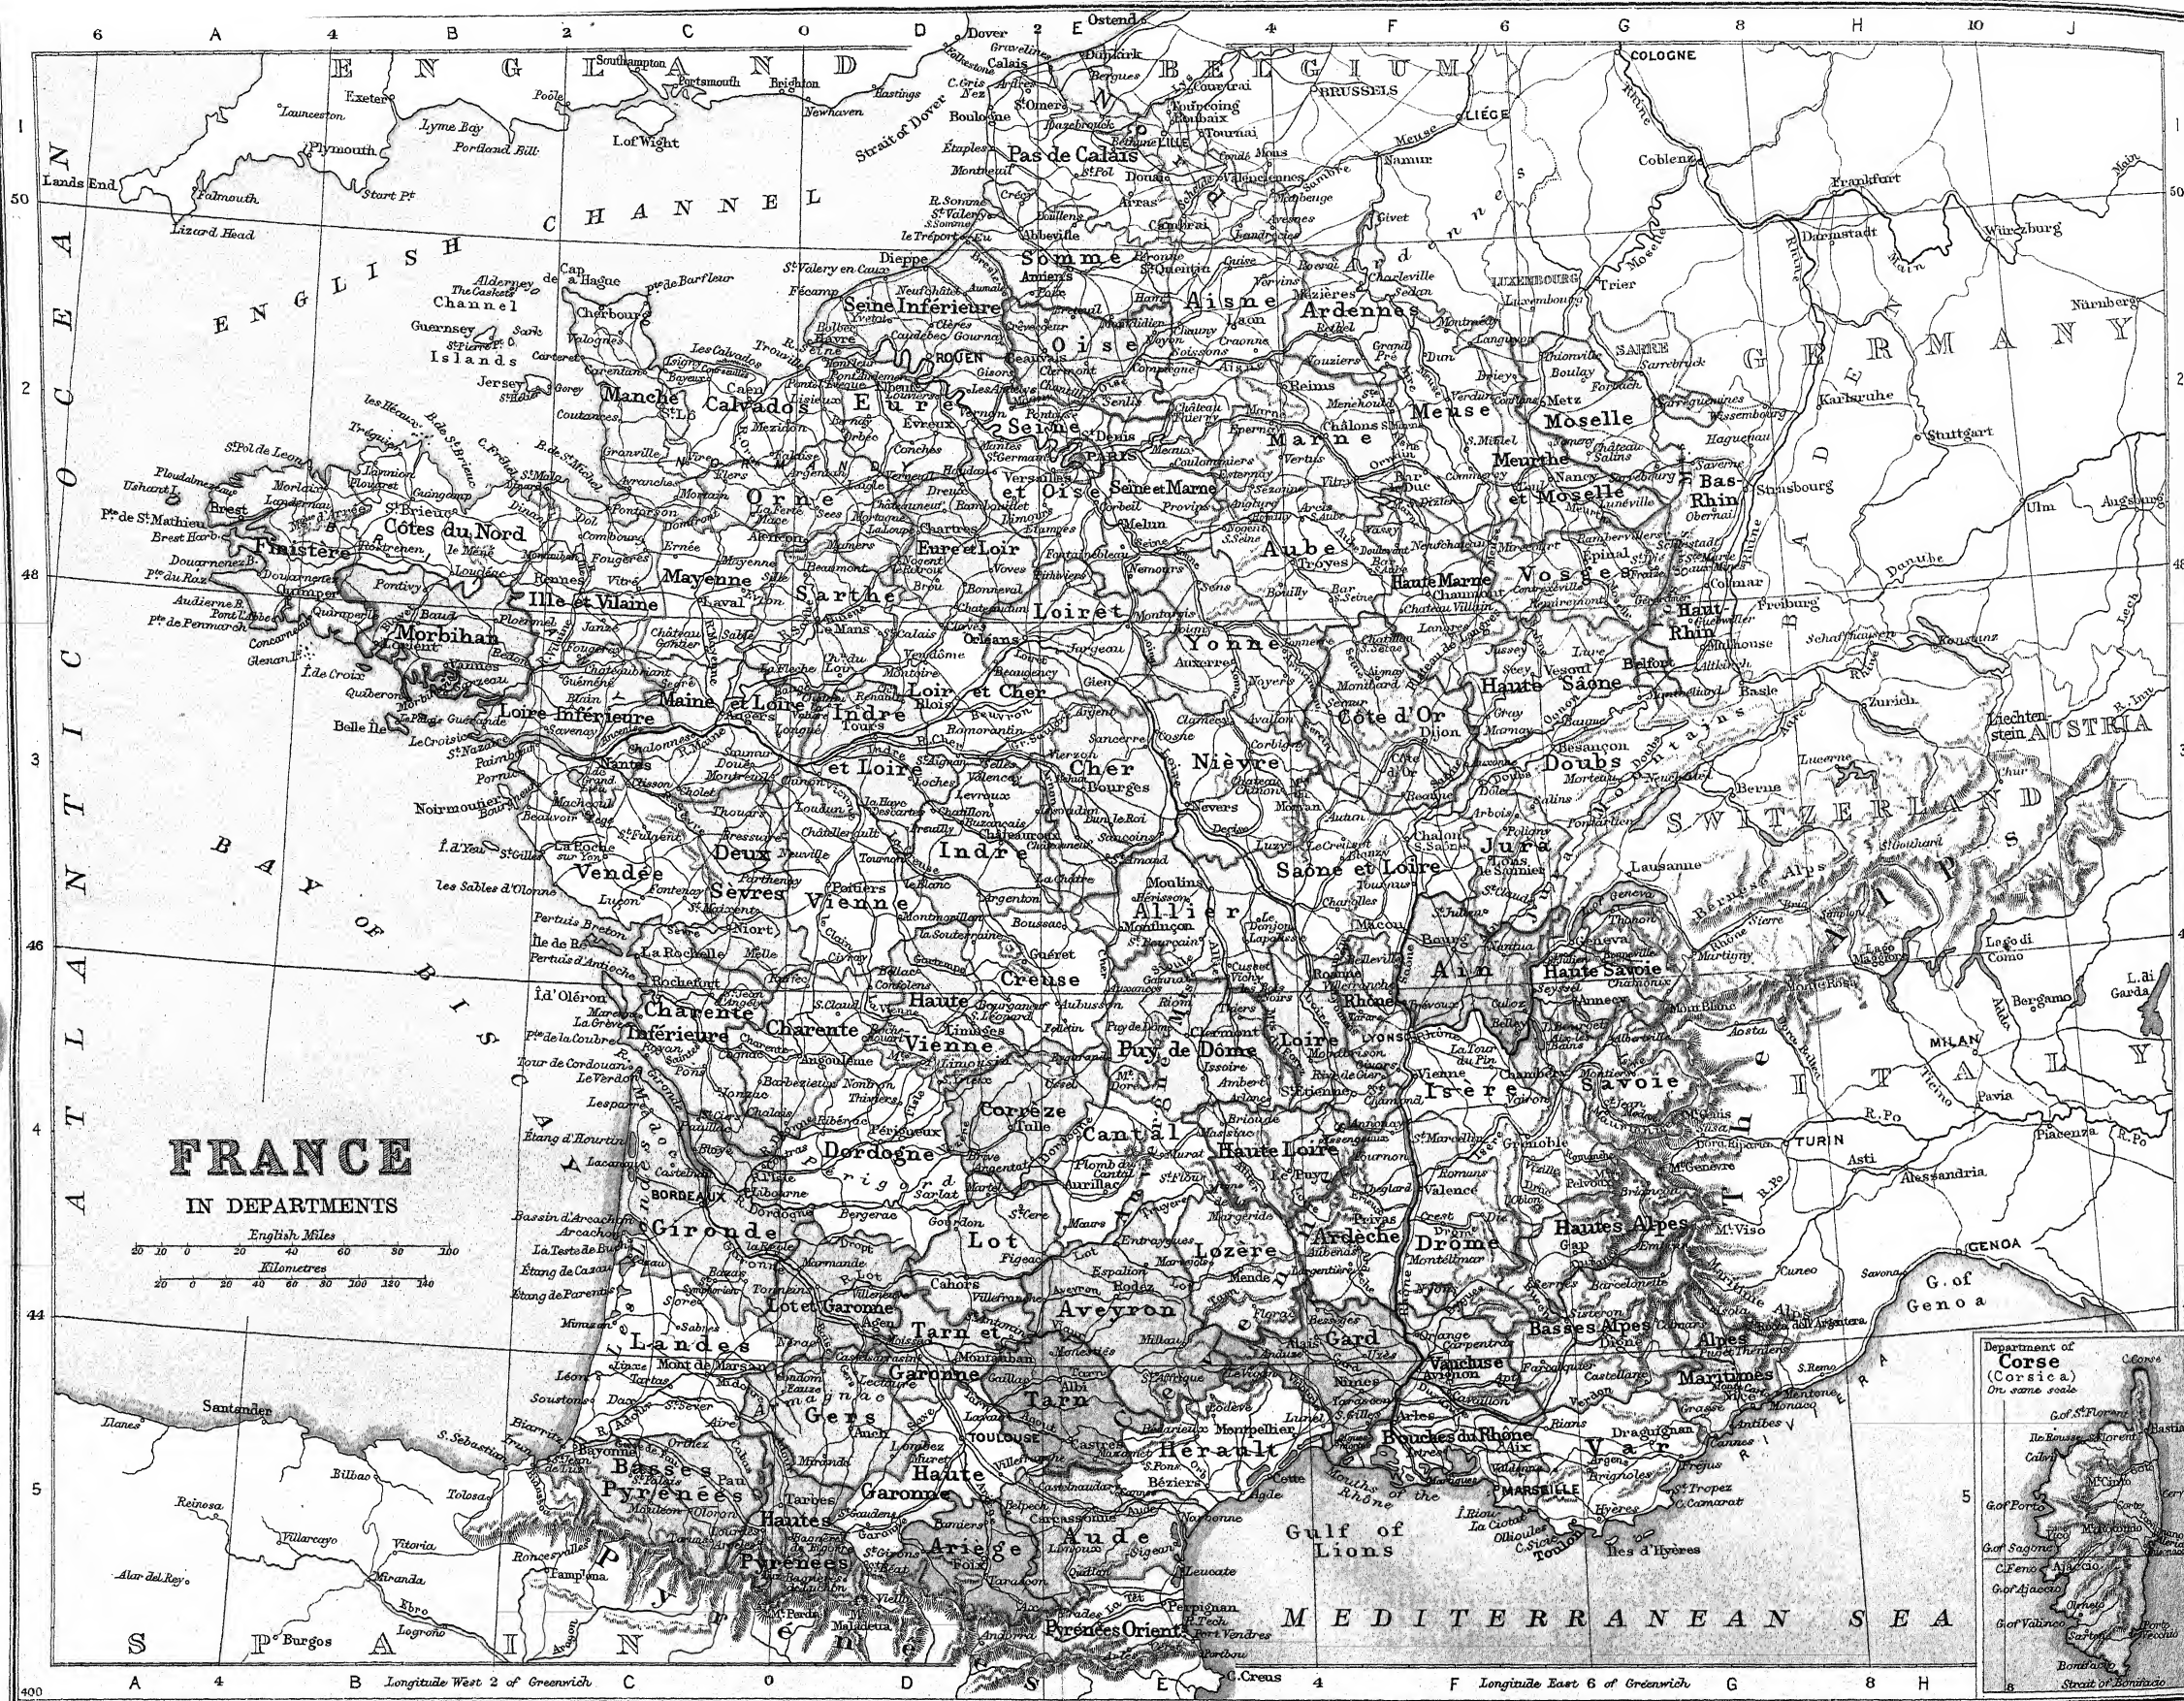

Except Corsica, which geographically belongs rather to Italy, France has no islands of consequence, the Channel Islands being British.

Colonies—The overseas possessions of France in extent and importance are surpassed only by those of the British Empire. Canada and India were lost to France in 1759-63; Napoleon sold Louisiana to the United States of America, and his downfall in 1814 deprived his country of all but a few small islands and settlements abroad. By 1914, however, a vast new colonial empire had been built up, including North-west Africa almost *en bloc*, Madagascar, and Indo-China. Algeria, where there is most scope for European immigration, is in certain respects treated as part of France; Tunis and Morocco are protectorates; Syria, Cameroon, and Togo are territories mandated by the League of Nations; the New Hebrides (not included below) are under joint Franco-British administration.

GRAND TOTAL		4,612,000	61,865,000

Geographical Description.—France is mountainous only in its south-eastern half—south of a line from Biarritz to Metz. The Pyrenees form its southern border; the Alps and the Jura in the east separate it from Italy and Switzerland; farther north the Vosges run between Alsace and Lorraine. The Cévennes, west of the deep Rhone Valley, and (in the heart of France) the mountains of Auvergne

mark the culminating points of a great central plateau. The climate of France, its vegetation, the distribution of its population, and its very history have been determined by these leading features of its orography.

The Plateau.—The extensive mass of elevated plains which rises between the lowlands of the Mediterranean coast and those sloping towards the Atlantic reaches a height of from 3000 to 4000 feet in its higher central parts only; several chains, partly of volcanic origin, piled over its surface, attain from 5000 to 6000 feet; while the river-valleys are dug so deeply into the plateau that it often assumes a hilly aspect. The whole slopes gently towards the north-west, gradually melting into the lowlands of the Garonne, the Loire, and the Seine, which would be submerged almost entirely if the level of the ocean rose 1000, or even 600 feet. In the latter case the Atlantic coast-line would run from the western Pyrenees towards the Ardennes, with detached islands to represent the highlands of Brittany and Normandy, and to the south of these two broad and deep gulfs, corresponding to what are now the upper drainage areas of the Garonne and the Loire; while the Mediterranean Sea would send into the mainland a long and wide gulf up the valley of the Rhone, with a narrow elongated lake penetrating farther north, and corresponding to what is now the valley of the Saône.

It is easy to grasp at once how such a configuration facilitated the intercourse between the Mediterranean Sea and the Atlantic Ocean. The shores of the Gulf of the Lion, which at an early period of history were dotted with Greek and Roman cities, are separated from the Garonne by only a low watershed, the *Seuil-de-Naurouse* (636 feet above the sea), which allows easy communication with the Bay of Biscay. Farther north the depression of the Saône, which is a natural continuation of the valley of the Rhone, is connected with the Loire by a valley of so gentle a gradient that it has been utilised for a canal (the *Canal du Centre*), the highest part of the watershed being but 1000 feet above the sea; and, finally, the same depression of the Saône freely communicates across the lower parts of the plateau with the tributaries of the Seine. The civilisation which developed on the littoral of the Mediterranean thus found three natural passages leading to the Atlantic Ocean and the coasts of the North Sea, without having to contend with any of the natural obstacles opposed elsewhere by the Alps.

While sloping gently towards the north-west, the plateau has a short steep slope towards the valley of the Rhone and the Mediterranean coast, and the southern part of that slope is fringed by the Cévennes Mountains, which raise their granitic and crystalline summits to more than 5000 feet above the sea (chief summit, *Mont Lozère*, 5584 feet). This lofty chain separates two entirely different worlds—the fertile, sunny, and warm plains of the Lower Rhone and Languedoc from the plains of the Rouergue, dreary, cold, and 3000 feet high, upon which chiefly rye is grown, and flocks of sheep find rich grazing-grounds. Farther north the mountains on the edge of the plateau become much lower. The *Monts du Vivarais* reach their greatest height in *Mont Mézenc* (5754 feet), while the *Monts du Beaujolais* and *du Charolais* as a rule do not exceed 3300 feet. The sunny slopes of the *Monts du Beaujolais*, turned towards the Saône, are covered with rich vineyards; while the plateau to the west of them is dotted with ironworks, coal-mines, and manufacturing cities. Still farther north the plateau, which is separated by only the narrow valleys of the Saône and the Doubs from the hills of the Jura, is fringed by the low dome-shaped hills of the *Côte-d'Or* (2000 feet),

which connect it with the Vosges. The upper tributaries of the Seine have their source in the same wet district as those of the Saône, and both rivers are connected by the Burgundy Canal. Finally, the Vosges, although making a steep descent to the valley of the Rhine, rise but gently over the plateau, their highest points being less than 5000 feet above the sea (*Ballon de Soultz*, 4672 feet). Thick forests still clothe the slopes of the Vosges (and their continuation, the *Hart*), which are covered with morainic deposits of the glacial period, and their numberless streams are dotted with sawmills and factories.

The plateau reaches its greatest height of from 3300 to 4000 feet in central France—in the *Massif Central of Auvergne*, which covers fully one-seventh of France's total area, and is a region of granites, gneisses, and crystalline slates fringed by Jurassic deposits, and dotted on its surface with extinct volcanic cones surrounded by wide sheets of lava. The *Massif du Cantal*, connected by the *Margeride* chain with the Cévennes, rises nearly 2000 feet above the level of the plateau, reaching 6093 feet above the sea in its highest volcanic cone, the *Plomb du Cantal*. The *Monts Dore*, 40 miles north, have the same character; their chief summit, the *Puy-de-Sancy* (6188 feet), surrounded by several lower volcanic cones, being the highest mountain of central France. Finally, the *Monts Dôme*, a few miles farther north, consist of some fifty volcanic cones, the highest of which is *Puy-de-Dôme* (4806 feet). The *Limousin* and the *Marche*, to the west of the above, are granitic plateaus hardly reaching 3300 feet above the sea; while the *Causses* of the *Rouergue*, in the south, are built up of Jurassic limestones deeply cut into by rivers which flow in beautiful cañons; towards the north-east the *Massif Central* is continued by the *Morvan*, and, farther north-east, by the much lower plateaus of western Lorraine and *Champagne Pouilleuse*, which slope with a very easy gradient towards the plains watered by the Seine. As to the Ardennes (between the *Meuse* and the *Moselle*), which have played so important a part in military history as a bulwark against foreign invasions, they are a plateau from 1600 to 2400 feet high, still covered with wide forests, and intersected by marshy depressions, ravines, and fertile valleys. The heights of the *Massif Central*, suffering as they do from a protracted winter, have but a poor, rapidly-diminishing population. The forests which once covered them have mostly been destroyed, save in the picturesque *Margeride* chain, and only flocks of sheep graze on their meagre pasture-grounds. The *Causses* receive rain in abundance, but are exceedingly dry—the water rapidly disappearing in the numberless crevices of the soil. The inhabitants are thus compelled to gather rain-water in cisterns for themselves and their cattle. A few acres, cultivated here and there, bear poor crops of barley, oats, and potatoes; but hundreds of thousands of sheep are kept for the special purpose of making cheese. As a rule the plateau is thinly peopled, save in the mining and industrial regions. Farther north-east, where it is much lower, and where the broad valleys between the wooded hills have a more fertile soil, a denser population gathers in the villages and the towns, and finds the means of existence in agriculture combined with a variety of small industries.

The Jura.—A narrow passage near *Belfort* (la *Trouée de Belfort*), utilised by both the canal which connects the Saône with the Rhine and the railway which leads from Paris to Switzerland, separates the Vosges from the limestone plateaus of the *Jura* (*Crêt de la Neige*, 5553 feet). The depressions and high valleys between the forest-clad hills shelter a large and laborious population, which

is supported by a combination of agriculture and cattle-breeding with a variety of petty trades.

The Alps.—Since the annexation of Savoy in 1860 the Alps of Savoy, as well as a portion of the main chain, including the northern slopes of the chain of Mont Blanc (15,780 feet), belong to France. The pass of Little St Bernard (7190) separates the latter from the Graian Alps, which have the two passes of Mont Cenis (6883) and Mont Genève (6802) leading from France to Italy, and are continued to the south-west by the Oisans group, where immense glaciers rivaling those of Switzerland gather around Mont Pelvoux (13,462). The valley of the Durance separates the Graian Alps from another short parallel chain of the Cottian Alps (Monte Viso, 12,608), while the still lower Maritime Alps descend in terraces to the Mediterranean coast. The cold and snowy slopes of the Alps are but thinly peopled, especially in the dry limestone spurs of the Graian and Cottian Alps. A number of agricultural villages, however, thrive in the lower spurs of the Savoy Alps, and the city of Grenoble is an industrial centre of importance; while Chamouni at the foot of Mont Blanc is one of the chief centres for tourists.

The Pyrenees.—This wild complex of lofty chains extends for a length of 260 miles between the Atlantic Ocean and the Mediterranean Sea. In the east it is built up of three parallel chains running in a north-eastern direction: the Monts Albères, the Sierra del Cadi, which enters France from Spain and has on French territory the lofty peak Mont Canigou (9137 feet), and the chain of south-east Andorra, continued in France by the peak Puy-de-Carlitte (9583). Farther west the Pyrenees proper consist of parallel chains of wildest aspect, running west-north-west and disposed in *echelons*. Here we find the highest peaks: Néthou (11,168) in the Maladetta chain, Posets and Mont Peidu (11,000) are in Spain, but Vignemale (10,820) on the frontier is French, with other giants of over 10,000 feet. Wide *cirques*, which formerly were filled with *névés* and gave origin to vast glaciers, and arid mountains intersected by narrow and dark valleys are characteristic of that part of the Pyrenees; but the Pyrenean glaciers of our own time are much inferior to those of the Alps, and none descends lower than 7260 feet. The Pass of Ronçevaux (Roncesvalles, 40 miles from the Atlantic coast), which has been the route of so many migrations, separates the Pyrenees proper from a series of much lower spurs of the Spanish coast-ridges, which, like the Mediterranean coast-ridges, also have a north-eastern direction. The passes across the Pyrenees proper are very few, very high, and difficult. The Pass of Ronçevaux in the west and in the east those of La Perche and (16 miles only from the Mediterranean) Perthus lead through longitudinal valleys of the chains running north-east which enclose the Pyrenees at both ends. Of the passes through the Pyrenees proper none is lower than 5400 feet. The railways connecting France with Spain have consequently been compelled to follow the very coasts of the Atlantic Ocean and the Mediterranean, but the Central Pyrenees are to be pierced and crossed by lines up the Ariège, Salat, and Aspe valleys. A plateau, from 1600 to 2000 feet high (Lannemezan), spreads out at the northern foot of the Pyrenees. Owing to its limestone soil it is exceedingly dry, and its grazing-lands have had to be irrigated with water derived from the Neste River.

Plains and Rivers.—The whole of north-western France, with the exception of a few hilly tracts in La Vendée, Brittany, and Normandy, is occupied by wide plains which constitute the real wealth of her territory. Taking them in order from the south-west, we have first the Landes—a wide

triangular space between the Bay of Biscay, the Adour, and the Loire, covered with Pliocene sands, which would be an immense marshy fever-den, bordered by shifting sands on the sea-coast, if it were not intersected by canals, and the sands were not fixed by plantations of trees. The thick growths of bushes which cover the plain are utilised as grazing-grounds for flocks of sheep, the shepherds formerly being compelled to mount upon stilts when watching their flocks. Some of the ponds—formerly bays, now separated by sand-dunes from the ocean—are valuable fishing-grounds. The Adour (187 miles long), which fringes the Landes and receives a number of tributaries (*gaves*) from the chalky plateau of Lannemezan, has but few important cities on its course—Bayonne being the chief of them. The Garonne (346 miles), which rises in Spain, and receives the Tarn and the Aveyron from the very depths of the Massif Central, is a most important channel for navigation. But the torrential rains which pour over its drainage area of 22,080 sq. m. do not always find an easy outlet in its channel, and floods are not unfrequent. The Dordogne (305 miles), which rises in the Mont Dore, has most of its course dug into the plateau. Beautiful vineyards cover the slopes of its valley, while lower down the raising of iron ore and the quarrying of grinding-stones, as also the industry of truffle-hunting in Périgord, become a source of prosperity; the old city of Périgueux is an important centre of manufactures. The Dordogne and the Garonne join to form the Gironde, which is a true marine estuary, with the left bank bordered by the low hills of Médoc, covered with vineyards yielding every year vast quantities of the finest red Bordeaux wines. The great port of Bordeaux, on the Garonne, is some 15 miles above the head of the estuary of the Gironde.

The monotony of the rich plains between the Gironde and the Loire, which include the old province of Poitou, is broken by the dreary hills of the Gâtine, a link between the chains of Margeride and Limousin and the hilly tracts of Brittany. The southern parts of the plains on the right bank of the Gironde—the Saintonge (watered by the Charente)—are among the richest districts of France. Farther north the Bocage closely reminds one of England by its meadows enclosed within rows of trees, while Le Marais, on the coasts of the Gulf of Poitou, which has the two islands of Ré and Oléron protecting the entrance to Rochefort, resembles the *polders* of the Netherlands.

Next we have the immense plains watered by the Loire, which becomes a great river after receiving the Allier, and has a drainage area covering more than one-fifth of the entire area of France (46,750 sq. m.), and a total length of 670 miles. This longest river of France rises on the plateau not far to the west of the middle of the Rhone's lower course, and describes a wide curve towards the north, approaching within 70 miles of Paris at the head of the bend at Orleans. It enters the Atlantic Ocean by a wide estuary, pouring out of its broad channel into the sea a vast or meagre volume of water in time of flood or drought. The regions along its middle course are the real heart of France. As it issues from the valleys of the plateau it waters the Sologne, formerly the chief rye-producing region; the Berry, to the south of the Sologne, a chalky plain from 350 to 700 feet high, interspersed with numerous ponds and with rich pasture-grounds; and Beauce, situated between Paris, Orleans, and Tours, quite flat and covered with cornfields and meadows. The Gâtinais, to the east of Beauce, spreads between the two great forests of middle France—the Forêt d'Orléans (which covers 84,600 acres) and the Forêt de Fontainebleau (41,700). Farther down

its course the Loire enters the lowlands of Touraine and Anjou, which are literally covered with corn-fields, gardens, and vineyards, while the cities of Tours, Saumur, and Angers are centres of manufacturing industry. The beautiful meadows, corn-fields, and gardens continue as far as Nantes, where the Loire enters its estuary. With the deepening of the river channel Nantes is regaining its maritime importance, vying with its *avant-port*, St Nazaire, and is, too, a busy manufacturing town.

The peninsula of Brittany is formed by two ridges of granitic hills, from 1000 to 1200 feet high, separated by a region of crystalline slates. Its scenery and moist climate, as well as those of the Cotentin peninsula, again remind one of England, with the meadows and fields fringed by trees, and the ivy-covered houses. Cattle-breeding on a large scale, poultry-farming, fruit-gardening, agriculture, and fishing are the chief riches of Brittany, as of Normandy, a land famed for its cider. The plateaus of Normandy and Maine, which rise from 1000 to 1300 feet above the surrounding plains, are covered with meadows, corn-fields, and forests. The Seine separates them from the Cretaceous chalky plains of the Caux, which raise their cliffs over the Channel, and are deeply cleft by fertile valleys.

The Seine (485 miles), which rises in the hills of Morvan, and drains with its tributaries (chiefly on the right bank) an area of 30,030 sq. m., certainly is behind the Loire in length, volume, and size of drainage basin, but is far superior for navigation purposes. The wide Tertiary basin which it and its tributaries water has from remote antiquity been the dominant portion of historical France. Numerous large cities, like Auxerre, Sens, Troyes, Châlons, Reims, Laon, Rouen, which all took such an important part in the making up of France—and especially Paris, which acquired its importance owing to its most advantageous position at the intersection of all the chief routes crossing France—are situated either on the Seine, or on its right-bank tributaries which water the fertile plains of Champagne. Le Havre is the great port at the mouth of the river.

Artois and French Flanders are low tracts of land to some extent conquered from the sea. Their flourishing agriculture, vast coal-fields, and the great industry of their chief cities (Amiens, Lille, Roubaix) suffered sadly in the European War.

At the other extremity of the republic the lowlands of the south occupy the sea-coast and the broad valley of the Rhone, along which they extend between the Alps and the plateau, as far north as Lyons, to be continued farther north by the valley of the Saône.

The Rhone (507 miles) has its source in the glaciers of the St Gothard group, and of its 38,180 sq. m. drainage area—densely inhabited around Lyons—nearly one-tenth belongs to Switzerland. Below the Lake of Geneva its course is still in the mountains, and it is not far from its junction with the Saône at Lyons that it enters the plain of Dauphiné, dotted with numerous industrial cities. At Lyons the Rhone at once changes its westerly course, to flow rapidly due south in a rich valley, the slopes of which are covered with vineyards. Below Avignon the valley suddenly assumes a decidedly southern character, not unlike the driest parts of Sicily and Greece. The Isère, which rises in the Graian Alps, the Durance, which flows from the Cottian Alps, and a number of smaller streams rushing from the Cévennes join the Rhone, which bifurcates at Arles, leaving the marshy delta of the Camargue between its two main branches, and the gravelly plain of the Crau to the left. The tides being insignificant, the mouth of the Rhone is rapidly obstructed by mud

and sand. A canal permits ships to enter the river at Port St Louis, and another canal now connects the Rhone with Marseilles.

The littoral of Provence has no great fertility, and, except the stony or marshy plains in the neighbourhood of the Rhone, there is but a narrow strip of land left between the mountains and the sea-coast, which is utilised for vineyards and fruit-gardens; but the remarkably well-sheltered harbours of Marseilles (q.v.), Toulon, Hyères, and St Tropez give birth to a considerable maritime commerce; and Marseilles is the chief port of France for intercourse with the South and East. The eastern part of the coast, acquired from Italy in 1860, is well known for its mild climate and rich vegetation, which render Nice, Villefranche, Cannes, and Mentone the chief resort of the invalids of Europe. As to the western part of the Mediterranean coast—Languedoc—with its cities Montpellier (and its seaport Cette), Carcassonne, Perpignan, Béziers, and Narbonne, its vineyards supply France with abundance of *vin ordinaire*. Finally, the Roussillon, which comprises the eastern outspurs of the Pyrenees, partakes of the character of the Iberian peninsula, especially of Catalonia.

Climate.—France enjoys on the whole a very fine climate; not so continental as that of central Europe, and not so maritime as that of England. Apart from the lofty tracts of the Alps and Pyrenees, the coldest region of France is evidently that of the high plateau with its severe winters, though it has hot summer days. The north-eastern part of the country (Champagne, Alsace, Lorraine, the Vosges) has a continental climate much like that of central Europe. Frosts are recorded there from seventy to ninety days per year, but the amount of snow is seldom considerable in the plains. The Paris basin has a climate transitional between the above and that of the sea-coasts. The mean temperature in December and January is not lower than 37° F.; the spring is beautiful, and excessive heat does not last long during the summer. The annual rainfall is but 21 inches (the average for France is 31.5 inches), and, though it rains on 175 days in the year, the rains usually are of short duration. The climate of Brittany is very much like that of the south-west of England; that of the plains on the Bay of Biscay is warm and dry, and Pau, on the slopes of the Pyrenees, has the deserved reputation of a sanitary station. The region about Lyons has an intermediate, rather wet climate, with cold winter and hot but humid summer; while the climate of Languedoc and Provence assumes to some extent an African character—a mild winter is succeeded by a burning hot, dry summer, moderated from time to time by the *mistral*, which blows violently from the Cévennes, throwing back to the sea the moistness which otherwise might result in rain, so that Marseilles has but fifty-five rainy days during the year. Brest, with a mean of over 44° in winter, and under 65° in summer, has the least seasonal variation of temperature in France. (The corresponding figures for Nancy in the north-east are 34° and 68°; for Perpignan in the south, 45° and 75°.)

Population, Occupations, National Character.—For origins of the French nation and the elements that compose the French population—Celtic Gauls, Belgæ, Aquitanians or Iberians, Romans, Franks and other Germanic tribes, and Normans—see the section below on the history of France, and the separate articles, such as BELGÆ, CELTS, FRANKS, &c. For the dominant language of France, see the section on French Language and Literature. For the Provencal language of the south of France, see that head. In Finistère, Morbihan, and Côtes-du-Nord the Celtic Breton is still the mother-

tongue of 1,200,000 persons, most of whom also speak French (see BRITTANY); and in the south-west the peculiar Basque language is used by 140,000 persons in two arrondissements of the Basses-Pyrénées (see BASQUES). Flemish is spoken by some 150,000 people in French Flanders; the Walloons (q.v.) have their own romance dialect in the north-east of France; and a Germanic patois is spoken in parts of Alsace and Lorraine. As to the national character, it is the sum of so many individual, provincial, and political varieties that a general judgment cannot be pronounced too cautiously. So much, however, can be said, that, like its territory, the French people is a natural transition between the inhabitants of southern Europe and those of the north. It combines the impressionability, the vivacity, the rapidity of conception, and the artistic feeling of the men of the south with the persistence, laboriousness, and rationalism of the men of the north. The sociability of the French has become proverbial.

In 1921 the population of France was 39,209,766, as compared with 39,601,509 in 1911. In the hostilities of 1914-18 France lost 1,354,000 men, and the excess of deaths over births among the civil population was even greater. But for the recovery of Alsace-Lorraine with 1,709,700 inhabitants, the inter-censal decline (1911-21) would have been over 2 millions, as against a gain of 640,000 in 1901-11. In 1866—before the Franco-Prussian war—the population was 38,087,000, so that in half a century the total crept up by little over a million, whereas it jumped from some 20 millions in 1700 to 27½ millions in 1800, and to 35,800,000 in 1851. The main cause of the practically stationary condition of the population for two generations has been the low birth-rate, which, after declining from 31 per thousand in 1800 to 26 in 1860, fell to 20 in 1900. In 1906-10 the birth-rate was 19 per thousand; the death-rate was the same (as against 24 in 1860, 28 in 1800). Of 11,697,000 families in 1911, 3,011,000 had but one child, 2,558,000 only two children, and 1,687,000 none at all. The restriction of births is most pronounced in the agricultural regions of Burgundy, Normandy, Aquitaine, least evident in the industrial centres, fishing communities, and in Savoy.

Emigration (chiefly to Algeria, U.S.A., and Argentine) is trifling—c. 7000 per annum in 1850-1900. Immigration, however, is considerable. In 1921 foreigners in France (mostly Italians, Belgians, Spaniards, and Swiss) numbered 1,550,000—half a million more than in 1901. Migration from country to town has marked the steady growth of industries since the coming of railways. The urban dwellers, who represented only a quarter of the entire population in 1850, accounted for about half the total by 1921. Thus while the population altered little in density in 50 years (184 per square mile in 1921), in distribution it has changed radically. The principal concentrations are in the industrial areas of the north and north-east, on the coasts of Brittany and Normandy, and round the three leading cities. Paris (2,906,000), Marseilles (586,000), and Lyons (562,000) contain over a tenth of the whole population. A dozen other towns—Bordeaux (267,000), Lille (201,000), Nantes, Toulouse, St Etienne, Strasbourg, Le Havre, Nice, Rouen, Roubaix, Nancy, Toulon—have each over 100,000 inhabitants; and there were thirty-three towns in 1921 with from 50,000 to 100,000. The sparsest areas are in the mountainous regions of the Alps, Pyrenees, Massif Central (Lozère, Cantal) and Corsica, the marshy Landes, the barren Crau and the arid Champagne Pouilleuse.

In 1911 fully 56 per cent. of the French people were classed as rural—as compared with 22 per cent. in

England. Of an active population of 20,931,000 (including 7,719,000 women) enumerated in 1911, agriculture and forestry claimed 8,517,000, manufacturing industries 5,746,000, and commerce 2,053,000; transport 1,543,000, public service (army included) 1,292,000, domestic service 929,000, liberal professions 550,000, and mines and quarries 246,000.

Agriculture.—France is still pre-eminently an agricultural country. Half the nation is on the land and supplies the other half with most of its alimentary needs. Exports and imports are not the gauges of national prosperity, as in Britain; the home market is the absorbing concern of the French farmer, as it has been hitherto of the French manufacturer; luxuries—wines and *primeurs*, silks and automobiles—may be sent abroad, but the country uses itself the overwhelming mass of what it produces, normally being self-supplying to a surprising extent.

The system of small holdings, so typical of France, encourages 'Jacques Bonhomme' to work his hardest. Some 3 million people possess or cultivate tiny patches of ground or farms up to 25 acres in extent. Many peasants do not own the land they till, but are *fermiers* (tenant farmers) or *métayers* (who surrender, in lieu of rent, a proportion of the produce to the proprietor); and many are day labourers. An official inquiry made in 1908 showed that in most departments the number of small proprietors was increasing, and since the end of the European War numbers of *métayers* and *fermiers* have been able to purchase the farms they worked. The peasant may be conservative and primitive in many of his ways, but by his patient toil and sheer attachment to the soil he has made the rocky slopes of the Alps and Pyrenees, the swamps and stony deserts of the plains, yield him a livelihood where it seemed impossible for human beings to subsist. Since the Revolution and the breaking up of big estates, private enterprise and state aid have collaborated to raise the value of land; from an average of £8 per acre in 1789 it rose during the 19th century to £27. By chemical and natural manures arable land was improved and crops were doubled or trebled; marshes were drained and made habitable, as in the Landes, the Camargue, the Sologne; territory was won back from encroaching sea and sand; dry stony wastes, as in the Crau, were warped and irrigated into fruitfulness. Crises came and were overcome—*phylloxera* in the 80's and the slump in wine prices in the Midi at the beginning of the 20th century; the competition of grain from North and South America, which led to the introduction in 1892 of protective duties. The Great War, which called the labourer from the harvest-field to the battlefield, and fed the soil of France with hundreds of thousands of its devoted husbandmen, laid waste great areas of the richest agricultural country, maimed and ruined thousands of peasants, and forced the republic to import huge quantities of grain, sugar, and other foodstuffs.

The following table shows the distribution of French territory before and after the War:

	1911. Acres.	1920. Acres
Agricultural and Pastoral Land	98,200,000	99,000,000
Forests	24,700,000	25,500,000
Moor and Unutilized	9,500,000	11,500,000
Total area	132,400,000	136,000,000

The recovery of Alsace-Lorraine added 3,600,000 acres to French territory and made available as fertilisers great deposits of potash; yet the arable land fell from over 59 million acres in 1911 to under 56 millions in 1920, while 2 million acres were added to the uncultivated area. Even then the percentage of land under crops and pasturage

(72.8 of the entire country) is remarkably high. Over two-fifths of French soil is subject to the plough; forests cover nearly 19 per cent., and moor and waste 8.5 of the whole territory.

Crops.—Wheat is the chief grain crop. One-tenth of all France—a land of great white-bread eaters—is given over to wheat. Its ubiquity, however, keeps the average yield comparatively low—19 bushels per acre, as against 30 to 35 in the United Kingdom. The north shows the best results. Oats, like wheat, are grown everywhere. Rye has greatly dwindled since 1840, but persists in the Massif Central and Brittany. The area and produce of the chief crops in 1920 are shown below:

	Acres.	Metric Tons.
Wheat.....	12,532,000	6,448,000
Oats.....	8,474,000	4,280,000
Rye.....	2,146,000	876,000
Barley.....	1,640,000	836,000
Maize.....	847,000	387,000
Buckwheat.....	870,000	370,000
Potatoes.....	3,560,000	1,164,000

Beet-root for sugar and distillation covered 600,000 acres before 1914, but two-thirds of the sugar factories in the north were destroyed in the War, and in 1920 the acreage was only 300,000, and the yield under 3 million metric tons. Flax, which claimed 247,000 acres in 1850, dropped to 70,000 in sixty years. Hemp (in Maine, Anjou, and Brittany) is also disappearing. Hops are grown for beer in the Nord, Côte-d'Or, and Alsace. In certain departments (Dordogne, Lot-et-Garonne, Gironde especially) tobacco, a state monopoly, is authorised (25,000 metric tons before the War). Market-gardening is carried to a fine art, particularly around Paris, in the Midi, Brittany, Anjou, and Picardy. Fruit-growing is widespread, and varies with the climate: apples, pears, and cherries in Normandy and Brittany; peaches, apricots, figs, oranges, lemons, almonds, olives in the south; plums in the Vosges; prunes in Lot-et-Garonne. The central plateau has chestnuts; Dordogne produces walnuts also; Périgord is famed for truffles; Nice and Grasse for flowers.

Viticulture ranks next to wheat-growing in importance, France being the chief wine-producing country in the world. The viticulturists number over 1,500,000; their vineyards extend to nearly 4 million acres; and the yield in 1920 exceeded 1300 million gallons of wine. The Midi—Hérault, Aude, Gard, &c.—accounted for nearly half the quantity (*vin ordinaire*). Bordeaux, Burgundy, Champagne provide *vins de choix*. Only the north-western strip (part of Brittany, Normandy, Picardy, Artois, Flanders) grows no vines. The industry, which is of ancient date, established a record in 1875 with 6,300,000 acres of vines and over 1800 million gallons of wine. Phylloxera and other diseases reduced production in the next decade to a quarter of that total. Replanting with American phylloxera-resisting stocks saved the industry; the average yield was improved, and gradually production approached former figures. Whereas in 1873 fully 88 million gallons of wine were exported, and under 14½ millions imported, in 1920 exports totalled 28 million gallons (worth over 500 million francs), and imports 117 million gallons (valued at under 600 million francs). France imports cheap wine from Algeria, Spain, and Italy, and exports choice wines. Brandy is distilled from wine in many districts—5 million gallons in 1920; the Cognac (q.v.) of the Charentes is world-famed; Armagnac eau-de-vie, produced in Gers and round about, is not so strong. American prohibition, collapse of the German, Russian, and other markets, and high British excise duties told on the wine-grower after the War. See VINE, WINE, BRANDY.

Cider (q.v.) and perry take the place of wine in Normandy, Brittany, and Maine. In good years,

like 1913 and 1915, from 600 to 700 million gallons have been produced in France, the north-west contributing over two-thirds.

Live-stock.—The numbers of farm animals before and after the European War were:

	1913.	1920
Horses.....	2,281,000	2,685,000
Mules.....	193,000	181,000
Asses.....	360,000	288,000
Cattle.....	14,807,000	18,217,000
Sheep.....	16,218,000	9,406,000
Pigs.....	7,048,000	4,942,000
Goats.....	1,458,000	1,841,000

Thus, despite the addition of Alsace-Lorraine, the totals two years after the armistice were in every case still well below the figures for 1913, when the pastoral industries were flourishing and France was exporting horses, cattle, and pigs. Horses are reared especially in the west, among the best-known breeds being the Percheron—sturdy, but far from slow; the heavy draught Boulonnais, the cross-bred Anglo-Norman, and the little Tarbes steed with Arab blood. Poitou is noted for donkeys and mules. Cattle find good pasturage throughout the north-west, in the Auvergne plateau, Burgundy, Jura, among other parts. The chief race is the Norman, both its milk and its meat being excellent. Among draught oxen the white Charolais is in high repute. The dairy industry is most developed in Normandy, Brittany, and the north. Cheese, a *sine qua non* in France, is of infinite variety. Camembert (Normandy), Gruyère (Jura), and delicate Brie are made from cow's milk; Roquefort from ewe's milk (west of the Cévennes and from Corsica). See CHEESE. Unlike cattle, sheep fell in numbers during last century, foreign competition being too strong. The flocks in 1840 were almost double the 1913 total. The best mutton—*pré salé*—comes from the coast of Brittany and Poitou. The largest flocks are in the centre, south, and west, where the pasturage is inadequate for bigger stock, and the climate not too cold and damp—Cévennes, Corsica, Basses-Pyrénées, Aveyron, Bouches-du-Rhône, Berry, and Champagne.

Forests.—Forests and woods extended over 10,328,000 hectares in 1920 (about a third belonging to the state or local authorities), Alsace-Lorraine having added 440,000 hectares. The public forests are subject to a provident régime; but reckless cutting, disastrous fires, and the wholesale destruction and demands of war have made great gaps in many forested regions, and 550,000 hectares were rendered unproductive for years. The greatest forests are in the departments of Landes (516,000 hectares) and Gironde (462,000 hectares), where a wilderness of sand and stagnant pools has been transformed by drainage and pine plantations. The Ardennes, Argonne, and Vosges forests were in the war zone. Round Paris are the fine forests of Fontainebleau, Rambouillet, Orléans, &c. Many slopes of the Alps, Jura, and Pyrenees are pine-clad, and there are large forest areas between Toulon and Cannes (Monts des Maures and Esterel), in the Morvan (Côte-d'Or, Nièvre, &c.), and Dordogne (chestnuts). Mulberries are grown in the lower Rhone valley, where some 50,000 sericulturists (90,000 in 1913) rear silkworms, producing 2000 to 3000 metric tons of cocoons. See FORESTRY.

Mining.—Before the War of 1914-18 France was relatively poor in minerals. Two-thirds of the country's coal and nine-tenths of its iron were produced in the area overrun by the Germans, and the invaders temporarily or permanently put out of service many mines and works. In the centre and other regions the metallurgical industry was, however, greatly stimulated; the restoration of Alsace-Lorraine made France the leading iron-producing country in Europe; and fuel difficulties were met by the exploitation of the Saar coal-mines (see

SAAR), and by the rapid development of hydro-electric power. The production of coal in 1913 was 40 million metric tons, and the consumption over 60 million. The Nord and Pas-de-Calais mines contributed two-thirds of the production. Other coal-fields are in the Loire (St Etienne), Saône-et-Loire (Blanz), Gard (Alais), Tarn, and Aveyron departments; in Bouches-du-Rhône lignite is worked. Between 1873 and 1913 the production of iron ore was raised from 3 to 22 million tons, all but 2 millions from Meurthe-et-Moselle (Briey, Longwy, Nancy). The rest of Lorraine, lost to France in 1871-1918, gave in 1913 over 21 million tons, so that its recovery instantly doubled the iron resources of the republic, and opened up great possibilities for the metallurgical industry (given an adequate supply of fuel). Lorraine ore yields 33 to 40 per cent. of iron; rich deposits, exploited since 1900 in Normandy, Brittany, and Anjou, yield 40 to 60 per cent.; and 'pure' mineral has long been worked in the Pyrenees.

There are valuable antimony mines in Vendée, and aluminium is extracted from the bauxite plentiful in Provence. Small quantities of gold, silver, zinc, lead, copper, manganese, and wolfram are obtained. France is rich in building materials (stone, gravel, slate, cement), witness her cities and roads. Asphalt, bituminous schists, petrol (Alsace), graphite (Hautes-Alpes), and kaolin are also worked. Rock-salt is exploited in Lorraine and elsewhere, and sea-salt in the marshes of the Midi. The unrivalled potash beds (discovered in 1904) in Alsace are invaluable alike to the chemical and agricultural industries. Mineral springs of great variety and fame abound—at Aix-les-Bains, Vichy, Evian and other resorts.

Manufactures.—Industrial development was later and slower in asserting itself than in England, handicaps being shortage of labour and fuel, dearth of machinery and transport. The War of 1914-18, which played havoc with France's main industrial areas, the north and north-east, led to the establishment of new industries (chemical, for instance), and the extension of old ones (especially metallurgy), the expansion of other industrial centres in the heart of the country, and the exploitation of vast resources of neglected water-power; and it gave valuable lessons in mass production and combination. French manufactures, as a rule, have been noted abroad for their artistic taste, novelty, and skilled workmanship, their quality rather than their quantity. The chief industry in France is the manufacture of *textiles*—silks, cotton, wool, linen—which before the War gave employment to about a million workers. Lyons (q.v.) is the centre of the silk industry, but hand-loom in the city itself have given way to power-loom in factories scattered over the Rhône, Isère, and adjoining departments. St Etienne specialises in silk ribbon. Artificial silk is made at Besançon and elsewhere. In 1913, an exceptionally good year, France imported 7½ million kilos of raw silk (from Japan, China, Italy, &c.), and herself produced half a million; she exported silk and silk thread to the value of over £25,000,000 (Britain taking more than a third), and kept £10,000,000 worth for the home market. See **SILK**.

Before the War France imported 330,000 metric tons of raw cotton, and, with over 7½ million spindles and 167,000 hands, exported 64,000 tons of cotton material and thread. Most of the cotton spinning and weaving towns (Lille, Amiens, Roubaix, St Quentin, among others) were in the invaded area, and the industry suffered accordingly. The restoration of Alsace made the Vosges region the principal centre, others being Rouen and Roanne. See **COTTON**.

The flourishing wool industry quartered in the

north (Roubaix, Tourcoing, Fourmies, Avesnes, Cambrai, Reims, &c.) was almost wiped out during hostilities. In 1913, over 268,000 metric tons of wool were imported from Australia, Argentine, and other countries, and added to 35,000 tons of French wool; and 38,000 tons of woollen manufactures were exported. The destruction and stripping of the wool factories in the north gave an impetus to those in Normandy (Elbeuf, Louviers), Languedoc (Mazamet, Castres), Vienne, and round Lyons. Alsace added half a million spindles to the three millions already engaged in wool-spinning. See **WOOL**.

Linen was made at Lille, Cambrai, Armentières, and other parts of the invaded area, mostly from Russian flax, and the industry was therefore very severely hit by the War, the more so as over half the home-grown flax came from the Lys region. Spindles, which numbered 570,000 in 1913, were reduced to one-tenth of that number by 1918. Other industries of the kind are hemp (rope-walks at Angers), jute (Dunkirk), and lace (Caudry, Calais, Le Puy, Luxeuil, Alençon, &c.).

Notwithstanding the destruction of furnaces in the devastated north and north-east, France after the War had over 100,000 men employed in *iron and steel* foundries, and the annual output of cast-iron and steel by 1920-21 was two-thirds of the 1913 totals of 5,207,000 and 4,687,000 metric tons respectively. The foundries are mostly situated beside the Lorraine iron mines, and where coal or water-power is available—in the Nord, St Etienne (Loire), and Le Creusot (Saône-et-Loire), Dauphiné, and Savoy. Alpine streams are also harnessed for the extraction of aluminium, of which France is one of the leading producers. The electrical industry (dynamoes, electric fittings, telephones, &c.) has advanced rapidly during the present century. Subsidiary industries of ever-growing importance are the manufacture of automobiles (over 500 factories, 100,000 hands, and 60,000 cars in 1913), and aeroplane-building.

The chemical industry in all its branches—from picric acid to perfumery—was suddenly stimulated when the War cut off German supplies and created an unprecedented demand for explosives, &c. This industry has greatly profited by the development of hydro-electric power in the Alps, Pyrenees, and Rhone valley. Lyons (artificial dyes) and Marseilles (sulphur, soap) are among the chemical centres. Alimentary industries—besides those already mentioned under agriculture—include macaroni and fainaceous pastes, biscuits, chocolate, coffee, confectionery, olive oil, and liqueurs. Among a host of secondary manufactures may be mentioned clothing and underclothing (Paris fashions), furs, gloves (Grenoble); paper, rubber, glass, porcelain (Limoges, Sèvres), clocks, jewellery, carpets, fans, feathers, and *articles de Paris*.

Fisheries.—Both the deep sea and coast fisheries are valuable, the principal catches being cod (Newfoundland and Iceland), herring and mackerel (North Sea and coast), sardines and tunny (coast). In 1913 there were 28,000 fishing-boats and 160,000 fishermen; the War halved these figures, but recovery was rapid after 1918, sails giving way to steam and motors. The chief fishery port is Boulogne; others are St Malo (for Newfoundland), La Rochelle, Fécamp (cod and herring), Arcachon (oysters), Douarnenez and adjacent Breton coast towns (sardines). See **FISHERIES**.

Merchant Shipping.—Thanks to new construction, purchases, and taking over of ex-enemy ships, the mercantile marine quickly made good war losses of over a million tons and, with a gross tonnage of 3,300,000 tons in 1922 (as compared with under 2,000,000 in 1914), ranked next to Britain in European steam shipping. (The tonnage of sailing ships was over 500,000.) This still left room for

great expansion, as over 70 per cent. of the 35½ million tons entered and of the 26½ millions cleared at French ports in 1922 was under the British or other foreign flag. The lack of bulky exports for outward cargo has long hampered French shipping. The leading commercial ports are Marseilles, Le Havre, Rouen, and Bordeaux; Cherbourg and Boulogne are the outstanding passenger ports.

Foreign Trade.—France's *commerce extérieur* is, according to British standards, small, considering her internal trade, wealth, and population. Between 1870 and 1900 it stagnated, imports (for home consumption) totalling from £150,000,000 to £200,000,000 per annum, and exports (of home origin) seldom reaching the former figure. A high protective tariff was introduced in 1892. The 20th century witnessed a marked improvement, and by 1913 imports reached 336 millions, exports 275 millions sterling. The War naturally inflated imports and restricted exports. In 1915–20 imports averaged 28 milliards (i.e. 28,000 millions) of francs, and exports only 10 milliards. By 1921, however, allowance being made for depreciation of the franc, the values of French imports (23½ milliards) and exports (21½ milliards) were approaching the 1913 standard. In 1913 the tonnage of imports was 44 million metric tons, of exports 22 millions; in 1921 the corresponding figures were 38 millions and 16 millions. The chief exports are mostly manufactured articles—silks, cottons, woollens, clothing, automobiles, chemicals, and wines. Imports are mainly raw materials and foodstuffs—wool, cotton, silk, coal, oil seeds, skins, timber, petroleum, rubber, copper, machinery, cereals, wines, and coffee. Britain, U.S.A., Belgium, Germany, and Switzerland are, with the French colonies, France's principal customers and sources of supply. The United Kingdom has long been the foremost participator in French foreign trade, *inter alia* selling coal, machinery, metals, woollens, cotton yarn, and buying silk, gloves and clothing, woollen goods, wine, motor-cars. Our exports to and imports from France in 1922 both totalled about 48½ millions sterling.

Communications.—French highways are particularly good, road material being plentiful and geographical conditions favourable. *Routes nationales* of remarkable straightness (over 24,000 miles in length) link Paris, the chief centres, and the frontiers. The State maintains them. About 337,000 miles of district roads are controlled by local authorities. Apart from the state railway (including the old Ouest line), the railways are privately owned; the great companies, whose concessions expire in 1950–60, are the Paris-Lyon-Méditerranée or P.L.M. (the biggest), Orléans, Est, Nord (the richest), Midi, and Alsace-Lorraine; these seven systems total over 25,000 miles. About 7000 miles of inland waterways are utilised; the navigable rivers—Seine, Loire, Saône, Rhone, Rhine, &c.—are joined by canals, as are the Mediterranean and Atlantic; the canal system of the north and north-east is the most highly developed. Air lines connect Paris with London and other capitals, and France with Algeria.—See RAILWAYS, CANALS.

Government and Administration.—Since the overthrow of Napoleon III. on 4th September 1870 France has been under a republican form of government, sanctioned in February 1875 by a constitutional law, which has undergone since but slight modifications. The present constitution remains a mixture of monarchical and republican institutions, and it has steadily maintained its strong and long-established centralisation.

The Revolution abolished the thirty-three *gouvernements* which corresponded in the main with the old provinces of France, and substituted therefor divisions known as *départements*. These take

their names generally from some local river or mountain range, their boundaries being largely artificial; more uniform and manageable in size, and making for national unification, they have yet failed to obliterate provincial traditions. There are 89 such départements (86 in 1871–1918) besides the Territory of Belfort; they are subdivided (1921) into 385 *arrondissements*, 3019 *cantons*, and 37,963 *communes*. Over each département the president appoints a *préfet*, over each *arrondissement* a *sous-préfet*. The prefects are powerful political agents and administrative officers. They represent the government generally within their départements, see to the execution of laws and decrees, exercise surveillance over local authorities and public servants, appoint teachers and many minor functionaries, through their subordinates influence the elections, and in many capacities serve the central power which nominates—and may at pleasure cashier—them. Each département has (besides a consultative nominated *conseil de préfecture*) a general council (*conseil général*), a deliberative body, with at least one member per *canton*, elected for six years. The general council votes the local budget, levies departmental taxes, and has charge of local roads, public buildings, health and charitable institutions. *Conseils d'arrondissement* are likewise elected by manhood suffrage, but are of little importance. The *cantons* have no councils of their own, and are merely territorial subdivisions for electoral, judicial, military, and other administrative purposes. The *communes* (or parishes) range in size from a score of acres to over 300,000 (Arles), in population from 30 to nearly 3,000,000 (Paris); more than half have less than 500 inhabitants. Each elects a *conseil municipal*, which chooses a mayor; he is the mouthpiece of the commune, and also the local agent of the state, which can suspend or dismiss him. Decentralisation is more restricted in the largest cities. Thus Paris has no elected mayor; each of its 20 *arrondissements* has a government nominee as mayor; police matters are under control of a *Préfet de Police*; other municipal matters are subject to the *Préfet de la Seine*—which department extends beyond the city. Both prefects are appointed by government.

Parliament consists of a Chamber of Deputies and a Senate. These unite in *Congrès* every seven years to elect a President of the Republic, whose powers are very wide. As head of the executive he signs treaties, declares war, promulgates laws passed by both houses, appoints functionaries and, with the Senate's consent, can dissolve the Chamber. He chooses the *Président du Conseil* or Premier, who, with his ministry, is responsible before parliament. The Chamber of Deputies meets in the Palais Bourbon, and consists of 584 members (including 6 for Algeria and 10 for the colonies). Aged 25 or over, these are elected for four years by manhood suffrage, in the proportion of one deputy per 75,000 inhabitants. Every male citizen of 21 or more has a vote, unless serving in the army. A law of 1919 combined proportional representation with relics of the old majority system. The constituencies are the départements (the Seine and a few others are subdivided), the old single-member constituencies—the *arrondissements*—having been abandoned, the *scrutin de liste* reintroduced, and the necessity of second ballots minimised. Deputies and senators are paid—15,000 fr. annually, plus 1000 fr. *per mensem* added in 1920. The Senate (which sits in the Palais du Luxembourg) under the Constitution of 1875 contained 300 members, of whom 75 were nominated for life. The last of these life senators died in 1918. A law of 1884 substituted an elected senator for each life senator deceased. The restoration of Alsace-Lorraine added 14 new senators. Three senators represent Algeria and 4 the colonies.

Senators must be at least 40 years of age, and are elected for nine years, one-third of the house retiring every three years. They are elected by indirect 'universal' suffrage, the college of electors consisting in each constituency (department) of the deputies, members of the general council and conseils d'arrondissement, and delegates from the municipal councils of the department.

Justice.—The judicial organisation maintains many traces of its ancient character, and remains a powerful instrument in the hands of the government in political matters. In each canton a justice of the peace (*juge de paix*) decides small civil cases, and, in the *tribunal de simple police*, petty offences or 'contraventions.' More important civil cases go before the *tribunal de première instance* (3 judges) for the department, which, sitting as the *tribunal correctionnel*, also punishes more serious infractions of the law (*délits*). Cases of crime proper are tried by a *cour d'assises* (3 judges and a jury of 12 citizens) in the capital of the department. There are 26 appeal courts in Paris and the provinces. In the larger centres commercial disputes are settled by a *tribunal de commerce*; labour disputes are referred to *conseils de prud'hommes*, on which employers and workmen are represented. The Court of Cassation (q.v.) in Paris, on appeal, can quash the judgments of the civil and criminal courts. The *Conseil d'État*, a consultative body of life-members who give the government advice on questions of legislation and administration, is also the supreme tribunal for administrative suits, and judges cases between private citizens and the state. The Senate sits as a High Court of Justice to try a president or a minister impeached by the Chamber of Deputies (e.g. M. Malvy in 1918) or any one charged with an attempt against the security of the state (e.g. Boulanger, Déroulède, Caillaux). A distinctive feature of the procedure in criminal cases is the secret and sometimes protracted preliminary investigation by an examining magistrate (*juge d'instruction*), who dismisses the case or sends it to the competent court, where the *procureur* prosecutes for the state. Besides the departmental prisons there are nine central *maisons de force* for prisoners serving over a year, a convict depot at St Martin de Ré, and penal stations in New Caledonia (where deportation ceased in 1896) and French Guiana, for forcats condemned to hard labour or solitary confinement. For French Law, see CODE.

Religion.—Save 1,000,000 Protestants and 100,000 Jews, the French are (in practice or in name) Roman Catholics. The Concordat of 1801, whereby Napoleon fixed the relations between France, the Gallican Church, and the Papal See, was ended in 1903. A law of 1905 separated church and state, which till then had supported financially, in proportion to their numbers, the Roman Catholic, Protestant, Jewish, and (in North Africa) Muslim faiths. The republic ceased to pay salaries to priests and pastors (except army padres) and to recognise or subsidise any form of worship. Churches and religious brotherhoods and sisterhoods were called on to form themselves into *associations cultuelles* (subject to the common law regulating all kinds of associations) in order to retain ecclesiastical property. The Roman Catholic Church refused, Pius X. condemning such associations (in 1924 Pius XI. withdrew the papal prohibition); the Protestant and Jewish Churches complied. Many religious orders had already, by the Associations Law of 1901, been dissolved or exiled, failing state authorisation. Public worship, however, was not interfered with; the same *curés* officiate as before in the parish churches. There are some 31,500 *curés*, assisted by 9000 *vicaires*; 8 cardinals, 17 archbishops, and 70 bishops. Lyons is the metropolis of Catholic France, its archbishop

being 'Primate of the Gauls.' The Protestants belong mostly to Calvinistic or Reformed Churches, especially in the Cévennes and between Nantes and Bordeaux, those in Alsace, Doubs, and Haute-Saône being Lutherans.

Education.—The present system is the outcome of a long struggle between the state and the church for the right of using education as a means for promoting each its own ends. The National Convention in 1794-95 drew up a scheme of public education under state control, to the exclusion of the clergy, but it was never carried out, and under Napoleon education was subjected to the combined influence of church and state. In 1833 the church secured certain privileges, which were extended by the republican governments of 1850 and 1875; thus it had primary and secondary schools of its own, and could confer university degrees. In 1881-82 primary education was made free and compulsory for children of 6 to 13, and in 1886 it was laicised. Church privileges were abolished, and in 1901 convent schools were suppressed.

The Minister of Public Instruction is aided by a Conseil Supérieur. The whole state-aided teaching organisation—primary, secondary, and higher or university—forms the 'University of France.' The country is divided into 16 educational districts called *académies*—viz. Paris, Aix, Besançon, Bordeaux, Caen, Clermont, Dijon, Grenoble (incorporating Chambéry since 1920), Lille, Lyons, Montpellier, Nancy, Poitiers, Rennes, Toulouse, Strasbourg. Each *académie* is administered by a rector, assisted by inspectors (one for each *département*) and an academic council, on which teachers, professors, general and municipal councils are represented. Every commune has at least one elementary primary school. Higher primary schools provide a further three years' course. For infants (up to 6) there are *écoles maternelles*. Secondary education is given in state *lycées*, in communal *colleges*, and in private establishments; *enseignement supérieur* in universities and special colleges, many of which are of high reputation—the Collège de France, Museum of Natural History, École des Hautes Études, École des Chartes, École Normale Supérieure, École Polytechnique and St Cyr (military), Institut Pasteur, Beaux Arts, &c. In 1920 there were 4,690,000 pupils enrolled in elementary schools (19 per cent. in private schools) and 264,000 in *écoles maternelles*. Public secondary schools had 105,000 boys (at 120 *lycées* and 234 *collèges*) and 42,000 girls (64 *lycées*, 83 *collèges*). There are besides many private schools, some taking the place of suppressed clerical institutions. In 1919 only 2 per cent. of conscripts were illiterate. The 16 universities vary greatly in size and in number of faculties, among the most important being Paris; Lyons and Bordeaux (especially medicine); Grenoble and Toulouse (science); Montpellier, Strasbourg, and Nancy. There were 50,000 students in 1921, Paris alone having 21,000. The clergy have their own 'free faculties,' but these cannot confer degrees. See also UNIVERSITY and ACADEMY.

Army.—The army is recruited by compulsory military service. The law of 1872 imposed 5 years with the colours; this was altered to 3 in 1889, 2 in 1905, 3 again in 1913, and 1½ in 1923. All Frenchmen become liable to serve at 20, and remain so for 28 years, active service being followed by 2 years' *disponibilité*, 16½ years in the first reserve and 8 in the second. In 1913 674,000 officers and men were serving; in August 1914 3,781,000 were mobilised; by 1917 over 3 millions were on the western and Macedonian fronts, 1½ millions elsewhere in France or North Africa, besides 1½ million conscripts at munitions, railways, land work, &c. Nearly 10,000,000 men were mobilised in 1914-18 and 1,400,000 killed. After the War the

French army was the most powerful in the world. The peace establishment of the active metropolitan army was 335,000 in 1922, exclusive of 160,000 in the armies of occupation. The Colonial army and North African troops added other 250,000, including 50,000 whites (Foreign Legion, Zouaves, &c.). The native troops (Algerians, Moroccans, Senegalese, &c.) have been greatly increased since 1914. The infantry rifle is the Lebel; the favourite field-gun is the quick-firing '75' (3-inch bore). Uniforms are horizon blue, except for Chasseurs (dark blue) and Colonial troops (khaki). The Gendarmerie is a military police force; the Garde Républicaine a similar body in Paris. See ARMY.

Navy.—The French navy, second only to the British in the 19th century, was outstripped in the 20th by America, Germany, and Japan, and by the Treaty of Washington (1922) was put on an equal footing with Italy in tonnage of capital ships, its replacement tonnage being fixed at 175,000 tons. France had then 10 battleships (7 of them Dreadnoughts). After the War the fleet was strongly reinforced by light vessels for defence purposes. (See NAVY.) The navy is recruited partly by voluntary enlistment, partly by conscription. The coasts are divided into five maritime arrondissements, under *préfets maritimes*, with headquarters at the chief naval ports, viz. Brest, Cherbourg, Toulon, Lorient, Rochefort.

Finances.—The Constituante in 1790 abolished the old one-sided oppressive taxation and levied various *contributions*, relying disproportionately on indirect taxation for revenue purposes. This régime held till the European War, on the eve of which an income-tax act was passed (July 1914). Before then the direct contributions were on (1) land (built and unbuilt); (2) personal property (based on rent); (3) doors and windows; and (4) *patentes* or trade licences—the state taking about half the proceeds and the departments and communes the rest. The last three were abolished, so far as the state was concerned, in 1917, when the income-tax was extended. Commercial and industrial profits are now taxed, as also turnover. Indirect taxation includes registration, stamp, customs and excise duties. A municipal indirect tax, the *Octroi* (q.v.) also brings in large sums. Other rich sources of revenue are state monopolies (tobacco, matches, gunpowder), posts and telegraphs, and state domains (forests, &c.). In 1913 direct taxation accounted for 11 per cent. of the 5100 million francs collected (expenditure being 6000 millions); in 1919 it contributed 2253 million francs—about 20 per cent. of the total receipts. The 1923 budget calculated revenue at 19,285 million francs, and expenditure nearly 4000 millions more.

The French national debt rose from £51,000,000 in 1815 to £498,000,000 in 1870, when war expenses and indemnity added 40 millions sterling. In July 1914 it was 34,188 million francs; by the end of hostilities (January 1919) it was 151,100 millions; and by 1922, thanks to reparations of the devastated areas, &c., 317,000 million francs (£12,679,000,000 at par of exchange, or over £323 per head of the population). Of this total, foreign debt (nil in July 1914) represented 75,000 million francs.

For further information see (in addition to the modern histories mentioned on a later page) geographical works by E. and O. Reclus, Vidal de la Blache, Ardouin-Dumazet and Joanne; Fallex and Mairey, *La France et ses Colonies* (1922); *Un Demi-Siècle de Civilisation Française* (1916) by various hands; E. Barthélemy, *Le Gouvernement de la France* (1919); the *Annuaire Statistique* and the *Annuaire Général de la France et de l'Étranger*; books on the Colonies by H. Lorin, P. Gaffarel, and M. Petit, and *L'Annuaire Colonial*; Bodley's *France*, and volumes by Miss Betham

Edwards and A. J. C. Hare. See also EUROPE (for geology); BRITANNY, NORMANDY, and other provinces; PARIS, LYONS, MARSEILLES; SAÏNE, RHONE, LOIRE; ALPS, PYRENEES; and for French money, weights and measures, FRANC, METRE, LITRE, GRAMME, DECIMAL SYSTEM.

HISTORY.—At the dawn of history what is now France was occupied by a multiplicity of tribes, belonging to several different races; but the Celtic Gauls were the dominant people, and held the greater part of the country. The Ligurians occupied the Mediterranean shores; the Iberians or Basques held the south-west; and in the north-east were the Belgæ, Germanic immigrants who had adopted a Celtic tongue, or Celts who had been in some respects Germanised or mixed with Germans. The Gauls were sufficiently energetic to have conquered North Italy and terrorised Rome from the 6th century B.C. to the middle of the 3d century B.C., and even pushed victorious armies into Thrace and Galatia. But the Romans conquered the Cisalpine Gauls about 225 B.C., and by 150 had conquered the south of Transalpine Gaul (Provence); in 58–50 B.C. Julius Cæsar conquered the sixty-four different states in Gaul, and from that time the Gauls rapidly adopted the Roman polity, the Latin speech, and Roman manners. Greek civilisation had ere this gained a footing at Massilia (Marseilles), but history for France, as for Great Britain and Spain, began with the Roman Conquest. Protected against Teutonic invasion by military posts on the Rhine, subjected for the first time to legislation and administration, the Gallic tribes, who had risen before their conquest to the height of civilisation attainable by them without foreign aid, turned to peaceful pursuits, such as agriculture and commerce, and built for their governors amphitheatres, public baths, aqueducts, military roads. Lugdunum (Lyons) became a Transalpine Rome. In the 2d century A.D. Gaul was the most populous, in the 4th it was one of the most civilised Roman provinces. Its schools were so famous that Roman-born students went to learn there the art of eloquence. Its nobles and cultured classes supplied the empire with more than one general and with more than one poet or prose-writer. It became the home of an enlightened Christianity, but did not escape the rebellions of slaves and land-labourers which broke out now and then in the empire, and bore witness to aristocratic and ecclesiastic oppression. Thus, by the engrafting of Roman civilisation upon the old Celtic stock, there grew between the Alps, the Mediterranean, the Pyrenees, the Atlantic, and the Rhine a Gallo-Roman state, with a culture free from the Hellenistic stamp peculiar to the eastern provinces of the empire, and more akin in many respects to our modern circumstances than to those of the ancient world. Indeed, Gaul was fast being elaborated into a pure neo-Latin nationality, when, from the year 395 onward, the Teutonic tribes, pent up to the east of the Rhine, and pressed from behind by Slavonic hordes, burst upon the scene and acted as a dissolvent upon Roman civilisation. Beaten in Tuscany in 406, bands of Vandals, Burgundians, Suevi, and Alemanni, falling back upon Gaul left bare of troops, destroyed the forts on the Rhine and in the interior of the country. After long wanderings the Burgundians settled in the fruitful plains of the Rhone valley, and founded the kingdom of Burgundy from the Mediterranean border to the Vosges. A few years later the Goths, also retreating from Italy, occupied both sides of the Pyrenees, founding the kingdom of the Visigoths, from the Garonne in the north to the Ebro in the south, with its capital at Toulouse. In 451 a Roman general of barbarian birth, Aetius (q.v.), fighting at the head of an army in which Romans, Burgundians, and Visigoths stood

side by side, defeated in the Catalaunian fields (Châlons-sur-Marne) the hordes of Attila. This was Rome's last deed of war in Gaul.

The staff of military supremacy fell from the hands of the Romans into those of the Franks. These were a confederacy of the Germanic tribes between the Rhine and the Harz Mountains, whom the Romans had attacked in vain, and to whose persistent invasions they had to sacrifice Belgium. Once in possession of the banks of the Meuse and of the Sambre, they advanced under their king Clovis (481-511) towards the Seine and the Loire, and made at first Soissons and then Paris their capital. Clovis became a Christian. Carving out for himself a realm abutting to the south upon the Visigoths, and to the east and south-east upon the Burgundians, he laid, from the Rhone and Garonne to Brittany, foundations for the future kingdom of France. Clovis, through his zeal in the interests of the Catholic Church, earned the title of 'most Christian king,' which passed from the Frankish chiefs to the kings of France. The emperor at Constantinople gave him the Roman title of patrician and consul. The Franks remained subject to their own 'Salic law,' but they maintained in Gaul Roman law, Roman state and church organisation. Thus a Germanic tribe became the leading military and political agent in the plains of northern Gaul, and gave to France its name and its first dynasty of kings, the Merovingians (q.v.); but it adopted the Romance tongue of the conquered. Charles Martel, *maire du palais* to the 'Rois Fainéants,' defeated Arab invaders at Poitiers (732) and drove them south.

In 752 the Karlings or Carolingians (q.v.), in the person of Pepin the Short, superseded the Merovingian dynasty, and laid the foundation of the temporal power of the popes. Pepin's son, Charlemagne (768-814), raised to its zenith the supremacy of the Franks in western Europe, by uniting under his hegemony the Germanic states hewn out of the Roman provinces. Coming at a time when the Germanic ruling classes were no longer separable from the conquered masses, the formal centralisation of power in his hands, ratified by his coronation in 800 as Roman emperor by the pope Leo III., could not long stem the forces at work for the splitting up of western Europe into a number of small states; neither could this result be accomplished by the building up of a military monarchy extending from the Ebro in Spain, and from the Apennines in Italy, to the North Sea, and from the Atlantic to the Elbe in Germany, the establishment of a code of imperial law and of a system of imperial government, the encouragement of learning and commerce. The Frankish military hegemony fell to the ground under the reign of his weak successors. The next step towards the formation of France was the Treaty of Verdun (843), by which the localisation of the Germans became final; their former racial unity sank in an awakening sense of different nationalities.

Feudal Monarchy.—Though Charles the Simple was politic enough to put an end to the incursions of the Normans by making their leader Rollo Duke of Normandy, the unchecked development of a hereditary aristocracy had reduced the royal power to a shadow, when in 987 Hugh Capet, Count of Paris and of Orleans, was made king by the feudal chiefs. He was the real founder of the French monarchy as distinct from the extinguished Frankish kingship, and from the imperial dignity which was vested after Charlemagne in the ruling house of Germany. While the Roman emperors of the German nation often took up their abode at Aix-la-Chapelle, Charlemagne's residence, the Capetian kings, residing in Paris and crowned in Rheims, became an outward sign that the Rhine divided races again, as in the days of Varus and Arminius

(q.v.). Louis *le Gros* (1108-37) regulated the feudal system, abolished serfdom on his own estates, secured corporate rights to the cities under his jurisdiction, while a new element in the state was generated by the foundation of a free burgher class. At this juncture the policy of the Plantagenets forced England into hostility with France. Henry of Anjou, already Duke of Normandy, suzerain lord of Brittany, Count of Maine and Touraine, had married Eleanor of Aquitaine, who brought him the provinces of Guienne, Poitou, and Gascony; and when in 1124 he became king of England as Henry II. (q.v.), his prestige outshone utterly the French court. The kings of England laid claim to the crown of France; the French kings demanded obedience from their too powerful vassals. Hence an enmity so persistent, and fed subsequently from so many sources, that the Crusades, of which the Normans were the most zealous promoters, offer the only instances of military fellowship between England and France till the days of the Crimean war. Philippe Auguste (1180-1223) recovered Normandy, Maine, Touraine, and Poitou from John of England. He took an active personal share in the Crusades, and permitted the pope to organise a cruel persecution against the Albigenses in the southern parts of the country. Philippe was the first to levy a tax for the maintenance of a standing army, and in his reign a chamber of peers, of six secular and six ecclesiastical members, was instituted to act as a council of state. Many noble institutions date their origin from this reign, as the university of Paris, the Louvre, &c. A right of appeal to the royal courts was established, and the arbitrary power of the great vassals crippled. Improvements in the mode of administering the law were continued under his son, and his grandson, Louis IX. (1226-70), who, before his departure for the Crusades, secured the rights of the Gallican Church by a special statute, in order to counteract the constant encroachments of the papal power. Under his son, Philippe III. (1270-85), titles of nobility were first conferred by letters-patent. He added Valois and the *comtés* of Toulouse and Venaissin to the crown. Philippe IV. (1285-1314), surnamed *le Bel*, acquired Navarre, Champagne, and Brié by marriage. With the object of securing support against the secular and ecclesiastical nobility, Philippe gave prominence to the burgher element in the nation, and for the first time called together the *États Généraux*, or States General, at which the *tiers état*, or burgher class, appeared together with the nobles and clergy. With the view of securing to the crown the great fiefs, he abrogated the right of females to succeed to landed property. His tyrannical persecution of the Templars showed his abuse of the regal power, while the transference of the holy see to Avignon brought the popes for seventy years under the influence of the French court. Under his three sons and successors, Louis X. (1314-16), Philippe V. (1316-22), and Charles IV., *le Bel* (1322-28), the rule of the kings of France was strengthened and extended.

House of Valois.—Philippe VI. (1328-50), the first of the House of Valois, succeeded in right of the Salic law. His reign, and those of his successors, John (1350-64) and Charles V., *le Sage* (1364-80), were disturbed by constant wars with Edward III. of England, who laid claim to the throne in right of his mother, a daughter of Philippe *le Bel*. The war began in 1339; in 1346 the battle of Crécy was fought; at the battle of Poitiers (1356) John was made captive; and before its final close, after the death of Edward (1377), the state was reduced to bankruptcy, the nobility excited to rebellion, and the mass of the people sunk in barbarism. Debasement of the coinage,

onerous taxation, and arbitrary conscriptions brought the country to the verge of irretrievable ruin, while the victories of England humbled the sovereign, annihilated the French armies, and cut down the flower of the nation. The long and weak minority of Richard II. diverted the English from the prosecution of their groundless claims to the kingdom of France; but during the minority of Charles VI., *le Bien Aimé* (1380-1422), the war was renewed with increased vigour on the part of the English nation, who were stimulated by the daring valour of Henry V. The signal victory won by the English at Agincourt in 1415; the treason and rebellion of the French princes of the blood, who governed the larger provinces; the ambition of the several regents, the ultimate imbecility of the king, the profligacy of his queen, and the love of pleasure early evinced by the dauphin; all combined to aid Henry in his attempts upon the throne. But the premature death of Henry, the persevering spirit of the people, and the extraordinary influence exercised over her countrymen by the Maid of Orleans concurred in bringing about a thorough reaction, and, after a period of murder, rapine, and anarchy, Charles VII., *le Victorieux* (1422-61), was crowned at Rheims. He obtained from the States General a regular tax (*taille*) for the maintenance of paid soldiers, to keep in check the mercenaries and marauders who pillaged the country. The policy of his successor, Louis XI. (1461-83), favoured the burgher and trading classes at the expense of the nobles, while he humbled the power of the vassal princes. He was a crafty ruler, who managed the finances well, and succeeded in recovering for the crown the territories of Maine, Anjou, and Provence; while he made himself master of some portions of the territories of Charles the Bold, Duke of Burgundy. Charles VIII. (1483-98), by his marriage with Anne of Brittany, secured that powerful state, and consolidated the increasing power of the crown. With him ended the direct male succession of the House of Valois.

Louis XII., *le Pere du Peuple* (1498-1515), was the only representative of the *Valois-Orléans* family. The tendency of his reign was to confirm the regal supremacy, while the general condition of the people was ameliorated. He and his successor, Francis I. (1515-47) of the *Valois-Angoulême* branch, wasted their resources in futile attempts to establish their hereditary claims to Lombardy. Francis I.'s rivalry with the Emperor Charles V. of Spain gave itself vent in four wars for the possession of Burgundy and Italy. Knighted by Bayard (q.v.) after the victory of Maignan (1515), but defeated and taken prisoner at Pavia (1525), Francis ultimately had to renounce Italy, though he made good his title to Burgundy (1544). His reign is marked by the flowering of the Renaissance, by the beginning of the Protestant Reformation and work of Calvin (q.v.), by the further strengthening of the absolute power of the monarchy, and by the subordination of the clergy to the crown in terms of the 'Concordat' signed with the pope. An ally of the Protestant princes in Germany, and of the schismatic king of England, Henry VIII., he yet remained in his home policy an adherent of the Roman Catholic religion. He and his immediate successors were concerned mainly with the political aspects of the Reformation, which recruited its upholders from the aristocratic and enlightened classes. Henri II. (1547-59) recovered Calais for France. Under Francis II. (1559-60) the Roman Catholic House of Guise obtained possession of the effective power in the state. Their adversaries, the House of Bourbon, headed the movement of the 'Réforme.' Under the weak kings Charles IX. (1560-74) and Henri III. (1574-89), who were under

the influence of their mother, Catharine de' Medici, this division in the French nobility resulted in wars of religion and the war of the League. The massacre of Protestants on the night of St Bartholomew (1572) so raised the pride of the House of Guise that eventually Henri III. fled to the Bourbon camp, where, in 1589, he was murdered by a fanatical monk. The name of Charles IX. remains associated with the horrors of the St Bartholomew's night, which witnessed the striking of a blow at the very heart of the nation; the first step in a periodical recourse to murder, persecution, and proscription. Such horrors, renewed by Louis XIV. against the Protestants, and applied by the Revolution to a different class, have, with the triumphant campaigns of Napoleon, done more to weaken France than the worst blows of its enemies.

Bourbon Line.—The accession of the Bourbon prince, Henri IV. of Navarre (1589-1610), allayed the fury of religious wars, but his recantation of Protestantism in favour of Catholicism disappointed his own party, to which, however, he granted the free exercise of their religion and ecclesiastic autonomy by the Edict of Nantes (1598). By degrees Henri, through the counsels of his minister Sully, and by his own personal popularity, raised the power of the crown higher than ever, while he began a system of thorough administrative reform, which was arrested only by his assassination by the fanatic Ravallac. During the reign of his son, Louis XIII. (1610-43), Cardinal Richelieu, one of the greatest statesmen of modern Europe, resumed the policy of Francis I. against the House of Hapsburg by entering into a compact with the Protestant princes engaged in the Thirty Years' War, raised higher the authority of the crown at home, and humbled the Huguenots, who in the south and west of France had established almost a state within the state. Cardinal Mazarin, under the regency of the queen-mother, Anne of Austria, governed during the minority of Louis XIV. His continuation of Richelieu's policy roused the parliament of Paris to a last effort in favour of its ancient political liberties, systematically cut down or ignored by the kings; the nobility also made a last stand for their feudal rights. The civil war of the Fronde ensued (1648-53). Its termination put all classes under the heel of the young king, Louis XIV. (1643-1715), who could justly say, with local parliaments reduced to judicial and administrative bodies, with aristocrats demeaned into courtiers, 'L'état, c'est moi.' During his reign the French monarchy culminated. But under a cloak of magnificence, sores gathered sufficient to effect its ruin less than seventy-five years after his death. He continued the policy of Richelieu and Mazarin. The successes of his armies under Condé, Turenne, Vauban, Luxembourg, Catinat, Vendôme, Boufflers, and Créqui extended the boundaries of France to the Rhine, and to Flanders in the north; this was mainly due to the talent of Louvois in developing the military and naval resources of France, and to the financial skill of Colbert. But the war of the Spanish Succession (1701-14), though confirming a prince of the House of Bourbon upon the Spanish throne, ended disastrously for the French, repeatedly defeated by Prince Eugene of Savoy and Marlborough. At home the greatest splendour and luxury were displayed; art, literature, and science flourished to a degree unknown before. The proud king compelled the pope to restore to the Gallican Church some of its privileges, but he fell under the influence of Jesuit advisers, and dealt his country a baneful blow by the revocation of the Edict of Nantes (1685), causing 400,000 Protestants to emigrate. At the close of his rule, his absolutism and

bigotry, the oppressive war-taxes, the prodigality of the court, and the luxurious lives of the clergy bore their fruit.

His youthful heir, Louis XV. (1715-74), succeeded to a heritage whose glory was tarnished, and whose stability was shaken to its very foundations. The long reign of Louis XV. presents nothing worthy of notice except the gradual rise of those modern philosophical and political sentiments which prepared the overthrow of all the ancient institutions of the country. The regency of the profligate Orleans paved the way for the miseries which followed, while his corrupt financial administration brought the nation into the most overwhelming financial embarrassments. In this reign Corsica was added to France. The state was thoroughly disorganised, the fleet and army neglected. The colonies fell a prey to foreign attacks; the work of Champlain in Canada (1608-35), of Duplex in India (1730-53), was undone; while the capricious change of policy which the king's mistress, Madame de Pompadour, forced upon the government brought contempt on the country. The Peace of Paris (1763), by which the greater portion of the colonial possessions of France were given up to England, terminated an inglorious war, in which the French had expended 1350 millions of francs. The close of this unhappy reign was still further disturbed by the cabals of the Jesuits, but their banishment in 1764 marked the triumph of the philosophic movement over the Roman Catholic Church. In 1774 Louis XVI., a well-meaning, weak prince, succeeded to the throne. His first ministers, Maurepas, Turgot, and Malesherbes, had not the vigour to carry out reforms. They were succeeded by the financier Necker, who endeavoured, by economy and method, to arrest the impending bankruptcy of the state. The influence of Voltaire, Rousseau, Montesquieu, and a host of other writers imbued with the modern democratic spirit, the sufferings of the masses, the importation of English political ideas, the American war of independence, in which the French took an important part (in pursuance of a deliberate design in this way most effectually to weaken England), the restoration to the Paris and provincial parliaments of some of their long-lost privileges, conspired together to sound the death-knell of monarchical absolutism. After much opposition on the part of the king and court, the States General, which had not met since 1614, assembled at Versailles on the 5th of May 1789. They formed themselves into a *National Assembly*, thereby commencing the Revolution, and undertaking to make a new constitution, they presently called themselves the *Constituent Assembly*.

The Revolution.—Under the 'ancien régime' thus abruptly brought to an end the grades of nobility had become so numerous that their members stood in the ratio of 1 to 250 of the entire population. Nevertheless, every grade of nobility exempted its holder from the payment of the ordinary land-tax or *taille*, from the charge of maintaining the public roads (*corvée*), from military conscription, from receiving billets of soldiers, &c. The nobles paid the *capitation* tax, but in a very unequal proportion, although the landed property was vested almost entirely in their hands. They, in fact, together with the clergy, monopolised the principal share of the national revenues, and left to the lower classes the burden of labour and of paying the taxes. At the outbreak of the Revolution the French nobility were sunk in profligacy and fallen to the lowest stage of demoralisation. The clergy kept pace with the nobles in general depravity, and while their aggregate revenues amounted, according to Necker, to 130,000,000 of livres, and their landed property stood in the

relation of 1 to 5½ of that of all other proprietors, their contributions towards the maintenance of the state were inadequate and irregular. The *tiers état* were crushed by the weight of an unjust taxation, which was rendered more obnoxious by the system of farming out some of the taxes. The most tyrannical of these was the tax (*gabelle*) on salt. The municipal institutions which had been permitted to flourish under some of the Valois princes in the middle ages were almost entirely abolished, and the offices of towns, like those of the state and the courts of justice, were either hereditary or open to purchase. The *tiers état*, which included professional men and all who were not members of either the noble or the clerical order, saw themselves utterly excluded from all participation in the privileges and duties of free citizens at the very time when their minds were drawn to the discussion of questions of political independence, equal rights, and universal freedom.

The resistance made by Louis and his advisers to the reasonable demands of the Deputies led to their declaration of inviolability. The king retaliated by ordering a large body of troops under arms, dissolving his ministry, and banishing Necker, whom he had shortly before recalled under the pressure of public opinion. The consequence was the outbreak of insurrectionary movements at Paris, where blood was shed on the 12th July 1789. On the following day the National Guard of Paris, and a new civic militia under the authority of the municipality were convoked; and on the 14th the people stormed the Bastille. The provinces repeated the acts of Paris, and everywhere national guards and revolutionary municipal councils were called together. On the 4th of August feudal and manorial rights were abrogated by the Assembly, which made a solemn declaration of the equality of human rights. The royal princes and all the nobles who could escape sought safety in flight. The royal family, having attempted in vain to follow their example, tried to conciliate the people by the feigned assumption of republican sentiments; but on the 5th of October the rabble, followed by numbers of the National Guard, attacked Versailles, and compelled the king and his family to remove to Paris, whither the Assembly also moved. The next two years witnessed the solemn inauguration and the subsequent withdrawal of various constitutional schemes. The princes of the blood and the ancient noblesse raised corps of émigrés, but their efforts could not arrest the spread of republicanism. The king alternately made concessions to the republicans, and cherished schemes for escaping from their surveillance; but each month added to his humiliations and to the audacity of those surrounding him. With the death in 1791 of Mirabeau, the champion of the National Assembly, all chance of the establishment of constitutional monarchy perished. The Constituent Assembly was succeeded in 1791 by the *Legislative Assembly*. The king was compelled by the Girondists to a war with Austria in April 1792; and the early defeats of the French were visited on Louis, who was confined in August with his family in the Temple. The advance of the Prussians into Champagne threw Paris into the wildest excitement. The Assembly dissolved itself in September, the *National Convention* took its place, and the republic was proclaimed. In December the king was brought to trial, and called upon to answer for repeated acts of treason against the republic. On the 20th January 1793 sentence of death was passed upon him; and on the following day he was beheaded. Revolts burst out in every part of France. England, Holland, Spain, Naples, and the German states combined together against the republic. Christianity was now formally repudiated, and

the sacredness of the republic and the worship of Reason solemnised. Marie Antoinette, the widowed queen, was guillotined; the dauphin and his surviving relatives suffered every indignity. A reign of blood and terror succeeded. Danton and Robespierre, after having condemned countless numbers to the guillotine, suffered each in turn a similar fate. After the destruction of the Terrorists a reaction gradually set in; the people were wearied of bloodshed and anxious for peace and order at any price. In 1793, 1795, and later, insurrections took place in La Vendée on behalf of the white flag, but were quenched in blood. The brilliant exploits of the young general Napoleon Bonaparte in Italy turned men's thoughts into fresh channels. In 1795 a general amnesty was declared, peace was concluded with Prussia and Spain, and the war was carried on with redoubled vigour against Austria. The Revolution had reached a turning-point.

A *Directory* was formed to administer the government, which was now conducted in a spirit of order and conciliation. In 1797 Bonaparte and his brother-commanders were omnipotent in Italy; Austria was compelled to give up Belgium and recognise the Cisalpine Republic. The glory of the French arms was re-established abroad, but at home the nation was still suffering from the shock of the Revolution. The Directory repudiated two-thirds of the national debt, and thus almost ruined the commerce and credit of France. Under the pretext of attacking England, a fleet of 400 ships and an army of 36,000 picked men were equipped; their destination proved, however, to be Egypt, whither the Directory sent Bonaparte; but the young general, resigning the command to Kléber, landed in France in 1799. The Directory fell on the famous '18th Brumaire' (9th November 1799); under the constitution of Sieyès the state was put under consuls, who, unlike those of Rome, were three in number, with different degrees of authority; Napoleon secured supreme power as First Consul. In 1800 a new constitution was promulgated, vesting the sole executive power in Bonaparte, who showed consummate skill in reorganising the government, to which he imparted a systematic efficiency and a spirit of centralisation that secured a thoroughly practical administration. Having resumed his command, he marched an army over the Alps, attacked the Austrians unawares, and decided the fate of Italy by his victory at Marengo. In 1801 the Peace of Lunéville was concluded, and the boundaries of France were once more extended to the Rhine. England was the only country which refused to recognise the various Italian and German conquests of France; and, with the exception of a brief period of peace, England remained the implacable foe of Bonaparte from the days of the consulate to his defeat at Waterloo. Every period of respite from war was employed by the First Consul in fostering trade and industry, and in obliterating both in private and public life the stains left by the Reign of Terror.

The Empire.—In 1804, on an appeal by universal suffrage to the nation, Bonaparte was proclaimed emperor. The pope came to Paris to crown him and his wife Josephine; a new nobility was rapidly created, and the relatives and favourites of the emperor received vanquished kingdoms and principalities at his hands. For a time Napoleon's influence with the weakened powers of the Continent succeeded in maintaining an injurious system of blockade against England; and, except in the Peninsula, his arms were everywhere victorious. His marriage, too, with the Archduchess Maria Louisa, a direct descendant of the ancient House of Hapsburg (1810), seemed to give to his throne the prestige of birth, which alone it had lacked.

He kept up the democratic impulse of the Revolution as much as was wanted to drive his engine of war. His tactics would have availed him little against the successive European coalitions had he not adopted the principle of national armies, general conscription, and forced requisition introduced by Carnot, the 'organiser' of revolutionary France's victorious resistance against foreign aggression. This principle has since become the outstanding feature of continental warfare. It gave Napoleon an empire including practically the whole of Europe, except Russia, Turkey, and Great Britain; when it was quietly introduced by Prussia, it assisted effectually in bringing to a close the emperor's career, but not until he had made himself king of Italy (1805), made of Holland and Naples vassal kingdoms (1806), set up in Germany the Confederation of the Rhine, conquered Prussia (1806-7), occupied Portugal, deposed the Bourbons in Spain (1808), reduced the Hapsburgs after four campaigns from their mediæval title of Roman emperors to the status of emperors of Austria, made of Rome a French town, and carried off Pope Pius VII. to Fontainebleau. In the long run, the evils attending his high-handed policy both in France and out of it undermined his position. The French navy was destroyed by Nelson at Trafalgar (1805), and the sea-trade of France much injured. His despotism, the unceasing strain of war, the burden of conscription, the estrangement between emperor and pope combined to cause disaffection among the French people.

From 1811 to his final defeat in 1815 the emperor rapidly lost ground. The disastrous Russian campaign, in which his enormous army of 400,000 men was lost amid the rigours of a northern winter, was soon followed by the falling away of his allies and feudatories. Napoleon himself was still victorious wherever he appeared in person, but his generals were beaten in numerous engagements; and the great defeat of Leipzig (1813) compelled the French to retreat beyond the Rhine. The Swedes brought reinforcements to swell the ranks of his enemies on the east frontier, while the English pressed on from the south; the senate and his ministry betrayed his cause, and the allies marched on Paris, which, in the absence of the emperor, capitulated after a short resistance, March 30, 1814. Napoleon now abdicated in favour of his young son, and retired to the island of Elba, the sovereignty of which had been granted to him. His wife and son removed to Vienna; his family were declared to have forfeited the throne; France was reduced to her former limits, and the provinces she had acquired were restored to their national rulers.

The Restoration.—On the 3d May Louis XVIII. (the brother of Louis XVI.) made his entry into Paris. The conduct of the Bourbons did not conciliate the nation; they returned loaded with debts, and surrounded by the old nobility and clergy, who had not renounced their former privileges, and who looked upon the generation of Frenchmen that had arisen since the Revolution as their natural enemies. A narrow spirit influenced the weak policy of the king, which led to the establishment of a strict censorship, the extension of the powers of the police, and the persecution of the adherents of the Empire; while the lower classes and the army, who alike resented the humiliating reaction that had followed the former excitement of war and conquest, were treated with an indifference, and even contempt, by the returned émigrés, to which they were wholly unaccustomed. On the 1st March 1815 Napoleon left Elba and landed in France. The soldiers flocked around his standard; the Bourbons fled, and he took possession of their palaces. The news of his landing spread terror

through Europe; and on the 25th March a treaty of alliance was signed at Vienna between Austria, Russia, Prussia, and England, and preparations were at once made to put down the movement in his favour and restore the Bourbon dynasty. At first the old prestige of success seemed to attend Napoleon; but on the 18th June he was defeated at Waterloo; and, having placed himself under the safeguard of the English, he was sent to the island of St Helena, in conformity with the generally acknowledged sentiment that it was necessary to the peace of Europe to remove him finally and definitely from the scene of his former power.

The second restoration gave occasion to many pledges of a more liberal policy on the part of Louis, but few of them were fulfilled, and a general and sullen discontent reigned among the people, who were again deprived of all voice in the administration or in the election to offices, and were harassed by the petty tyranny of the priests, who were the favourite advisers of the crown. In 1821 Napoleon breathed his last at St Helena; and in 1824 Louis XVIII. died without direct heirs, when his brother, the Duc d'Angoulême, succeeded as Charles X. The same ministerial incapacity, want of good faith, general discontent, and excessive priestly influence characterised this reign, which was abruptly brought to a close by the revolution of 1830, and the election to the throne of Louis-Philippe, Duke of Orleans, as king by the will of the people. Progress in material prosperity made his government popular with the *bourgeoisie*, and for a time he held his ground. The capture of Algiers (1830) and war with Abd-el-Kader laid the foundation of France's great North African empire.

The Second Republic.—But the determined resistance of the king to the growing desire for electoral reform led at last to open insurrection in Paris; and, Louis-Philippe having abdicated (February 24, 1848), a republic was proclaimed under a provisional government. An insurrection of the Red Republicans in Paris (June 1848) was only put down after great slaughter. Louis Napoleon was elected President of the Republic in December 1848; but by the famous *coup d'état* of December 2, 1851, he violently set aside the constitution and assumed dictatorial powers; and a year after (2d December 1852) he was raised by the almost unanimous voice of the nation to the dignity of emperor, as Napoleon III.

The Second Empire.—The constitution of this second empire was the same as that of the first. A senate and a legislative body, shorn of all effectual parliamentary rights, screened badly the emperor's complete absolutism, under which, however, France made great advances in the development of her natural resources and in manufactures. Assuming the character of an adjuster of the wrongs of nations, Napoleon proclaimed himself a mediator in the Danish and Austro-Prussian wars, and the defender of the Italians against Austria, of the pope against the people of Italy, and of the Mexicans against the government of the United States of America. By his help the Italians were relieved from the Austrian yoke, and the pope was left master of Rome; Savoy and Nice were gained for France (1860); but in Mexico the emperor's intervention only led to greater bloodshed, and ended fatally for his protégé, the Austrian Prince Maximilian. He co-operated with Britain in the Crimean war (1854-56), and signed with that country a treaty of commerce (1860) on free-trade lines. Colonial expansion in Asia was begun by the acquisition of Cochin-China and Cambodia. Although the brilliant success of the Paris Exhibition of 1867 seemed to mark the consideration in which the emperor was held, his political credit had already then lost its

importance. At home the great financial embarrassments of his government were arousing the discontent of the people; and to avert the growing disaffection Napoleon offered (1869) to adopt a constitutional form of government, and to make some concessions in regard to freedom of the press. It was soon found that the responsibility of the ministry was fictitious, and that the emperor availed himself of its protection to cloak his own acts of personal government. The result of the appeal made to the nation in 1870, on the plea of securing their sanction for his policy, was not what he had anticipated; and the 50,000 dissident votes given by the troops in this plebiscite revealed a hitherto unsuspected source of danger. Confident in the efficiency of the army, and anxious to rekindle its ardour, he availed himself of a pretext to declare war against Prussia.

The course of events in the short but terrible Franco-German conflict of 1870-71 astonished Europe by its unexpected character, revealing at once the solidity of Prussian strength and the hollowness of imperial power in France. War was declared on the 15th July, and it had been the intention of the French emperor to cross the Rhine at Maxau and push his armies between the North and South German States so as to force the latter into neutrality. Such action required superiority in numbers and mobility at the very outset, besides good generalship. These advantages were soon found to be all on the side of the Germans, whose perfect organisation enabled every detail of mobilisation to be completed by the 30th July. Their troops, 518,800 men, with 1584 guns, were then formed into three armies—the first under General Steinmetz, the second under Prince Frederick Charles, and the third under the Crown Prince.

The French had with difficulty collected 270,000 men with 925 guns by the beginning of August, and these were deficient in transport and equipment. The emperor assumed the chief command, and had 128,000 men between Metz and the frontier at Saarbrück, some 47,000 under Marshal MacMahon on the eastern slopes of the Vosges Mountains, and 35,000 in reserve at Châlons. The first engagement took place on 2d August, when General Frossard's corps drove out the weak German detachment in Saarbrück, but did not push its success, and the Germans took the offensive next day. On the 4th the third army (130,000) on the German left met General Douay's advanced brigade (5000 men) near Wissembourg (Ger. Weissenburg), defeated him, and pressed on to Wörth, where MacMahon had taken up a strong position with his main body (45,000). The battle fought here on the 6th was disastrous to the French, who fled in confusion through the Vosges Mountains. On the same day the battle of Spicheren was fought between 67,000 of the first German army and 32,000 of Frossard's corps, and ended in the orderly retreat of the latter. As a result of these disasters the emperor found it necessary to retire towards Metz, and, after the fierce and undecided rearguard action at Borny on the 14th, entered that fortress on the following day with 176,000 men and 540 guns. He then abandoned the chief command to Marshal Bazaine. Meanwhile the second German army had reached the Moselle, and was threatening with its advanced troops the roads to Paris. This was unknown to Marshal Bazaine, although he had a large force of cavalry which should have kept him informed of the enemy's movements. He ordered the retreat westward to continue, and his staff made the great error of directing the bulk of the troops to use only one, and that the southernmost, of the two broad *chaussées* available. At least seventy-two hours would have been necessary to complete the with-

drawal from Metz under these circumstances, and the Germans had already placed some cavalry across the road near Mars-la-Tour. On the 16th they were vigorously supported (as was invariably the case in this campaign) by other troops, and succeeded in stopping the westward movement of the French. Next day the latter concentrated on the Gravelotte position, eleven miles in extent. On the 18th the pitched battle of Gravelotte was fought, and resulted in the French being driven back on Metz. Here they were surrounded, and, after several gallant but unsuccessful attempts to break out, surrendered on 27th October.

Thus within a month the regular armies of France had been rendered powerless to oppose the German advance. But in the meantime the *Gardes Mobiles* had been called out, and, with the remains of MacMahon's army, formed at Châlons a body of 120,000 men, with 324 guns, much disorganised, and almost entirely without discipline. With these it was determined to attempt to join hands with Bazaine by a northerly march, which was commenced on 21st August, without intelligence reaching the Germans, part of whose second army was again in motion towards Paris. On the 25th the Germans learned, it is said through a telegram in a foreign newspaper, of MacMahon's movements, and at once changed the direction of their march so as to intercept him. The effects of want of discipline and contradictory orders had greatly delayed his march, and he was much harassed by the enemy, till finally on the 30th the 5th corps under De Failly, having encamped near Beaumont without taking the precaution of protecting themselves by a chain of outposts, though it had been engaged the previous day, was surprised and driven northwards on Sedan. Here MacMahon collected his dispirited troops, but only to find that the enemy had surrounded him, and by vigorous forward movements had captured the bridges over the Meuse and the commanding positions round the town. A fierce battle commenced early on the 1st September by the attack on Bazeilles. This village was captured by the Bavarians and recaptured by the French, and ultimately burned. By noon MacMahon had been wounded, and General Wimpffen as senior officer had taken command, only to find further resistance hopeless, in spite of the gallant charges of the French cavalry under General Marguerite, who fell at their head. Nearly 500 guns were playing upon the French, who were crowded into Sedan and under its walls, and at 5 P.M. the white flag was hoisted on the citadel. Next day the emperor, who was with the army, surrendered with 83,000 men.

On the 4th Paris was in rebellion, the senate dissolved, the empress-regent a fugitive on her way to England, and France proclaimed a republic amid tumultuous excitement. Before the close of September, Strasburg, one of the last hopes of France, had capitulated, and Paris was completely invested by German troops; and on the 5th October the Prussian king had taken up his headquarters at Versailles. Gigantic efforts were made to raise armies in the provinces for the relief of Paris. Gambetta, escaping from the city in a balloon, joined the government at Tours, and by his energy got together many thousand armed men. These under the successive command of Generals D'Aurelles de Paladine, Chanzy, and Bourbaki fought stubbornly on the Loire, and with some slight success, threatening at one time to cut the German line of communications, at another to raise the siege of Belfort. But the surrender of Metz by Bazaine, and consequent reinforcement of the German armies round Paris, frustrated the first, and the masterly tactics of General von Werder on the Lorraine not only prevented the second, but

drove the French troops into Switzerland, where they were disarmed and interned. Whilst these events were occurring in the south and south-east, the Germans were overrunning the north as far as Dieppe, and fought a drawn battle with the French levies under General Faidherbe, who perhaps displayed more talent than any other French leader during the campaign. From Paris, where almost every able-bodied man was enrolled in the ranks, frequent sorties were made, and bloody battles fought in the villages to the east and south, Le Bourget, Champigny, Le Hay, Bougival, Raincy, &c., several of which were taken and retaken more than once. The city also underwent a bombardment for several days, from which, however, it suffered little, and it was not till hunger left no option, in January 1871, after a four months' investment, that negotiations were opened with the enemy at Versailles. The united efforts of the different branches of 'the Provisional Government of Defence,' respectively installed at Paris and Tours, then succeeded in bringing about an armistice, and a portion of the investing army entered the city, which had been till then cut off from all communication with the outer world, except by balloons and carrier-pigeons, and finally threatened by famine. They remained but a few hours, and with the concurrence of Germany the French nation now proceeded by a general election of representatives to provide for the exigencies of the country.

The Third Republic.—The First National Assembly of the French Republic met at Bordeaux in February. After receiving from the Provisional Government of Defence the resignation of the powers confided to them in September 1870, the Assembly undertook to organise the government, and nominated M. Thiers chief of the executive power of the state, with the title of President of the French Republic, but with the condition of responsibility to the National Assembly. On the 1st of March the preliminaries of peace were finally ratified at Bordeaux, the chief conditions being that the province of Alsace (except Belfort) and part of Lorraine, including Metz, should be ceded to the German empire, and that France should pay a war indemnity of 5000 millions of francs, and continue to be occupied by German troops till the money was all paid. This enormous obligation was discharged in September 1873, and during the same month France, after an occupation of three years, was finally relieved from the presence of foreign troops. In the spring of 1871 the peace of France was seriously threatened by a successful outbreak at Paris on the part of the Communists; but, after great bloodshed and grievous damage to public and private property, they were quelled by the regular army, and on 20th May order was restored in Paris.

The ex-Emperor Napoleon died in exile at Chislehurst in 1873. His son was killed in the Zulu war (1879). In 1873 M. Thiers resigned the office of President of the French Republic, and was succeeded by Marshal MacMahon, who appointed ministers willing to pave the way for the reinstatement of the Bourbon dynasty. But the plan of a fusion between the two branches of the family failed through the action of the Comte de Chambord, whom it was intended to make king under the title of Henri V.; whereupon the monarchical majority in the National Assembly, in spite of the growth of republican feeling in the country, confirmed for seven years MacMahon's tenure of the presidency. Matters thus remained in suspense between a return to the monarchical principle and a thorough acceptance of the republic till 1875, when, by the accession of some Orleanists to the moderate republican parliamentary party,

it became possible to pass constitutional laws for the republic. A senate and chamber of deputies represented the people; a president elected for seven years stood at the head of the government. The general election held in virtue of the constitution showed that France, under universal manhood suffrage, was now in favour of a parliamentary republic. A last attempt made in 1877 by the 'reactionary' parties to stem the tide of popular feeling met with a decided rebuff at the pollings. In presence of a republican majority both in the House of Deputies and in the senate Marshal MacMahon resigned his office (1879), and an out-and-out republican, M. Grévy, was appointed in his stead. Gambetta, the eloquent orator and leader of the republicans, became after the death of Thiers the paramount political power in France. After Thiers's death first Gambetta, then Jules Ferry, led the republicans. Public liberties (freedom of the press, of meetings, of professional syndicates) and municipal rights were secured; primary education was reorganised, being made free and compulsory and secularised. Protectorates were established in Tunisia, Annam and Tongking, and Madagascar, but costly colonial expeditions and the loss of French influence in Egypt led to Ferry's fall in 1885. Under Sadi Carnot's presidency (1887-94) parliamentary institutions were endangered by General Boulanger and Boulangism; Free Trade was abandoned in favour of Protection (1892); the Panamá scandal, economic crises, and anarchist outrages fomented unrest; and the Franco-Russian alliance was announced (1891). Carnot's popularity and tragic end rallied republican sympathies; monarchist power dwindled, and socialist representation in the Chamber grew apace. Casimir Périer resigned the presidential chair after but six months' tenure, and Félix Faure succeeded him (1895-99). His term of office witnessed the beginning of the Dreyfus case, the threat of an Anglo-French rupture over the Fashoda incident (1898), and the installation of Delcassé, Foreign Secretary from 1898 to 1905.

The presidency of Loubet (1899-1906) was notable for a Nationalist outburst under Déroulède; the *Entente Cordiale* (1904) with Britain—following on an arbitration treaty, the recognition of British predominance in Egypt and French interests in Morocco, and the settlement of the Newfoundland fishery dispute; friction with Germany over Morocco, temporarily allayed by the Algeiras Conference (1906) and the dropping of Delcassé; the reduction of military service from three years to two (1905); and a series of anti-clerical measures by strong Radical-Socialist ministries (Waldeck-Rousseau, Combes, Rouvier), including the suppression of unauthorised religious orders and schools (1901), the annulling of the Concordat, and the separation of church and state (1905).

While Fallières was president (1906-13), syndicalism, strikes, and labour troubles were much in evidence, and socialists were conspicuous in parliament and in ministries of the day. The Triple Entente (Britain, France, Russia) was consolidated (1907) to counterbalance the Triple Alliance (Germany, Austria, Italy). The Casablanca affair again provoked Franco-German tension during Clemenceau's premiership (1906-9), and the Agadir incident in 1911 almost led to war, Caillaux being obliged to cede part of French Congo to Germany in return for concessions in Morocco, which Lyantey now proceeded to organise as a protectorate. Poincaré was elected president in 1913, and Barthou, alarmed by German army increases, restored the three years' military service. Viviani carried another highly controversial measure, the income-tax law, in July 1914; and on the eve of the Great War (q.v.) Poincaré hurried back from a Russian visit, and Jaurès, the Socialist leader, was

assassinated. The Great War welded all parties in an *Union Sacrée* to defend their invaded country. Briand, Ribot, and Painlevé in turn formed cabinets; then the veteran Clemenceau saw the War to a successful finish, and represented France in the Versailles treaty discussions. An eight hours' day act and electoral reform were adopted in 1919, and at the November elections the Radical-Socialist majority in the Chamber melted away, power passed from 'Left' to 'Centre,' and the 'Right' was greatly reinforced. The health of Deschanel (president from February to September 1920) breaking down, Millerand, premier at the time, was elected in his place. The restoration of the devastated areas, reincorporation of Alsace-Lorraine, and organisation of ex-German colonies in Africa, support of Poland, crises with Germany, Greece, Turkey, &c., financial needs, Reparations, and a host of baffling post-war problems, continued to tax the energies and ingenuity of successive governments; and when Poincaré, who held office in 1922-24, occupied the Ruhr, the *Entente Cordiale* was severely strained by France's nationalist policy. In 1920 the *cinquantiennaire* of the Third Republic was celebrated with great fervour, the firm establishment of the constitution contrasting profoundly with the instability (thanks to manifold group coalitions) of French ministries, whereof over sixty held office in the first fifty years of the republic.

LANGUAGE AND LITERATURE.—The French language belongs to a family which offers unusual interest and exceptional facilities for philological and literary study. It is the best specimen of its kind, because the decomposed soil from which it springs—Latin—is school property; because the successive states it has gone through are visibly marked on its material and in its significance; because its line of development lies across the richest and most accessible historical ground. Long before the Romans conquered Gaul their speech was already undergoing certain specific changes, whence in due course and in the proper places the modern languages of Italy, Rumania, Spain, Portugal, and France would take their rise. These changes consisted principally in the weakening or dropping off of primitive elaborate case inflexions, the suppression of short vowels between consonants that could with ease be pronounced together, a gradual increase in the stress laid in pronunciation upon the accented syllable, the use among the Roman plebs of forms and words not accepted in the polished classes of society, and the tendency to depart from the earlier and synthetic modes of expression in order to introduce into the mechanism of speech a new class of words, which slowly took the place of perishing case and verb inflexions.

Through Latin, its ancestor, French belongs to the

Aryan stock of languages. Along with its sister-languages, Roumanian, Italian, Spanish, and Portuguese, it sprang into being when soldiers, colonists, and merchants, in the course of several centuries of Roman domination, had saturated western and southern Europe with their *lingua romana rustica*, or common Latin speech, an essentially popular and unliterary form of utterance, but forcible and instinct with an irrepressible vitality. This Latin of the Roman people and of their European possessions is known to philologists in the shape it received after the invasion of the barbarians and through the admixture of Teutonic elements, under the name of Romance. It is as it were a vegetable mould, spread to a great depth over the surface of western and southern Europe; and from its common properties were formed, by a process of differentiation, the special and localised soils suited to bring forth ultimately the distinct literatures of Italy, France, Spain, and Portugal. In France Romance gave birth to Old French, which can be divided into three successive periods—the period of formation, the flourishing period, and the period of decay. The first is contemporaneous with the earliest middle ages, and its origin, like that of French history, dates back to the conquest of Gaul by Rome. The Celtic dialects were overpowered by the *lingua romana rustica*. While the masses spoke popular Latin, the literary dialect of Cicero was written and spoken by the educated and governing class: it was a class language, and continued so till the church was left alone in possession of this effete legacy of ancient Rome.

The *lingua romana*, according to a law inherent in every language, was already assuming local peculiarities in different parts of Gaul when the first move towards the formation of a French language, the campaigns of Julius Cæsar, was completed by a second, the settlement in Gaul of the Frankish, Burgundian, Saxon, and Gothic tribes from beyond the Rhine. The formation of different dialects received fresh impetus from the complete disruption of the Roman power in the West. From that day, the processes of decay, which till then might be considered as modifications within the *lingua romana*, assumed a regenerative character and became the starting-point of a new language. To the Franks has fallen the honour of having their name attached to it. This Germanic title has by no means affected the inner construction of the language. Teutonic influences can be traced in goodly number in the vocabulary and phonetics of Old French; but the grammatical framework and the syntax, which developed only in the late stages of Old French, are wholly and absolutely Latin in origin and Latin in spirit. Language in Gaul, as elsewhere, ran into types: dialects, whose primary causes are obscure, were formed. In the valleys of the Rhone and of the Garonne, in the whole country (very nearly the half of modern France) verging to the Bay of Biscay, from the mountains of Auvergne southwards, early French was not French; it inclined to the Italian and Spanish modifications of Romance on which it bordered. These southern dialects, known under the collective name of *langue d'oc*, fell out of the race for supremacy when the centre of political and military power in Paris became strong enough to absorb the Mediterranean border in its circle of influence. By degrees inner troubles and invasion from without deprived the southern speech of its national significance as a body of language. Nowadays Provençal (q.v.) is for the people a patois, for literary antiquaries and philologists a curious study. Its victor, the *langue d'oïl*, the parent of modern French, has had a triumphant career. Geographically, to it belonged the valleys

of the Saône, Loire, Seine, Scheldt, and Meuse. Scholars distinguish four dialects in it. The dialect of Paris became paramount after the building up in Paris under the Capetian kings of a natural centre for the gradual nationalisation of France. The culminating point of Old French was reached when it had evolved fully its 'half synthetic system' in the 12th century.

The language thus shaped brought forth a stupendous amount of literature. For two centuries medieval French was the polite language of Europe, more so than modern French has ever been; for after the early but transient literary outburst of the *langue d'oc*, and before the dawn of the Italian Renaissance, French had no rivalry to fear from still shapeless contemporaries. It was currently held till well into last century that French literature had its roots in the Augustan age of Latin culture, and that the Hellenism of the Renaissance was the first air in which it flourished. The mythological apparel of French poetry and the classical rhetoric do admittedly proceed from that source. But hearts beat and imagination wove its webs of fancy in France ages before scholars imported the literary finery of Greece and of Rome. The natural trunk of French literature, if not of French letters, casts its roots in the same soil whence the language sprang. Language, nationality, and society are even in the middle ages the constituent elements of history, and the true nature of the times is better elicited from them than from the records of military violence.

In the flourishing period of Old French, society is feudal, its character is the division of men into four sharply defined classes: the nobility, whose occupations were mainly martial, and who in consequence fostered an epic literature; the burghers, among whom are first found the more strikingly national points—common sense, wit, good-humoured satire, gracefulness, a fresh and nimble style; the villeins, affording to the burgher plentiful material for jest; the clerics, including the clergy and all professional men, who spoke and wrote Latin, and who when they took to writing in French brought to it the older language's historical and philosophical qualities. Those four classes had their being between the four walls of medieval immutability—the Catholic religion, feudalism, monarchy, and the grossness of their world-conceptions. Thus rough-hewn, French society, from the 11th to well into the 14th century, assumed and preserved throughout the Crusades, throughout the struggle between emperor and pope, in spite of the annexation to England for a time of a large portion of France, the proud position of master and arbiter in matters of the intellect and of social commerce. The deeds of war of the Frankish kings of the Merovingian and Carolingian dynasties called forth French epic poetry. The appearance of Clovis as the champion of the Catholic faith against the Arian heresy, of Charles Martel as the protagonist of Christendom against the Moslem Arabs from Spain, of Charlemagne as conqueror of the heathen Saxons in Germany and of the Mohammedans on the banks of the Ebro, fed an ever-swelling strain of song till it rang its loudest in the *Chanson de Roland* (11th century). Round this epic poem, struck up by the Norman *trouvère* at the battle of Hastings, further royal, feudal, and biographical epics ranged themselves, almost all grounded on fact, some borrowed from antiquity, some suggested by the Crusades, some imported from Brittany. The last class may be claimed by Great Britain as derived from the literary fund of its oldest inhabitants; for, when the Celts of Britain had been driven from the east coast by the Angles and the Saxons, a part of them crossed the sea to French Brittany, taking with them the

legend of King Arthur. Those who remained in Wales, after charming their Teutonic conquerors by their gift of song and poetry, fascinated with still greater ease the Normans romanised by their long stay in France. The *Round Table*, *Perceval*, *Tristan*, *Lancelot* were incorporated in Anglo-Norman literature, till they won for French in their continental form the prize of narrative poetry. From France those romantic stories passed into the Netherlands, Germany, Italy, and the Spanish peninsula, carrying everywhere that air of chivalry and gallantry which in matters of the imagination gave an ideal to society and constituted its moral unity. In the middle of the 13th century the purely epic cycle and the romantic cycle engrafted upon it were complete. Then came in verse the opportunity of the story-teller and in prose that of the chronicler. The French fabliau or tale is unequalled for wit, humour, alertness, good-tempered malice, and refined mockery, with a strong dash of the salt of coarseness. The Voltairian spirit already tripped lightly about, and the fabliau writer, in his swift, pointed treatment of social matters, is the forerunner of the *esprit Gaulois* and Parisian vivacity which feed a distinct current in the stream of French literature. Boccaccio and Chaucer drew much material from the French elaboration of tales hailing from all quarters of the globe.

Whole collections of fables were fathered upon Æsop, dubbed to that purpose with the familiar name of Isopet. By degrees the short fable was succeeded by long semi-epic, semi-satirical compositions, in which a moral was aimed at man by the transference of social relations to the animal world. The *Roman de Renart*, the most representative and most comprehensive of these productions, was imitated and translated everywhere, and its more interesting parts have remained a common possession of all literature, suggesting for instance the Flemish *Reynaert de Vos*, and finally appearing as Goethe's *Reineke Fuchs* in modern literature. In the 14th century the latest French compilation of Mr Reynard's exploits throws a deal of light on the society of the time. It expresses the ideas of the comparatively wakeful and wealthy middle class then occupying the large towns, their hatred of the landed aristocracy, and indifference to the villain's lot. The French have to thank the Crusades for their first histories. Some of these belong to Anglo-Norman literature, and recount the deeds of France's ally, Richard Cœur-de-Lion. But they are outshone by Villehardouin's *Conquête de Constantinople*, the masterpiece of historical composition in the middle ages proper. He reminds us of Herodotus as the *Chanson de Roland* reminds us of Homer. The sixth crusade and the life of Louis IX. are the subject of Joinville's *Mémoires*, while various causes resulted in an outburst of French or rather Anglo-Norman historical productions in England which did not extend beyond the beginning of the 14th century. History in the middle ages being heroic, epic, and chivalrous rather than didactic and philosophical, the aristocrats provided the clerics with the material and spirit of its treatment. But as time wore on the latter in their turn enriched French literature with branches that are entirely their own. They began to write in the character of students and scholars, of moralists, caricaturists, educators, dramatists, and professors of religion. Their most important contribution to general literature is the *Roman de la Rose*, a vast allegorical treatment of the lover's woes and the lover's bliss in the pursuit of the object of his passion. Begun by Guillaume de Lorris, the poem was continued and diverted from its original purpose by Jean de Meun; it became popular throughout

Europe in the multitudinous artificially-cultured court circles of the 14th century. It passed into the Dutch, Italian, and English languages. It imparted its character to French literature till the end of the 15th century, was transcribed and printed during 300 years, and stands in an indirect relation to the 'romans' and 'précieux' works of the 17th century. Lyrical poetry has, properly speaking, no cradle of its own within the strict limits of French medieval literature, for it was brought thither from a sunnier, warmer, and softer southern air. Italian, Spanish, and the *langue d'oc* were the natural and early vehicles of lyricism in Europe. Of these three languages the last named was the first to bear fruit. There prevailed in Provence some particular rules of etiquette and of good breeding, upheld by a brilliant society in which women held the foremost place. The troubadours in their lyrics held up the mirror to that society and reflected its tastes. When the south had fallen a victim to the bane of persecution and military supremacy extended upon it from the sterner north, the art of the troubadours found in the 13th century a temporary abode in Champagne, Picardy, Flanders, and Artois, whence it passed to Germany, to Italy, to Sicily, to Spain, to Portugal, inspiring everywhere the first lispings attempts of nationalities whose languages have since proved themselves to be, as lyrical instruments, superior to the French.

The 15th century witnesses the linguistic transformation of Old French into Modern French. The last traces of case inflection disappear, the analytic form of language supersedes in all essential parts the half-synthetic system. The French mind acquires these qualities of reflection, French thought takes that philosophic turn which distinguishes the idealism of the intellect from the idealism of the imagination. Froissart, in his *Histoires*, wields an inquiring as well as a picturesque pen. His successor, Philippe de Comines, the historian of Louis XI., is still more of a moralist and of a politician. Charles d'Orléans, snatching from the perishing troubadours the thread of lyrical poetry, passed it to Villon, who wove into its silk many a coarse hempen filament, till Clément Marot raised French verse to religious solemnity in his translation of the Psalms, preserved its grace in his epistles, and gave it a pathetic ring in his elegies. In the meanwhile the Italian Renaissance was filling with its glory the world of art and of literature. Native and spontaneous literary activity was paling before the light of the revival of learning. With the accession of the House of Valois to the throne we find at once that the spirit of France has passed away from the old into a new society and a new literature. France will now receive the lessons of ancient Rome, ancient Greece, and modern Italy before it does again original work and resumes its supremacy in Europe. French society becomes polished, its local provincial centres die out, and culture flourishes in the court of the king. Francis I. is proclaimed the father of letters. The state is organised, there is a general intellectual impulse, women are promoted to the place of honour in social and court life. French officers, sent year after year at the head of French troops to Italy by Charles VIII. and Louis XII., brought back a knowledge and a love of art and letters. Italian architects built mansions for them and palaces for the royal family. Italian painters and sculptors hung pictures and set up statues in their halls. Italian scholars interpreted for them the masterpieces of Roman and Greek literature. No longer mere power or physical prowess, but mind was the object of a gentleman's ambition. It became the fashion at court to show enlightenment by attending the preachings of the Reformers. Francis I. laid the foundation of the Bibliothèque

Nationale and of the Collège de France. He, and his sons after him, encouraged artists and scholars. Paris numbered then 500,000 inhabitants, of whom 15,000 were students.

In the general excitement of the Renaissance and the Reformation, literature could not but move in the same direction as society at large. Italian comedy ousted the *mystères*, *sotties*, and *farces*; the imitation of Greek and Latin authors reduced the flow of inspiration in poetry, and burdened it with artificial rhetorical rules and with a mass of ill-advised borrowings from the Latin vocabulary and from the Latin syntax. Ronsard and his *Pléiade* stood in the van of this movement, which Régnier endeavoured to stem, while Rabelais, mixing the new material with the old in an ill-assorted, stupendous mass of cumbersome learning, low jesting, high thinking, and word-rioting, came near being the burlesque Shakespeare of his age, whose energies are best represented in we know not which of the numerous veins running through *Gargantua* and *Pantagruel*. No two minds could be more different than those of Rabelais and Montaigne, the great prose-writers of the 16th century, yet only the Renaissance could produce either; the first, with his reason driven wild in pursuit of the visions of his imagination; the second, a blithe Greek sage, carrying his wisdom lightly and discoursing as if arm in arm with Plutarch, his model. Rabelais, Montaigne, Calvin, and Descartes, by setting French prose on the basis afforded by the revival of learning, drew to themselves some of the attention then given to Italy. Poetry was rescued from Ronsard's exaggerations by Malherbe only to be tapered down almost out of existence by over-much attention to elegance, refinement, lightness, and style. Looking forward through the spans of time, we find that, divorced from nature and limited to the expression of the social emotions, poetry is poetical with Lafontaine only in his *Élégie aux Nymphes de Vaux*, with Racine only in the choruses of his tragedies. As for the professed lyric poets of the 17th and 18th centuries, their performance bears the impress of the sterility and rhetoric of their Latin models. J. B. Rousseau, Lefranc de Pompignan, Lebrun, and Pindare are worse sinners in this respect than Racan, Chaulieu, and Parny. Lyricism finds better interpreters in church orators, such as Bossuet (*Oraisons Funèbres*), Bourdaloue, Massillon, and Fléchier, all of the 17th century. It pervades the glowing pages which love of nature and effusion of sentiment dictated to J. J. Rousseau and Bernardin de St Pierre in the later part of the 18th; it dwells in the religious fervour of Chateaubriand and in the passionate enthusiasm of Madame de Stael on the threshold of the 19th. André Chénier was the first to restore some soul to poetry, in the pure Greek note which he sang during the horrors of the Revolution.

Such a long eclipse is partly explained by the premature application to literature of standards of taste and of formal criticism. Malherbe subjected his talent to a personal discipline which Boileau consolidated into a set of rules enforced with the lash of satire. Corneille wrote his tragedies early enough to remain comparatively free from this rod, but Racine acknowledged Boileau as his master. The 17th century is in France the age of authority in literature as in everything else. The French Academy, founded by Richelieu in 1635, to establish positive rules for the French language and to render French speech not only elegant, but also fit to present all arts and all sciences, gave an earnest of its future labours by an endeavour to curb Corneille's waywardness in composition. Public opinion at court and public opinion in town circles—for Paris was becoming a centre of culture and thought, forming together with the court the whole

of French society—fell by degrees into line with the Academy and with Boileau. Thus was formed, along with French unity, the unity of French literature, and to this period is ascribed the name *classical period*, to distinguish it from the period of liberty and individualism ushered in after the Revolution and the Empire, by the rise of liberalism in politics and the return to freedom in the matter of prose and verse composition. As long as town and court moved together in the same direction, the unity of French thought, of French literature, and of French political development remained unimpaired and produced its fruits good and bad. After Corneille's sublimity and his representation, not without some Spanish staginess, of the conflict of duty and passion in heroic human breasts, came Racine's polished and courtly expression of the agitations of the heart. Molière, the greatest French painter of men from life, showed himself in his *Tartufe* the scourge of hypocrisy; in his *Misanthrope* he was austere and touching; in the *Femmes Savantes* and in the *Précieuses Ridicules* he exposed the false and pedantic enunciation of the woman of the period; in the *Avare* he related the plight of an unconscious miser; playful withal, castigating with sobriety, ruthlessly just and gently forgiving, uproariously funny and immensely suggestive, acting his parts himself in the happiest fashion, using the sharpest, tersest, and brightest French. Regnard followed him, but far behind. Then came Destouches, Le Sage, Piron, Gresset, Sedaine, without Molière ever having a rival, except perhaps Lafontaine, whose fables, conceived in the same inimitable French vein, are one and all natural or comic little dramas in which an apparently artless exhibition of the ways of animals and things leads to a neat moral applicable to man. Florian followed in his footsteps at a respectful distance. Madame de Sévigné gained a place for letter-writing as a distinctly French art, an accomplishment in which many Frenchwomen have excelled after her. In contrast to Bossuet's Hebrew-like eloquence and militant ecclesiasticism stood Fénelon, gentle, suave, and versatile, ever healing wounds and pointing a warning finger to dangers ahead. Totally different from either of them had been Pascal, an introspective pessimist oddly placed in the vestibule of an impersonal age, wrestling with doubt, bending the language to his intellectual agony, and planting upon the Jesuits the stigma of his honest, piercing satire. La Rochefoucauld, who wrote his contribution to moral philosophy before La Bruyère, was also a memoir-writer, a gift in which Cardinal de Retz, the naturalised Scotsman Hamilton, and the Duc de St Simon all excelled.

Amidst the mistaken foreign and home policy which was striking at the very roots of the nation, French literature offered towards the end of the long reign of Louis XIV. a spectacle of imposing intellectual force. France established thereby so well its claim to the leadership of society and literature in Europe that, thanks to a lull in native literary production, as in England, or to a comparatively backward state of culture, as in Germany, or to a paralysis of the national vigour, as in Italy, the French 17th century might seem to protract itself in all these countries even at a time when a total change was passing over French society, and pointing its literature in a new direction. The age of Louis XIV. was, above all things, that of a well-balanced literature, the work of men whose nerves are not upset, who are fully satisfied with the work suggested by their situation. Their stock of ideas was adequate to their power of treatment, and nothing came to mar the dignity and gravity with which they approached their subjects. There is a wholesome moral tone underlying their performance, and the

kind of repose bred from the illusion that one's work is final. But Louis XIV.'s senility and fanaticism, and after him the license and unscrupulousness of the regent, disorganised the court; a larger number of thinking and able men collected in Paris than the service of the state and of the church could occupy. Parisian society, once educated by the court and long led by it, broke away, and violently rebelled against an irksome tutelage. It returned to freedom first, then it welcomed adventurous minds which abandoned troublesome spiritual and moral loyalties to swell the ranks of drawing-room malcontents, while below them seethed a large class of *intrigants* and schemers recruited in the overgrown establishments of noblemen and courtiers. Literature, from being an art in itself, became subordinate to ideas; by an enormous influx of ripening thought it became a vehicle for hitherto unexpressed political, moral, religious and scientific matter. Till 1750 the disintegration of the old social body remained latent. Still, Montesquieu's *Lettres Persanes* and his *Considérations sur la Grandeur et la Décadence des Romains* announced plainly enough the advent of social satire, and the application of philosophic method to the study of political history. But his *Esprit des Loix*, by showing the interdependence of physical and moral laws and the conditions to which is subjected the legislator's apparent liberty, marks a clear departure from the traditional theories of government.

The great mouthpiece of the spirit of the age, Voltaire, belongs still in pure literature to the times of Louis XIV. His tragedies are classical, his literary criticism is that of Boileau, his poetry is an academic display of wit and sociability; but the remainder of his works form a complete battery in which his tales represent the light artillery and his histories the heavy guns. Combining passion with philosophic acumen, strangely divided between vanity and generosity, the personal friend of kings and the advocate of individual and popular rights, preaching tolerance and openly undermining public respect, deep in prejudice and the enemy of superstition, he showered upon the tottering edifice of French society pamphlets, treatises, letters, discourses, epistles—all of them shafts pointed with sarcasm, finely weighted with a touch of plausible learning, and feathered from the wing of his sparkling imagination. He was assisted in his incessant warfare by a host of talented and original thinkers. Sensualistic followers of Locke, like Condillac and Condorcet; combative materialists, like Helvetius and D'Holbach; encyclopædists, headed by Diderot and D'Alembert; earnest moralists like Vauvenargues; writers of novels and plays with a purpose, such as Le Sage and Beaumarchais, or with the object of minute psychological analysis, such as Marivaux and l'Abbé Prévost; naturalists, like Buffon and Bernardin de St Pierre, showed each in his own department of letters, art, or science, many even in several departments at once, one common spirit and an identical zeal by which all thinkers and writers, often unknown to themselves, worked in concert as if holding of malice prepense an intellectual Pentecost. The age was too much in earnest for plain comedy; it was too bitter for poetry; Gilbert almost alone wrung a true cry from his heart; Crébillon writes some overwrought tragedies, and Laharpe stands forth as the last critic of the Boileau school.

At this juncture J. J. Rousseau appeared to complete Voltaire. Born in Geneva, where the political institutions towards which France was moving were partly in existence, early weaned from an atmosphere still nominally Calvinistic, professedly at war with the philosophers, he gave them the support of his persuasive eloquence,

passion, imagination, inspiration, enthusiasm, heating in fact their cold intellectualism with an emotional fire that quickened the seed of mischief, and raised the nation's pulse to fever-heat, till even Rousseau's voice was lost in the clamour of the Revolution. He broke fresh ground in the science of politics by his *Contrat Social*, in the art of education by his *Émile*, in pure literature by his *Nouvelle Héloïse*, painting a picture of more natural morals, often greatly at variance with morality. An unworthy son of the society of his day, he passed condemnation upon it. In the year after his death the political assemblies began the realisation of his ideas. Thus literature, at work among other causes, led straight to the Revolution. The ring of Mirabeau's oratory was heard for a few years above the turmoil in which perished the poet André Chénier.

As long as the axe did execution in France, and as long as Napoleon's sword held sway in Europe, literature did not raise its voice. Madame de Staël drew her inspiration from without, though mentally and emotionally in touch with J. J. Rousseau. She called the attention of France to the benefit it could derive from the study of independent foreign literature, such as the nascent literature of Germany and the established literature of England. She showed that the poetry of the Renaissance, derived from the ancients, elaborated into formal classicism, burdened with pagan associations, and modernised in Italy and Spain, could not be compared with the hidden bubbling springs welling forth in the chivalry and cathedrals of the land, and flowing from the lips of the greatest poets out of France.

By doing away with every sort of restriction and privilege the Revolution imparted a new unity to the French nation, immensely developed the function of the middle class, and threw open vast prospects to its hopes and ambitions. Becoming the centre of gravity of the nation, and holding in its hands the reality of power, it re-echoed the ideas of Madame de Staël. Chateaubriand, finding in a return to medieval ideals the proper food for his imagination and the right colours for his style, unwittingly favoured her liberalism. Then Lamartine stepped forth as the lyrical poet long looked for in vain, revealing in his reposeful, tuneful lines, often sad, and ever bathed in a dim religious earnestness, a beautiful and sympathetic side of French poetic sentiment which had never yet found a mouth able to utter it. A whole school of lyric poets followed in Lamartine's footsteps—Alfred de Vigny and Victor de Laprade being among the greatest. Casimir Delavigne is not free from the besetting sin of rhetoric, and Victor Hugo was master of too many instruments besides the lyre to be classed here. His position is that of founder and head of the French romantic school, as the men called themselves who threw off all allegiance to the classical traditions. He philosophised for his followers on romantic aesthetics, explaining what relation ugliness bears in art to beauty. He applied his doctrine in a series of dramas, to one of which, *Hernani*, the romanticists nailed their colours and compelled the public to bow. From 1830 to 1885 Victor Hugo was in all kinds of literature, at first an initiator, then a revered and victorious chief, and during his old age an idolised master. Under his leadership formalism was excluded from the technique of poetry; ingenuity and a free adaptation of rhetorical means to poetical ends taking the place of compulsory standards. In prose style was left similarly to individual initiative; the language being boldly bent to the purpose of the writer, and receiving its moulding from the originality and character of his mind. There was no longer a question of imitating set

models and complying with fixed precepts. Expression received its form from within. Hence a new, multiple, and often eccentric art, seeking too much after the pictorial and sensational significance of words, a general strain on the resources of language and of literary expression, but a profusion of striking effects, and the transference to the pen of many capabilities belonging properly to the brush, the pencil, or the chisel. Victor Hugo inaugurated thus a new method in literary composition. Taste and wit became of less moment, because literature no longer rested upon society as a whole, but upon the nature of each individual writer.

Romanticism represented three things: a return to ideals medieval, a recoil from ideals classical, and the awakening of modern France to its own ideals. Victor Hugo embodied all this in his long career. Royalist and Catholic at first, he sang odes to the past; adversary of the Academy and of the Théâtre Français, he gained seats in the first for his followers and the boards of the second for his and their dramas. Then, interpreting the inner life of the bourgeoisie, he wrote for them the poetry of their daily musings, of their affections, of their children. Next, led on to liberalism and to the breadth of human charity, he with one hand branded Napoleon III., with the other revealed what gleams of spiritual beauty shine unknown in the hearts of the lowest and poorest, while his imagination wrought into epic poems the history of the world and the destiny of man. Nobody ever did so much with words, and words never did so much for any one. The aesthetics of romanticism bore fruit in the transformation of dogmatic criticism into literary history. Sainte-Beuve applied the theory of the new practice with so much success that the critique of art and literature, always a favourite pursuit with the French, but long a cause of weakness, became one of their strongest points, and most beneficial to all literature. With him, Villemain, and Scherer, literary history became comparative as well as personal. To attempt an enumeration of Victor Hugo's followers, or of the writers in any given field, would break the proportions of this general survey, besides conveying a wrong impression, for it is a feature of this century that the activity of talent pervades several fields, and expresses itself in verse and in prose almost indifferently. Lamartine, for instance, was an orator and a historian as well as a poet. Victor Hugo was still more discursive. Few men sat down to their work with the intention of deriving their inspiration from the nature of their subject only. Subjects were rather chosen as themes, and their treatment showed a complicated compromise between man and thing. Michelet's history, for instance, is not separable from Michelet. After the first ado of the romantic movement, which immensely broadened the stream of French literature, the old and new flood mixed their waters and ran as it were into four principal masses. Poetry became more and more of an art and less and less of a substance, except in Alfred de Musset, who rivalled the finest performance of Lamartine and Victor Hugo without sacrificing his originality to either, sometimes toying with life, sometimes sneering at it, sometimes uttering the cry of man unredeemed from vice, crushed in sorrow, and bound in weakness, in a voice so true, in so sweet a melody, that he is the most loved of French poets. Below him stand the Parnassian poets, Leconte de Lisle, Baudelaire, Sully-Prudhomme, François Coppée, Catulle Méndès, and José Maria de Heredia; and conspicuous among his minor contemporaries are the ultra-romanticists Gérard de Nerval and Théophile Gautier.

The drama, to which Casimir Delavigne, Alfred

de Vigny, and Alexandre Dumas laid stepping-stones for Victor Hugo, fell after him into the hands of the semi-classicist Ponsard, of Augier, Feuillet, Alexandre Dumas fils, and Sardou. The comic stage, occupied by the rapidly-constructed and rapidly-vanishing productions of Scribe, only seldom saw a real comedy. But as a set-off some of the old comic force entered now and then into the romantic drama, and trickled into many novels and romances. These were a genuine growth of the times, and, for variety, artistic treatment, psychological analysis, they rank high above every novel published before, with the exception of but a few to which they are historically affiliated. Novels are fantastic with Ch. Nodier, historical with Alfred de Vigny, realistic with Mérimée, Balzac, Flaubert, and Daudet, panoramic with Alexandre Dumas the elder, homely with Sandeau. George Sand, possessed like Madame de Staël of almost masculine gifts, and, like her, one of Rousseau's disordered kindred, exhibited in herself and in her books the play of the passions in their natural state, till she poured forth her mellowed ardour in pure idyls of country life. There is but a distant affinity between the 'realism' of some of the preceding writers, the 'naturalism' of Zola and Maupassant, and the 'impressionism' of the De Goncourts. A wave of liberalism in the Roman Catholic Church bore Lamennais, Lacordaire, and Montalembert to oratorical fame, while Renan shone in church history, Cousin and Auguste Comte in philosophy, Taine in scientific psychology. Béranger stood almost alone in having but one specialty. A liberal, though under the spell of the Napoleonic military glory, he raised to an art his turn for penning popular songs. The analytical qualities of the French mind and its power of constructive writing were nowhere better displayed than in the department of history. A. Thierry with fidelity and picturesqueness, Guizot with some heaviness, Thiers with patriotic complacency, Quinet and L. Blanc with too much passion, Michelet with an excess of the poetical faculty, De Tocqueville with breadth and insight, attached their names to some masterly work.

The end of the 19th and beginning of the 20th century found French literature in vigorous if somewhat distracted condition. Old schools still lingered, but reaction was strongly marked in every field. Groups or *chapelles* formed—and reformed—by the score. In poetry the Symbolist school, *ci-devant* 'Decadents'—Verlaine and Mallarmé at their head—rebelled against the lapidary Parnassian style, and began the cult of vagueness and obscurity, *vers libre* and word-music, which was taken up among others by Vielé-Griffin, Henri de Régnier, and the Belgians Verhaeren and Maeterlinck. The romantic tradition was upheld by Richepin and the Comtesse de Noailles; the classical by Jean Moréas and Charles Maurras. But the most remarkable development was the neo-Catholic nationalist school, represented in verse by Guérin, Claudel, Francis Jammes, and Péguy, the poet critic who fell in the Great War, which gave fresh impulse to this *traditionniste* movement. In drama the same *macédoine*: naturalist plays from Henri Becque, symbolist from Maeterlinck, romantic (verse) from Rostand; above all *pièces à thèse*, psychological, physiological, sociological—sensuous with G. de Porto-Riche, censorious with Briens, pungently witty with Donnay, tense with Hervieu, violent with Bernstein, elevated with F. de Curel, to name no more of a brilliant band. Antoine's Théâtre Libre fostered individuality and audacity. In the novel these found still freer scope. Anatole France, foremost French man-of-letters of his age, linguist, historian, archaeologist, artist, philosopher, and what not, has a

place apart. That master-analyst, Paul Bourget, helped to give naturalism its quietus, and following the psychological novel of Stendhal, showed new possibilities in realism. The *roman social* quickly took root. While Pierre Loti and the Tharaud brothers go abroad for their vivid pages, Bazin, Bordeaux, Boylesve depict French provincial life. While André Gide and Marcel Proust plunge ever farther into the dark unfathomed depths of the human soul, Pierre Benoit disports in romantic adventure. While Romain Rolland prides himself on his serene internationalism, Maurice Barres, apostle of nationalism, waxes lyrical over his native soil. With Jules Lemaitre, Brunetière, Faguet, Lanson, Doumic, Sarcey, there was no lack of critics to direct, dote, damn, and disagree. Bergson and Boutroux showed that philosophy was still a form of literature distinct from fiction. Henri Fabre, the naturalist, won the title of the Insects' Homer. Lavissee, Sorel, Hanotaux, the historians, Berthelot the chemist, and other savants took their seats among the 'Immortals.' Vigour and variety marked every department of letters at the dawning of the new century, and the War which ravaged and welded France brought no unity and no devastation to its rich perennial literature.

In France more than in any other country mental power is accompanied by the literary faculty. Hence all science and all manner of erudition claim a place in literature. An inquirer going the round of the interests of civilised man would with difficulty find an object of study or a branch of culture in which the French could not offer a model of presentment. Their literature is marked by symmetry and fullness in its successive periods, by continuity in its unity and variety, by evenness in its distribution over the pursuits of man, by regularity in its function towards society, by the amenableness of the people to its influence. Literature is a mightier instrument with them than elsewhere. They quickly respond to it. The susceptibility of the national character, its somewhat feminine eagerness and quickness of perception, which keeps society as it were in a continual whirl of integration and disintegration, and ideas in perpetual revolution, are the very endowments which make their literature the most uniformly readable of all. With a little less of the mind-quality about them, they would be happier and wiser, perhaps, but Europe would be duller and poorer.

The history of the French language may be studied in the dictionaries of Diez, Brachet, Littré, and Clédat, and in Brunot's *Histoire* (1905 et seq.); its grammar in such books as those by Diez, Bartsch, Brachet, and Gaston Paris. The serial *Romania* (since 1872), the *Zeitschrift für Romanische Philologie* (since 1877), the *Romanische Forschungen* (from 1883), Dr Wendelin Förster's *Altfranzösische Bibliothek*, and Suchier's *Bibliotheca Normannica* may also be consulted.

For the history of the literature, see the monumental *Histoire littéraire de la France*, begun by the Benedictines and continued by members of the Institute (i.-xxxv. 1733-1915), but reaching only to the 14th century; Petit de Julleville's ample *Histoire de la Langue et de la Littérature française* (1897-99); and for early texts the works of J. J. Ampère, Léon Gautier, Aubertin, Gaston Paris, P. Meyer, and J. Bédier. For the 16th century Darmesteter and Hatzfeld; for the 17th, Voltaire, Demogot, Laharpe, Sainte-Beuve, V. Cousin, Fournel, and Dupuy; for the 18th, Barante, Villemain, Bersot, Albert, Lord Morley, E. and J. de Goncourt; for the Revolution, J. Chénier, Gérusez, Maron, G. Merlet, and the De Goncourts. For the 19th century and contemporary literature, books by Charpentier, Merlet, Le Goffic, Mme. Duclaux, and critical essays on individual writers by Vinet, Sainte-Beuve, Villemain, Montégut, Prévost-Paradol, A. Pontmartin, Caro, Taine, Scherer, Paul de St Victor, G. Planche, H. Etienne, St René Taillandier, Janin, Saint-Marc-Girardin,

Lemaitre, Bourget, Brunetière, Faguet, Pollock, Saintsbury, and Henry James.

There are manuals covering the whole ground by Lanson, Brunetière, and Faguet, and in English by Saintsbury, C. H. C. Wright, Dowden, and K. T. Butler (1923). See also the *Grands Écrivains* series; editions by the societies of *Anciens Textes* and *Textes Modernes*; and the articles on the chief French writers in this Encyclopædia, as well as CHANSONS DE GESTE, DRAMA, FABLEAUX, NOVELS, PROVENÇAL, ROMANCE LANGUAGES, ROMANCES, ARCHITECTURE, MUSIC, PAINTING, SCULPTURE.

France, ANATOLE (pseudonym of Jacques Anatole Thibault), French man of letters, and the foremost writer of his time in France, was born in Paris, 16th April 1844. From his father, a bookseller and bibliographer of the Quai Malaquais, he inherited gifts of scholarship, while from his mother, a woman of religion and a lover of beauty, there came to him faculties of fancy and imagination. Outwardly the circumstances of his life were uneventful. Educated for a short time at a school in the Faubourg St Germain, and later at the Jesuit Collège Stanislas the chief influences which went to the moulding of his mind were the classics of Greece and Rome, and the spirit of the 18th century in France, while scarcely less important was the environment of his earliest years—old Paris, with its historical associations, with its book-stalls and curiosity-shops, with the micro-cosmic life of its quays. On the completion of his education there followed a period of teaching and also of desultory journalism, when work in verse but also in prose was contributed, mostly to the pages of ephemeral reviews devoted to furthering the aims of the Parnassian poets. To these activities the appearance in 1868 of *Alfred de Vigny*, a study of the great precursor of the Parnassians, was a natural sequel, and this was followed in 1873 by the publication of *Les Poèmes dorés*, a first volume of verse in the Parnassian style. In 1874 France was on the staff of the Senate Library, but soon resigning that position, returned to literature, edited a series of French classics for Alphonse Lemerre, the publisher of the contemporary poets, and became for a time a reader with that house. His work during this period, consisting of monographs on the classic writers of France, was collected and published as *Le Génie latin* (1913). In 1876, with *Les Noces corinthiennes*, came a second volume of verse, which revealed, like its predecessor, elegance without originality, a certain deftness of touch, a wide range of reading and interests, but little poetic inspiration. It was in prose, indeed, that France, as heir to the ironic tradition of Montaigne, Voltaire, Renan, was to find his true form of expression; in that medium, charged with satire, yet relieved throughout with pity and sympathy, was henceforward to be developed a philosophy of almost unrelieved scepticism. In 1879, as first attempts at fiction, appeared *Jocaste* and *Le Chat Maigre*, two short naturalistic novels, much inferior to later work, especially to their immediate successor, *Le Crime de Sylvestre Bonnard* (1881), which, crowned by the Academy, must be considered the first of France's masterpieces. Here, as in most of his stories, there is no continuous narrative, but a series rather of loosely connected sketches, essays, and meditations; through these, in a style charming as always in its harmony, grace, and rhythm, and in its studied simplicity and lucidity, is recorded with gentle irony the tale of Bonnard, the unworlly antiquarian, the earliest and certainly one of the most delightful of France's avatars. *Les Désirs de Jean Servien*, which followed in 1882, a novel of the naturalistic type, is one of the weakest of France's works, but *Abeille* (1883) is a pleasing fairy tale. *Le Livre de mon ami* (1885), an autobiographical account of early days, is an undoubted masterpiece in its kind, a

perfect fusion being contrived between the genuine impressions of childhood and the more critical reflections of maturity; hardly so successful in this manner were the sequels, *Pierre Nozière* (1899) and *Le Petit Pierre* (1918). In 1886 appeared *Les Enfants*, a collection of nursery stories, and for some years thereafter France's production was limited to short stories and to journalistic work in literary criticism. In the short story, as represented in the series *Balthazar* (1890), and in the later series *L'Étui de nacre* (1892), *Le Puits de Sainte-Claire* (1895), *Craquinville*, *Putous*, *Riquet* (1904), *Les Contes de Jacques Tournbroche* (1909), and *Les sept femmes de la Barbe-Bleue* (1909), France cannot compare with the great masters in that craft, though even the most indifferent are models in style. In literary criticism, however, his name ranks high, although he represents the type of critic who, maintaining the essential subjectivity of criticism, does not criticise, so universal is his curiosity, so catholic his taste, so absolute his scepticism as to rules, canons, and principles of literature. In *La Vie littéraire* (4 vols. 1888-92), a collection of his work in literary criticism, contributed to *Le Temps*, France appears as an unrivalled *causeur*, as a trained and erudite historian, as in part a gifted moral philosopher, while in these four volumes, perhaps better than in more formal works, are reflected the essential convictions of the author—his universal scepticism and irony; his purely human and naturalistic conception of the world; his code of ethics (later beautifully expressed in *Le Jardin d'Épicure*, 1894), based exclusively on freedom, sympathy, and pity; his hostility to the traditions and institutions which support supernaturalism, asceticism, and dogmatism; his open advocacy of the thought and even of the ethics of the 18th century. After 1892 France forsook literary criticism for fiction, and in *Thais* (1890), *La Rôtisserie de la reine Pédauque* (1893)—the sequel, *Les Opinions de M. Jérôme Coignard* (1893), is in important respects inferior—and *Le Lys rouge* (1894), embarked on the period of his greatest artistic achievement, a period which ended in his election to the Academy in 1896. *Thais*, the tale of an early Christian hermit, who in saving a courtesan lost his own soul, is written in the tone of the Lives of the Saints, and is the most carefully finished of his works; *La Rôtisserie de la reine Pédauque*, a pastiche perfect in its sustained imitation of 18th-century style, has no plot, though there is a connecting interest centring round the epicurean Abbé Coignard, who, in his delight in confounding human reason by the spectacle of its infirmities and contradictions, may be taken as a projection of France himself. In both works, only more openly in the second than in the first, superstition and asceticism are made the sport of destructive irony. *Le Lys rouge*, a novel of contemporary life, reveals France's style in unmatched pellucidity; here, as always, conversations are of the very essence of the story, and from the point of view of art, if not from that of ethics, universal tribute has been rendered to this work. To the literary life of France in the period following 1897, the Dreyfus case must be taken as the key. Under the influence of that crisis, sceptic though he was, and as a result, one must suppose, of the ascendancy of the pity and sympathy which had always tinged his scepticism, France became, from what might be termed a conservative anarchist, an open champion of free-thought and socialism. In the four volumes of *Histoire contemporaine—L'Orme du mail* (1897), *Le Mannequin d'osier* (1897), *L'Anneau d'améthyste* (1899), *Monsieur Bergeret à Paris* (1901)—the course of this evolution in his thought is to be traced. These volumes consist of a series of articles originally contributed to *Le Figaro*, but they are

articles of a kind which almost defy definition; sometimes they consist of a descriptive sketch with some of the elements of a short story, more often they are a commentary and mostly a satire on current events; in so far as a certain thread of narrative connects the whole, the various instalments may really be regarded as the chapters of a loose and rambling novel; thus *L'Orme du mail* is unique as a description of provincial life, *Le Mannequin d'osier* is a living picture of shabby gentility, while *L'Anneau d'améthyste* and its almost purely political sequel, *Monsieur Bergeret à Paris*, together form a bitter satire against the worldliness of the established church. Throughout the whole of the *Histoire contemporaine* it is in the life, character, and opinions of Professor Lucien Bergeret, a picture of France himself, that chief interest lies. In *Monsieur Bergeret à Paris* there are no more than hints of France's sympathy towards socialism, but shortly thereafter he definitely espoused that cause, and subsequently wrote and spoke much in its furtherance; *Opinions sociales* (1902) is an assemblage of his written views on questions social and economic; while *Vers les temps meilleurs* (1906) is a collection of his speeches on similar topics. Of the two stories in *Sur la pierre blanche* (1905), the second represents France's conception of a Utopia, but it is a Utopia essentially disappointing. Equally disappointing were the times in which the work appeared—no real political purification had followed from the Dreyfus case, the promises held out by socialism continued unfulfilled. In these circumstances disillusionment came to France. It was then that *La Vie de Jeanne d'Arc* (1909), an elaborate anti-clerical work, appeared, but more typical products of discouragement and cynicism were *L'Île des Pingouins* (1908), a pungent political satire on the vanity of human endeavour; *Les Dieux ont soif* (1912), an historical novel reflecting through Biotteaux des Islettes antagonism, on the part of the author, to the French Revolution, and *La Révolte des Anges* (1914), a novel chaotic in construction and anarchistic in philosophy. A pacifist prior to 1914, France nevertheless actively supported his country during the Great War with his pen, as in *Sur la voie glorieuse* (1915) and *Ce que disent nos Morts* (1916). Later he appeared as a somewhat sceptical apologist of bolshevism. In 1921 he was awarded the Nobel Prize in literature, and in 1922 appeared *La Vie en fleur*. He died 12th October 1924. The chief characteristics of France as a writer and his merits as a stylist have been indicated. Among his limitations are to be noted the essential formlessness of his longer works, a tendency to repetition, and a subjectivity which hampers his creative imagination, making his best characters no more than portraits of himself.

See works by G. M. C. Brandes (1908), G. Michaut (1913), Y. Giraud (1914), W. L. George (1915), and L. P. Shanks (1919); also A. L. Guérard in *Five Masters of French Romance* (1916). Most of France's works have been translated into English; his table-talk, collected and recorded by P. Gsell, appeared in translation as *Anatole France and his Circle* (1922).

Francesca da Rimini, the beautiful daughter of Giovanni da Polenta, lord of Ravenna, was given in marriage to Giovanni the Lama, son of Malatesta, lord of Rimini, on the conclusion of peace between the two houses. But her heart was already given to Paolo, Giovanni's brother; and in 1285 Giovanni, surprising the two lovers together, slew them both. The incident is woven into the *Inferno* of Dante. See Leigh Hunt's poem, D'Annunzio's tragedy, and Yriarte, *Françoise de Rimini dans la Légende et dans l'Histoire* (Paris, 1882).

Francesco di Paula, or **St Francis of Paola**, founder of the order of the Minims, was born in 1416 at Paula or Paola, a village of Calabria. At the age of thirteen he was the inmate of a Franciscan convent; and at nineteen he retired to a cave where he inflicted on himself every species of self-mortification. The fame of his piety having attracted to his cell several emulators of his austere life, he obtained permission to erect a convent, and the new community received from Pope Sixtus IV. the title of the Hermits of St Francis of Assisi; but the title was changed by Alexander VI. to Minim-Hermits of St Francis of Paola. The founder established numerous communities in Italy, Sicily, France, Spain, and Germany, but the Minims were never settled in Great Britain or Ireland. To the usual conventual vows, Francesco added one of the most rigorous abstinence—flesh, eggs, cheese, and milk being strictly forbidden the entire year, except in illness. Popular report having attributed to Francesco several wonderful cures, Louis XI. of France, being ill, summoned him to his presence. Francesco was received with the highest honour, and attended the king on his death-bed. Charles VIII. and Louis XII. induced him to settle in France, and built him convents at Plessis-les-Tours and Amboise. Francesco died at Plessis on Good Friday 1507, and was canonised in 1519.

Franceville, a military station in French Congo or Gabun (q.v.), founded by De Brazza in 1881 on the Ogowe, near where the Passa enters it.

Franche-Comté, province of E. France, in the Rhone basin, corresponded to the former County of Burgundy, and comprised Doubs, Haute-Saône, and Jura departments. Capital, Besançon.

Francia (1450-1517), a Bolognese painter whose real name was Francesco Raibolini. Originally a goldsmith, medallist, and artist in niello-work, he became famous as a religious painter, influenced mainly by Perugino and Raphael. See C. G. Williamson, *Francia* (1900).

Francia, **JOSÉ GASPAR RODRIGUEZ**, usually called Dr Francia, Dictator of Paraguay, was the son of a small landed proprietor, of French or Portuguese origin, and was born near the town of Asuncion about 1757. He studied theology at the university of Córdoba, took his degree as doctor of theology, and was for some time a professor in that faculty. Next he adopted the profession of law, and practised for thirty years, earning a high reputation. He was past fifty when the revolution which shattered the Spanish yoke in South America broke out in Buenos Aires. Paraguay at first offered active opposition to the revolutionists, but ultimately sought to obtain independence for itself. Francia took a leading part in the movement, and on the declaration of independence in 1811 was appointed secretary of the first national junta. Two years later, under a new constitution, he was elected one of the two supreme consuls. Francia was himself virtually sole ruler from the first, and in 1814 was appointed dictator for three years. At the expiry of that time the dictatorship was given him for life, and the absolute control so conferred he exercised until his death in 1840. Under Francia's firm rule the condition of Paraguay rapidly improved, but the country went to ruin after his death. One characteristic of his government was a system of non-intercourse, political or commercial, with other nations. So strict were the regulations against foreign intercourse that ingress to or egress from Paraguay was next

to impossible; and Francia's treatment of some foreigners who did get in, among them the famous savant Bonpland, was harsh and barbarous. He was a complete despot throughout, but his aims were not purely selfish. He was unscrupulous in his choice of means, and became more violent as he grew older and as the east wind blew. Yet he improved agriculture, promoted education, repressed superstition as well as religion, and enforced strict justice between man and man in his law-courts, however little he regarded it for himself. And it is said that his death was regretted by the people as a public calamity. Francia is a solitary figure full of interest of a kind, but is after all a very mean example of the old Greek tyrant, and becomes absurd when posed as a great hero and patriot.

See Rengger and Longchamp's *Essai Historique*, &c. (Paris, 1827); Spanish Life by Bazán (1887); and *Francia's Reign of Terror* (Lond. 1839), by J. P. and W. P. Robertson, two young Scotsmen whom Francia turned out of the country. Carlyle's interesting *Edinburgh* essay (1843) must be read with caution, in view of its bias favourable to the dictator.

Francillon, **ROBERT EDWARD** (1841-1919), novelist, was born at Gloucester. Educated at Cheltenham and Cambridge, and called to the bar in 1864, he was on the *Globe* newspaper from 1872 to 1894. *Grace Owen's Engagement*, a first novel, appeared in *Blackwood's Magazine* in 1868. Among later works were *Olympia* (1874), *A Dog and his Shadow* (1876), *King or Knave* (1888), *Jack Doyle's Daughter* (1894), *Mid-Victorian Memories* (1913).

Francis, **SAINT**. See FRANCIS OF ASSISI.

Francis I., king of France, son of Charles, Comte d'Angoulême, was born at Cognac, September 12, 1494, and succeeded Louis XII., his uncle and father-in-law, January 1, 1515. His first act as king was to reconquer Milan, which had been wrested from his predecessor two years before. Crossing the Alps by an unguarded pass, he attacked the Swiss mercenaries in the Milanese at Marignano (13th September 1515), and obtained a complete victory—the Swiss losing 12,000 men. In December 1516 he signed a concordat with the pope, which virtually broke down the independence of the French national church. On the death of Maximilian, emperor of Germany, in January 1519, Francis became a candidate for the imperial crown. But the election of Charles of Spain (henceforward known as Charles V., q.v.) provoked Francis to a declaration of war against him, though, in spite of all the splendours of the 'Field of the Cloth of Gold' near Calais (1520), the French king had failed to secure for an ally Henry VIII. of England, who afterwards joined the pope and the emperor. The papal troops drove the French out of Italy; the soldiers of Henry and the emperor invaded France on the north; the Constable Bourbon deserted to the enemies of Francis; and the principal Italian republics declared against him. The French king, after presenting for some time a bold and successful front to his many adversaries, was totally defeated and taken prisoner at the battle of Pavia, 24th February 1525. Charles carried his captive to Madrid, and only granted him his liberty a year later, Francis being compelled to renounce the suzerainty of Flanders and Artois, the duchy of Burgundy, and all his Italian possessions and claims, to promise the restoration of Bourbon to his former dignities, and to surrender his two sons as hostages. No sooner, however, did he regain his freedom than he induced Pope Clement VII. to absolve him from his oath; and England, Rome, Venice, Florence, and Genoa—all of whom were growing alarmed at the immense power of Charles—withdrawing from their alliance with the latter, and siding with his antagonist, the war in Italy

recommenced. On 5th May 1527 Bourbon's 'black banditti' stormed and sacked the Eternal City, and captured the pope. On the other side a French army was frittered away before Naples, having accomplished nothing. At last a peace was concluded at Cambrai, in July 1529, by which Francis retained Burgundy, but lost the Milanese, Flanders, and Artois. Hostilities were again renewed in 1534; yet, as before, only little was accomplished. The war was, however, marked by an alliance between Francis and the Turks, a proceeding which excited the indignation of Christendom. By the efforts of Pope Paul III., another treaty was concluded for ten years at Nice between Charles and Francis, 18th June 1538. Charles V.'s unfortunate expedition against Algiers once more stirred up the French king to renew the quarrel (1542), and he launched five different armies against the emperor. In spite of the battle of Cérisolles (14th April 1544), in which the French were completely victorious, Charles and his ally, Henry of England, marched upon Paris, and Francis was compelled to make peace at Crespy (18th September 1544), matters being left *in statu quo*. Francis died at Rambouillet, March 31, 1547. Superficially a man of brilliant parts, Francis had in reality at bottom a frivolous, changeable, licentious nature. Nevertheless he greatly fostered learning and art, inviting painters and scholars to his kingdom, founding libraries, opening schools, and building several of the finest palaces in France; but his persecution of the Vaudois and other Protestant sects has left a dark stain on his memoirs which all his patronage of artists and men of letters will not efface. See FRANCE; Cochrane, *Francis I. and other Studies*; Pardoe, *Court and Reign of Francis I.* (new ed. 3 vols. 1887); G. Paris, *Francis I.* (1888); Coignet, *Francis I.* (trans. 1889); H. Hauser, *Les Sources de l'histoire de France* (ii. 1909); also CHARLES V., and works there cited.

Francis I. (1708-65), emperor of Germany, was the eldest son of Leopold, Duke of Lorraine, and Grand-duke of Tuscany. In 1736 he married Maria Theresa (q.v.) of Austria. See AUSTRIA.

Francis II., emperor of Germany, and I. of Austria, was born at Florence, 12th February 1768, and in 1792 succeeded his father, Leopold II. The reign of Francis may be summarised as a series of wars against Napoleon, in which, except in the last, he was worsted. The first contest was that terminated by the Peace of Campo Formio in 1797, when Austria lost the Netherlands and Lombardy, receiving in return Venice, Dalmatia, and Istria; the next that in which Austria, after the great reverses of Marengo and Hohenlinden, was compelled to sign the Treaty of Lunéville in 1801. Then followed the short campaign of 1805, in which the defeat of the Russians at Austerlitz left Austria no alternative but to purchase peace at Presburg by the cession of Venetia, Tyrol, and Vorarlberg. In the following year, on the foundation of the Confederation of the Rhine, Francis renounced the title of German-Roman emperor, and contented himself with that of emperor of Austria, which he had already assumed in 1804. In 1809 another futile attempt to break the power of Napoleon again ended in disaster, Austria losing by the Treaty of Vienna (1809) the provinces of Salzburg and Carinthia, also Villach, Görz, Trieste, and a part of Croatia, Dalmatia, and Galicia. Then, after a short alliance with France, the emperor once more assailed his western antagonist; and this time, in conjunction with the Russians and Prussians, Austria won the battle of Leipzig (1813), and helped to complete the first overthrow of Napoleon. By the Treaty of Vienna (1815) Francis recovered his

possessions in Lombardy and Venetia and Galicia. This success was probably due almost entirely to Metternich, who became virtual ruler of Austria in 1809. Francis was a type of the absolute despot who rules in such a way as to promote what he conceives to be the welfare of his subjects. His internal policy was, however, marked by the suppression of all liberal views in politics and in intellectual life, by a jealous concentration of political power in the hands of the emperor and his minister, and by a rigid adherence to the conservatism of the past. Although narrow in both mind and sympathy, Francis was a popular ruler, owing to his urbanity of manner and the simplicity of his courtly life. He died on 2d March 1835, and was succeeded by his son Ferdinand I. See Meynert, *Franz I.* (2 vols. Vienna, 1871-73).

Francis, JOHN, publisher of the *Athenæum* for half a century, was born in 1811. In August 1831 he entered the *Athenæum* office as a clerk, and two months later became its publisher, a position he held till his death, 6th April 1882. Francis took an active part in the movement for the repeal of advertisement duty on newspapers, as also the compulsory stamp and paper duty. The 'John Francis Pensions' were established by the News-vendors' Benevolent Institute, as a memorial of him. See *John Francis, publisher of the Athenæum*, by J. C. Francis (2 vols. 1888).

Francis, SIR PHILIP (1740-1818), son of the Rev. Dr Francis, was born in Dublin. Leaving Ireland at twelve, he entered St Paul's School in London about the same time as Woodfall, afterwards editor and printer of the *Public Advertiser*. At sixteen Francis was appointed a junior clerk in the secretary of state's office, of which Henry Fox was the head, to whose family Dr Francis had acted as tutor. In 1758 Francis was secretary to General Bligh on his expedition against Cherbourg; in 1760 he was Lord Kinnoul's secretary during a mission to Portugal; in 1761 he acted as amanuensis to the elder Pitt, and in 1762 he was made first-clerk in the War Office by Welbore Ellis, then secretary at war. In December 1771 Francis was offered the post of deputy-secretary by Lord Barrington, which he declined, resigning his clerkship in the following March. In June 1773 he was nominated by Lord North, on Lord Barrington's recommendation, a member of the Council of Bengal. Always at enmity with Warren Hastings, he fought a duel with him on the 17th of August 1780, and was seriously wounded. In 1781 he returned home with a fortune largely acquired by playing whist with Mr Barwell, his colleague. He entered parliament in 1784 as member for Yarmouth in the Isle of Wight, afterwards sitting for Appleby till 1807. He was energetic in the proceedings against Hastings. He wrote many pamphlets. His ambition was to be governor-general of India; he received a knight-companionship of the Bath. He was devoted to the prince-regent, and a warm supporter of the 'Friends of the People.' In 1816 Mr John Taylor sent forth a book identifying Francis with Junius, but Francis never acknowledged having written the *Letters*. His young second wife, whom he married when seventy-four, was convinced that he must be Junius. No indisputable proof that Francis was Junius has yet been made public (see JUNIUS, and works there cited). See *Memoirs of Sir Philip Francis*, by Parkes and Merivale (1867), and *The Francis Letters* (ed. B. Francis and E. Keary, 1900).

Franciscans, also called MINORITES or LESSER BRETHREN, a religious order of the Roman Catholic Church, founded in 1208 by St Francis of Assisi (q.v.). Some idea of the extraordinary extension

of this remarkable institute may be formed from the startling statement that, in the dreadful plague of the Black Death in the following century, no fewer than 124,000 Franciscans fell victims to their zeal for the care of the sick and for the spiritual ministration to the dying. But this marvellous external progress was accompanied by serious internal controversies and divisions. In the original scheme of the institute its great fundamental characteristic was poverty, which St Francis proposed to render in his order not only more perfect theoretically, but more systematic in its practice, than in any of the contemporary institutes. For the accomplishment of this design, the rule which he drew up contained a few brief and simple provisions. But the difficulty of their literal observance led, even in the lifetime of St Francis, to an attempt in the general assembly of the order to introduce some important modifications; and, though the authority of the founder was sufficient to prevent the adoption of these modifications during his lifetime, and although his last will contained a special clause prohibiting all change of the rule, the attempt was renewed with still more determination under Brother Elias, his successor in the office of general of the order. The great subject of controversy was the nature and extent of the obligation of religious poverty, as vowed in the order. Francis desired that it should be understood in the most rigorous sense; and, in his scheme of poverty, neither the individual brethren nor the community could acquire or retain any right of property even in things of necessary use. The rigorous party in the order sought to carry out this principle to the fullest extent; contended that it was unlawful for the order to acquire a right of property in houses, convents, or even churches; and restricted their right in everything which they possessed to the simple use. Several successive popes sought, by explanatory decrees, to settle the dispute; and for a time a compromise was received, by which it was understood that the right of property in all *de facto* possessions of the order was vested in the see of Rome; but the foundations of the real controversy lay deeper than this. They regarded the practice, far more than the theory, of poverty; and the disputes to which they led issued not only in the formation of fresh offshoots from the body in the new religious orders to be named hereafter, but also in a large, and, for a time, formidable, secession from the church in the sect of the Fraticelli (q.v.).

The supreme government of the Franciscan order, which is commonly said to be the especial embodiment of the democratic element in the Roman Catholic Church, is vested in a minister-general elected for six years, who resides at Rome. The subordinate superiors are the 'procurator-general,' the minister-general's substitute in case of absence from Rome or vacation of office; the 'minister-provincial,' who presides over all the brethren in a province; and the *custos* or 'guardian' (not called 'abbot'), who is the head of a single convent or community. The provincial alone has power to admit candidates, who are subjected to a novitiate or probation of two years; after which they may, if approved, take the vows of the order. Members advanced to holy orders undergo as 'scholars' a preparatory course of study; and if eventually promoted to the priesthood they are styled 'fathers' of the order; the title of the other members being 'brother' or 'lay-brother.'

A very important feature, however, of the organisation of the Franciscan, as it subsequently became of other orders, is the enrolment of non-conventual members, who continue to live in society without the obligation of celibacy; and in general are bound only by the spirit, and not the letter, of

the rule. They are called 'Tertiaries' or members of the Third Order of St Francis. It is impossible to overestimate the value of this institution in the disorganised social condition of that age. The Tertiaries were bound, as the very first condition of enrolment, to restore all ill-gotten goods; to be reconciled with all those with whom they had been at feud; to devote themselves to the practice of works of Christian charity; to avoid all unnecessary expenditure; to renounce the use of personal ornaments; to hear mass daily; to serve the sick and the hospitals; to instruct the ignorant; and, in a word, to practise as far as possible in the world the substance of the virtues of the cloister. The institute in this form undoubtedly exercised a powerful influence in medieval society. It counted members in every rank, from the throne to the cottage; and, although it was in some instances deformed by abuses and superstitious practices, the aggregate results were undoubtedly beneficial.

The Franciscan order has been the parent of many other religious institutes. The earliest of these is that of the 'Observantists' or 'brethren of more strict observance,' called in France Cordeliers (q.v.). The party in the order which contended for the more rigid observance of the rule, after a protracted struggle—in which disaffection to the church itself was often strongly exhibited—obtained a separate organisation, which may be said to have been finally settled at the time of Leo X. The less rigid party, under the name of 'Conventuals,' obtained a distinct general, and an authorisation for their mitigated observance of the rule. Their churches and convents admit greater richness of architecture and decoration; and they are at liberty to acquire and retain, in the name of the order, the property of these and similar possessions, all of which are renounced by the Observant Franciscans. The latter community comprises nearly 100 provinces. Their constitution is that of the original rule, as already explained. A second offshoot of the Franciscan order, and in the same direction of rigorism, is that known as the 'Capuchin,' founded by Matteo di Basio, a Franciscan brother of the Observant rule, in the early part of the 16th century. Believing himself divinely called to revive the old spirit of his order, and learning that the modern habit of the brethren was different from that of St Francis, he began with externals, and procured for himself, and obtained the papal permission to introduce (1528), the peculiar habit, with a pointed hood or cowl (*capuche*), from which the name of the reformed order is derived. Along with this habit, however, Matteo adopted a very rigorous and mortified course of life, in which he was joined by others of the brethren; and the reform spread so rapidly among the community that in the year 1536 a general chapter of the new congregation was held. They were subject, however, to the jurisdiction of the general of the Franciscan order. One of the first generals of the new reform was Bernardino Ochino, afterwards notable by his defection to Calvinism. After the Council of Trent the Capuchins multiplied rapidly, though they were not introduced in France till the end of that century. A similar reform, to which the name of 'Recollets' was given (introduced in Spain by John of Guadalupe in 1500), was approved by Clement VII. in 1532; and many of the new brethren were among the first Spanish missionaries to the New World. A further development of the rigoristic spirit is the congregation of 'Discalced' or 'Barefooted' Franciscans. The author of this reform was a Spanish Capuchin, Peter of Alcantara. In his capacity of provincial of Estremadura, Peter introduced many reforms, and in 1555 obtained the approval of Pope Julius III. for a new rule, which was afterwards confirmed by Pius IV.

The notice of the Franciscan institute would be incomplete without the mention of the several orders of nuns; as those of St Clare (q.v.) or Poor Clares, the Capuchinesses, the Urbanist nuns, &c., which formed part of the same general organisation. None of these, however, presents any very peculiar features.

The Franciscan order in these several branches has at all times maintained its popularity in the Roman Catholic Church. When Helyot, in the beginning of the 18th century, published his great *Histoire des Ordres Religieux*, the Franciscan order numbered nearly 120,000 friars, distributed over above 7000 convents, and nearly 30,000 nuns, occupying about 900 convents. Since the French Revolution the number has of course been very much diminished, the order having been suppressed in more than one state; but it is still one of the most numerous in the Roman Catholic Church. Many of the foreign missions are mainly supplied by Franciscans, and they possess convents in almost every part of the world. They were preaching in Morocco, Armenia, and China before the end of the 13th century; in Abyssinia and on the Congo in the 15th; and in the 16th were active in Mexico and elsewhere in America.

As a literary order the Franciscans have chiefly been eminent in the theological sciences. The great school of the Scotists takes its name from John Duns Scotus (see DUNS), a Franciscan friar, and it has been the pride of this order to maintain his distinctive doctrines both in philosophy and in theology against the rival school of the Thomists, to which the Dominican order gave its allegiance (see AQUINAS). In the Nominalistic controversy the Thomists were for the most part Conceptualists; the Franciscans adhered to rigid Realism (see NOMINALISM). In the Free-will question the Franciscans strenuously resisted the Thomist doctrine of 'predetermining decrees.' Indeed, all the greatest names of the early Scotist school are the Franciscans, St Bonaventure, Alexander of Hales, and William of Ockham, the latter two, like Scotus himself, British theologians. The single name of Roger Bacon, the marvel of medieval letters, the divine, the philosopher, the linguist, the experimentalist, the practical mechanician, would in itself have sufficed to make the reputation of his order, had his contemporaries not failed to appreciate his merit. Two centuries later the great Cardinal Ximenes was a member of this order. The Popes Nicholas IV., Alexander V., Sixtus IV., the still more celebrated Sixtus V., and Clement XIV., also belonged to the institute of St Francis. In history this order is less distinguished, except for its own annalist, Luke Wadding (q.v.). In poetry we have St Francis himself. Jacopone da Todi is one of the most characteristic of mediæval hymn-writers; and in later times Lope de Vega closed his eventful career as a member of the Third Order of St Francis. In the revival of art the Franciscan order bore an active and enlightened part.

The first Franciscans reached England in 1220, and founded monasteries at Canterbury and Northampton. They made rapid progress; at the dissolution there were sixty-five Franciscan monasteries in England. The order was restored by the foundation of the English convent at Douay in 1617.

Francis de Sales. See FRANCIS OF SALES.

Francis Joseph, emperor of Austria, king of Hungary, born 18th August 1830, the eldest son of the Archduke Francis (son of the Emperor Francis I.), came to the imperial throne in 1848 as the successor of his uncle Ferdinand I., who had been forced to abdicate (see AUSTRIA). His first task was to subdue the Hungarian revolt, and to effect the pacification of Lombardy. This accomplished, an era of reaction began. The national aspirations of the various ethnic constituents of the empire for political autonomy and freedom were rigorously suppressed, and a determined effort made to fuse them into one state, the nucleus and support of which should be the army; the emperor reasserted his claim to rule as an absolute sovereign; the policy of bureaucratic centralisation was again reverted to; and a close alliance was entered into with the Roman Catholic party to combat the advocates of liberal progress. In 1859 Lombardy was ceded to Sardinia; and by the war with Prussia in 1866 Austria was excluded altogether from Germany. At the same time she was compelled to hand over Venetia to the king of Sardinia, who had fought as the ally of Prussia. From this time a change came over the policy of Austria. The emperor thenceforward adopted a policy of conciliation towards the nationalities comprised in his dominions, and appeared especially desirous of gratifying Bohemia. In 1908 he annexed Bosnia-Herzegovina, which had been under Austro-Hungarian administration since 1878. By the death of his only son Rudolf (1858-89), Francis Ferdinand, son of the emperor's brother Karl Ludwig, who renounced his claims to the throne, became heir-presumptive. His assassination at Sarajevo (28th June 1914) was the immediate cause of the outbreak of the Great War. Francis Joseph died 21st November 1916, and was succeeded by Karl, a grandson of Karl Ludwig.

Francis of Assisi, founder of the Franciscan order, and a saint of the Roman Catholic Church, was one of the most extraordinary men of his age, illustrating in his career all the most remarkable characteristics of the religious life of the middle ages. He was born in 1182, of a family called Bernardone, at Assisi, where his father was engaged in trade. His baptismal name was John; but from his familiarity in his youth with the Romance, or language of the troubadours, he acquired the name of *Il Francesco* ('the little Frenchman'). In his early years he was remarkable for his love of gaiety and ostentatious prodigality; but even then his bounty to the poor was one of the largest channels of his wastefulness. He engaged eagerly in exercises of chivalry and of arms; and in one of the petty feuds of the time he was taken prisoner, and detained for a year in captivity at Perugia. An illness there turned his thoughts from earth; and, although he again engaged in military pursuits, a second illness at Spoleto decided his career for life. He now resolved to fulfil literally the counsels of the gospel, and he especially devoted himself to poverty, which, in the mystic language thenceforth familiar to him, he designated as 'his bride'; and he took a vow never to refuse alms to a beggar. He exchanged clothes with a poor mendicant; and, disregarding all remonstrance and ridicule, he ever afterwards continued to wear the meanest attire. He gave to a priest who was rebuilding a ruined church the price of his horse, which he sold for the purpose, and even sought to appropriate to the same use the moneys of his father, which, however, the priest refused to accept. To avoid his father's anger he took refuge in a cave, in which he spent a month in solitary prayer. His father, having in vain confined him in a dark room of his own house, cited him before the magistrates, and, on Francis's declining all civil

jurisdiction in such a case, before the bishop, in order to compel him to renounce his inheritance. Francis abandoned all, even to the very clothes he wore, and then declared 'till now he had been the son of Bernardone, but that henceforth he had but one Father, Him that is in heaven.' Thenceforth no humiliation was too low for Francis; he begged at the gates of monasteries; he discharged the most menial offices; he served the lepers in the hospital at Gubbio with the most tender assiduity. He worked with his own hands at the building of the church of St Damian, and at that of Sta Maria degli Angeli, which he afterwards called his 'Portiuncula,' or 'little inheritance;' and as the last act of self-spoilation, and the final acceptance of the gift of poverty, he threw aside his wallet, his staff, and his shoes, and arrayed himself in a single brown tunic of coarse woollen cloth, girt with a hempen cord. This was in his twenty-sixth year, in 1208. His enthusiasm by degrees excited emulation. Two of his fellow-townsmen, Bernard Quintavalle and Peter Cattano, were his first associates. They were followed, although slowly, by others; and it was not till 1210 that, his brotherhood having now increased to eleven in number, he drew up for it a rule, selected by thrice opening at random the gospels upon the altar, and taking the passages thus indicated as the basis of the young institute. The new brethren repaired to Rome, where their rule was approved at first only orally by Pope Innocent III. in 1210. The two following years were spent by the brotherhood in preaching and exhorting the people in various rural districts; and Francis, returning to Assisi in 1212, finally settled the simple constitution of his order, the church of Sta Maria degli Angeli being assigned to them as their home.

In common with the older forms of monastic life, the Franciscan institute is founded on the three vows of chastity, poverty, and obedience; but of these the second was, in the eyes of Francis, the first in importance and in spiritual efficacy. In other orders the practice of poverty consisted in the mere negation of riches. With Francis it was an active and positive principle. In other orders, although the individuals could not possess, it was lawful for the community to hold property in common. Francis repudiated all idea of property, alike for his order and for its members; he even disclaimed for them the property in those things which they retained for personal use—the clothes which they wore, the cord with which they were girded, the very breviary from which they chanted the divine office. The very impossibility, to human seeming, of these vows, was their strength. Numbers crowded to the standard of Francis. He told them off in parties to different provinces of Italy. Five of the brotherhood repaired to Morocco to preach to the Moors, and, as the first martyrs of the order, fell victims to their holy daring. Success removed all the hesitation with which the institute at first was regarded, and in 1216 the order was solemnly approved by Pope Innocent. From this date it increased with extraordinary rapidity. At the first general assembly, held in 1219, 5000 members were present; 500 more were claimants for admission. Francis himself inaugurated the future missionary character of his brotherhood by going (1223) to the East, and preaching the gospel in the presence of the sultan of Egypt himself; but the only fruit of his mission was a promise from the sultan of more indulgent treatment for the Christian captives, and for the Franciscan order the privilege which they have since enjoyed as guardians of the Church of the Holy Sepulchre. It is after his return to Italy that his biographers place the celebrated legend, which, to friends or to enemies, has so long been a subject of veneration

tion or of ridicule—his receiving, while in an ecstasy of prayer, the marks (*stigmata*) upon his own person of the wounds of our Divine Redeemer. The scene of this event is laid on Monte Alverno, a place still sacred in the traditions of the order; and the date is September 17, 1224. Two years later St Francis died, October 4, 1226. On the approach of his last hour he requested that he should be carried upon a bier to the church, where he had himself placed on the bare ground, thus realising in his death the doctrine which he had made in life the basis of his system. He was canonised by Pope Gregory IX. in 1228.

The works of St Francis (folio, 1739) consist of letters, sermons, ascetic treatises, proverbs, moral apothegms, and hymns. The latter are among the earliest metrical specimens of the Italian language. They are exceedingly simple, and full of the tenderest expressions of the love of God. His prose is often more poetical than his poetry itself, abounding in allegory and poetical personification. Few writers have ever turned the love and admiration of external nature to a purpose so beautifully devotional. 'Of all the saints,' says Dean Milman, 'St Francis was the most blameless and gentle.' No saint, it may be added, has been the subject of more exaggerated panegyric from the writers of his order: one work—a parallel between St Francis and Christ—is disowned by the Roman Catholic community as a most reprehensible exaggeration, the fruit of an affectionate but most misdirected zeal.

See FRANCISCANS; also the Bollandist *Acta Sanctorum* for October 4; St Bonaventure, *Life of St Francis*, Butler, *Lives of the Saints*; Milman, *Latin Christianity*, Hase, *Franz von Assisi* (1856); Mrs Oliphant, *Francis of Assisi* (1871); books by Alemany (New York), Chérancé (trans. 1887), Le Monnier (2 vols. 1889; trans. 1894), Sabatier (trans. 1894), Canon Knox Little (1897), Tamassia (trans. 1911), Jorgensen (trans. 1912), Father Cuthbert (1912 and 1915), G. K. Chesterton (1923).

Francis of Paola. See FRANCESCO DI PAOLA.

Francis of Sales, a distinguished Catholic saint, was born August 21, 1567, at the family castle of Sales, near Annecy, in Savoy. He was the heir of the family honours, and his education was designed by his father to fit him for a career of distinction. From the provincial colleges of La Roche and Annecy he was sent to Paris in 1580, where he entered the then brilliant school of the Jesuits. In 1588 he went to Padua to read canon and civil law, and pursued his studies there with great distinction till 1591. At this time his father, who had obtained for him a place in the senate, proposed to him a very brilliant and advantageous marriage; but he had already resolved to devote himself to the priesthood, and with difficulty obtained his father's consent to enter into orders in the diocese of Geneva. He soon became distinguished as a preacher. Very soon after his ordination he was employed by his bishop in a mission for the conversion of the Calvinistic population of Chablais, which had been recently annexed to the duchy of Savoy. The success of this mission was almost unprecedented. One of the most remarkable incidents of his mission was a conference with the celebrated Calvinist leader, Theodore de Beza. At the termination of this mission, Francis was in 1598 appointed coadjutor to the Bishop of Geneva, Mgr. Granier, with the title of Bishop of Nicopolis. It was with much difficulty that the pope, Clement VIII., induced him to accept this dignity. In 1602, having occasion to go to Paris, he was invited to preach the Lent in the chapel of the Louvre; and his lectures were reputed to have had so much influence in bringing about the conversion of several Huguenot nobles, that the king tried to induce him to accept a French bishopric, but in vain. Mgr. Granier died

before the preacher's return to the diocese, whereupon Francis succeeded to the bishopric of Geneva. His administration of this charge was beyond all praise. Being invited to preach the Lent at Dijon, he was once more pressed to accept a French bishopric. But he still declined this honour—but it is not the fact (as has been sometimes asserted) that he declined a cardinalate. It was about this time that he published his well-known *Introduction to a Devout Life*, which has continued to the present day one of the most popular manuals of piety and the ascetic life. Among his measures for the renovation of the monastic spirit, a very important one was the establishment of a congregation of nuns of the order of the Visitation, under the direction of Madame de Chantal, with whom he long maintained a correspondence on every subject connected with the spiritual and religious life, published in 1625. In 1620 his brother Jean François was given him as a coadjutor in the charge of his diocese. He continued, however, to labour to the last. His last sermon was delivered at Lyons on Christmas-day in 1622; on 27th December he was seized with paralysis, and on the 28th of the same month he expired. His remains were immediately translated to Annecy; and in 1665 he was solemnly canonised as a saint by Alexander VII., his festival being held on January 29.

His works were published in a collected form in 2 vols. folio at Paris in 1641, and by Migne in 9 vols. 1861-64; a new edition by Dom Benedict Mackey was issued in 1891-1912. The separate works (especially the *Devout Life*) have passed through innumerable editions and translations. There are French Lives by De Sales, Haimon, and Perennes (often reprinted), and in English by Lear (new ed. 1880). And see a book by Guillot (1873).

Francis Xavier. See XAVIER.

Franck, CÉSAR, composer, organist, and teacher, was born 10th December 1822 at Liège, studied at the conservatory there, and from 1837 at that of Paris, where he was the pupil of Leborne for counterpoint and fugue, of Zimmermann for the pianoforte, and of Benoist for the organ, and gained a prize by a feat of transposition at sight. After teaching a while in Belgium, he returned to Paris as a teacher of the pianoforte. He was organist for many years at Ste. Clotilde, and in 1872 succeeded Benoist as professor of the organ at the Conservatoire. He was naturalised a Frenchman next year. He died 8th November 1890. Franck was a hard-working musician of genius. Ten hours a day given to teaching yet allowed him time for a great body of serious and sincere composition. He did not become widely famous till his appointment to the chair at the Conservatoire. About that time his cantata *Ruth*, unsuccessful some twenty-five years earlier, attracted notice. *La Rédemption* increased his renown in 1873; and was followed by *Rebecca*, a biblical idyll; *Les Béatitudes*, an oratorio, thought by some to be his best work; a number of symphonic pieces (*Le Chasseur Maudit*, *Les Djinns*, &c.); a symphony in D; much church and chamber music; and two posthumous operas, *Hulda* and *Ghisèle*. Belgian-born, of German family and character, Franck powerfully influenced the younger French musicians. Like Bach an organist, he often reminds one of Bach. See a book by his pupil Vincent d'Indy (Eng. trans. 1909).

Franck, SEBASTIAN, one of the earliest masters of German prose, was born at Donauwörth in 1499, and became a pietist. Converted to Protestantism, he showed the bent of his mind in a *Treatise against the Horrible Vice of Drunkenness* (1528). But his insistence upon a moral reform in men's lives as being more important than a reform of dogma soon caused him to drift away from the school of Luther, and in 1531 he was banished from Strasburg, largely because of his advocacy of religious toleration in

his *Chronica*, probably the first attempt at a universal history in the German tongue. Thereupon Franck settled in Esslingen as a soap-boiler, but in 1531 removed to Ulm, where he took up the calling of printer. The publication of his *Paradoxa* in 1534 was the ultimate cause of his expulsion from that city in 1539. He died in 1542 at Basel. Franck also published *Weltbuch: Spiegel und Bildnuss des ganzen Erdbodens* (1534), *Chronica des ganzen teutschen Lands* (1538), *Die guldene Arche* (1539), and one of the earliest collections of popular proverbs in German in 1541. His historical writings, although distorted by mystic fancies, and from the modern point of view uncritical, are nevertheless distinguished for their justness and love of truth. See works by Bischof (1856), Hase (1869), Weinkauff (1877), Haggenschmacker (1886), Löwenberg (1893).

Francke, AUGUST HERMANN (1663-1727), born at Lubeck, in 1692 became professor of Oriental Languages at Halle, in 1698 of Theology. A conspicuous Pietist and pupil of Spencer, he founded in 1695 at Halle a school for the poor, a pedagogium, a burgher school, a Latin school, a training seminary, and an orphanage, which last became the most important of them all.

Franco-German War. See FRANCE

Francolin (*Francolinus*), a genus of birds of the grouse family, Tetraonidæ, closely allied to

Gray Francolin (*Francolinus ponticerranus*).

partridges. They are distinctly Ethiopian and Oriental birds, but one handsome species, the Black Francolin (*F. vulgaris*), used to be found in Spain, Italy, and Sicily, whence it has been hunted out. In Cyprus it still occurs, and has its home in Asia Minor, Palestine, and farther east.

Franconia, a loosely connected aggregate of districts and territories lying chiefly within the basins of the Rhine, the Main, and the Neckar, the exact boundaries of which have varied at different periods of history. Strictly taken, the name seems to have come into general use as a politico-territorial designation in the end of the 9th century, to indicate the districts included within a line drawn from Cologne to Cassel, thence to the Fichtelgebirge, and further by way of Nuremberg and Spirens back to Cologne. This region was looked upon as the original home of the Frankish people, and as the centre of the Germanic empire; within its boundaries, and on its soil, the king of the Germans was for a long time both elected and crowned. It was, however, divided into two portions, East Franconia and Rhenish Franconia, the line of division between them coinciding, generally speaking, with the Spessart. The first duke in

(not of) Franconia was Conrad I., recognised in 906, but five years later elevated to the German throne. Shortly afterwards Franconia became immediately subject to the imperial crown, the dignity of duke being, it would seem, conferred or withheld at the emperor's pleasure. Meanwhile the region itself was split up into a great number of lordships, countships, and ecclesiastical domains, these last belonging in great part to the powerful bishops of Würzburg, Worms, Spire, Bamberg, and Mayence. In 1268, however, the bishop of Würzburg successfully asserted his claim to the title of duke in East Franconia, but it was a Franconia reduced to little more than the territory immediately subject to the bishop. In 1501 Maximilian I., when dividing the empire into circles, abolished Rhenish Franconia, and restricted the title Franconia to a circle nearly coterminous with the district included within a line drawn through Würzburg, Bayreuth, and Eichstätt. The name, however, ceased to be used officially from 1806 to 1837; in this latter year the three northern divisions of the kingdom of Bavaria (q.v.) were called Upper, Middle, and Lower Franconia.

Franco-tireurs ('free-shooters'), armed bands of French peasants and others that sprang into existence during the progress of the Franco-Prussian war. At first their military organisation was very imperfect; afterwards this defect was in some measure remedied, and they were even formed into regular corps. For the most part they carried on a guerilla warfare, attacking small detachments of the enemy, and cutting off foraging parties. At first they were not recognised by the Germans as having any military standing at all, and when captured they were shot; but after a time, when they co-operated with the regular French army, such recognition was accorded them.

Franecker, a handsome town of the Netherlands, province of Friesland, 9 miles WSW. of Leeuwarden by rail. It was formerly the seat of a university, founded in 1585, but abolished by Napoleon in 1810. Franecker possesses Elsinga's notable planetarium (1773-80). Pop. 8000.

Frangipani, an illustrious Roman house, whose authentic history goes back to 1014, and which played an important part in the quarrels of the Guelphs and Ghibellines in the 12th and 13th centuries. They fortified the Colosseum, and included the arch of Titus and part of the Palatine in their castles. One of the most notable of the family was Giovanni Frangipani, lord of Astura, who captured Conradin (q.v.) of Swabia in 1268, and delivered him to his enemies. A branch of the Frangipani still flourishes in the province of Udine. The Croatian family of the same name claim descent from the great Roman barons, but are really of Slav origin, their title being properly *Frankopan* ('Frank the lord').

Frankalmoign (Lat. *libera eleemosyna*, 'free alms'). See FEUDALISM.

Franken. See FRANCONIA.

Frankenberg, a manufacturing town of Saxony, on an affluent of the Mulde, 32 miles SW. of Dresden, has manufactures of cottons, woollens, and silk-stuffs, also dye-works, a cigar-factory, and a foundry. It possesses some technical schools. Population, 13,000.

Frankenhäuser, a town of Germany, in Thuringia, standing on the Wipper, 27 miles NNW. of Weimar, has brine-springs and a hospital. In the vicinity are the Kyffhäuser and Falkenburg with Barbarossa's Cave. Pop. 8000. Near Frankenhäuser, on 15th May 1525, the revolted peasants under Münzer were defeated by the Saxon, Brunswick, and Hessian troops.

Frankenstein, a town of Prussian Silesia, on an affluent of the Neisse, 37 miles SSW. of Breslau, has a large trade in corn, also joiners' workshops, and establishments for making straw hats and carriages. Pop. 9000.

Frankenstein, in the romance of that name, written in 1816-18 by Mrs Shelley (Mary Godwin) in imitation of the old German stories of the supernatural, is the mortal who, having by the resources of natural science created a being in the form of man, is tormented by the monster of his own creation. In popular usage the term Frankenstein itself is often inaccurately applied to any creation which proves a cause of anxiety or disaster to its author.

Frankenthal, a manufacturing town of Bavaria, in the Rhine Palatinate, 7 miles SW. of Worms by rail, and $3\frac{1}{2}$ W. of the Rhine by a canal. Its industries include a sugar-factory, machine and boiler works, a cork-cutting factory, a bell-foundry, and breweries, and it has a trade in wine, iron, and timber. A village existed here in the 8th century. Created a town in 1577, and shortly afterwards made a fortress, Frankenthal suffered severely in the Thirty Years' War; it was burned to the ground by the French in 1689, but rebuilt in 1697. Pop. 23,000.

Frankfort, the capital of Kentucky, is situated amid picturesque scenery on the Kentucky River, here crossed by a bridge, 29 miles NW. of Lexington, with a state-house, reformatory, and other institutions; pop. 10,000, trading in timber and manufacturing shoes, chairs, carriages, &c.—There is another Frankfort in Indiana, 45 miles NW. of Indianapolis; pop. 11,600.

Frankfort-on-the-Main (Ger. *Frankfurt-am-Main*), a wealthy commercial city in the Prussian province of Hesse-Nassau, formerly a free city, long famous as the place of election of the German emperors, and the seat of the Diet from 1816 till 1866, is situated on the right bank of the Main, 22 miles from its confluence with the Rhine at Mainz, and 112 SE. of Cologne by rail. Pop. (1800) 40,000; (1867) 78,000; (1875) 103,315; (1885) 154,513; (1900) 288,989; (1905) 334,978; (1910) 414,918; (1919) 433,002—mostly Protestants. The city has been much extended, and many handsome public and private buildings have been erected; but the oldest part still contains many narrow and crooked streets, with quaint, high-gabled houses. The fortifications have been replaced by ornamental promenades; the river is bordered by broad quays; and the ancestral house of the Rothschilds is now the solitary relic of the famous Juden-Gasse, the ghetto of Frankfort. The Roemer or town-house, a Gothic edifice of 1405-16, contains the Kaisersaal or imperial hall, where each newly-elected emperor held his public banquet, at which he was waited upon by the high officers of the empire. On the walls hang the portraits of the emperors from Conrad to Leopold II. The coronation took place in the cathedral of St Bartholomew (13th to 16th centuries), which also contains the chapel in which the Electors (q.v.) voted. The palace of the Prince of Thurn and Taxis (1730) was the meeting-place of the North German Diet from 1816 till 1866, while the Constituent Assembly of 1848-49 met in the church of St Paul. The Saalhof stands on the site of an earlier palace of the Carolingian kings; the chapel dates from the 12th century. The new exchange was opened in 1879, the opera-house in 1880, and there are several other imposing public buildings, besides museums, art-galleries, a public library, numerous churches, many charitable institutions, a university (1913-14), to which is attached an 'academy of labour' for the better education of leaders of the labour movement, and two conservatories of music.

One of the squares is adorned with a statue of Goethe, a native of the town; in another is the elaborate Gutenberg monument, commemorating the invention of printing. Frankfort is connected with the suburb of Sachsenhausen, on the left bank of the Main, by seven bridges (two railway bridges), the oldest of which was built in 1342. The city lies at the junction of seven railways, which since 1888 have converged in the new Central Station, one of the largest and handsomest in Europe; it is the focus of many important roads; and it has direct water-communication with the North Sea *via* the Main and the Rhine. The commerce has thus at all times been considerable; and in the 16th century the Frankfort spring and autumn fairs, now insignificant except as leather and horse markets, were among the most important in Europe. The chief articles of trade are colonial wares, iron and steel goods, leather, hides, skins, coals, wine, and beer. The manufacturing industry has largely developed since the town became Prussian. Sewing-machines and other machinery, chemicals, soap and perfumery, iron goods, straw and felt hats are among the chief manufactures. Its chief importance, however, is due to its position as one of the leading money-markets of the world.

Frankfort is said to owe its name to Charlemagne, who led his Franks across a ford here to attack the Saxons beyond the Main. It was early recognised as a suitable place for national meetings, and in 794 Charlemagne convoked a council here. From 843 till 889 it was the capital of the eastern Frankish kingdom. In 1257 Frankfort was made the first free city of the German empire, and it also became the most important. In 1356 Charles IV. confirmed by the 'Golden Bull' (carefully preserved in the city archives) the right, which it had enjoyed since the days of Frederick Barbarossa (1152), of being the place for the election of the German emperors. The city embraced the Reformation in 1530; and in 1558 certain of the Protestant princes of Germany issued a declaration known as the *Frankfort Recess* in favour of the Augsburg Confession. Frankfort lost its independence in the Confederation of the Rhine, and from 1810 till 1813 it was the capital of a temporary grand-duchy. It recovered its privileges as a free city in 1816; but in 1866, having espoused the Austrian cause in the seven weeks' war, it was seized by the Prussians (July 16th), a fine of 6,000,000 florins was imposed on it, and on October 18th it was formally incorporated with Prussia. The Peace of Frankfort, which ended the Franco-German war of 1870-71, was signed 10th May 1871 at the Swan Hotel (now swept away) by Prince Bismarck and Jules Favre. The French occupied Frankfort from 6th April to 17th May 1920.

Frankfort-on-the-Oder, a town of Prussia, in the province of Brandenburg, 51 miles ESE. of Berlin, is a handsome, well-built town, with three suburbs, one of which lies on the right bank of the Oder, and is connected with the remainder of the town by a wooden bridge. The university, founded in 1506, was in 1811 incorporated with that of Breslau. Three great fairs are held annually. The principal manufactures embrace machines, hardware, organs, chemicals, stoneware, sugar, tobacco, spirits, leather, and paper. The town has also iron-foundries, tanneries, and breweries. Its situation on a navigable river, connected by canals with the Vistula and the Elbe, has always made it a place of considerable commercial importance. Pop. (1875) 47,176; (1919) 65,055. It was a flourishing member of the Hanseatic League in the 14th and 15th centuries; since then it has been several times besieged and ravaged in war. At

Kunersdorf, 4½ miles E. of Frankfort, on 12th August 1759, Frederick the Great suffered a great defeat from the Russo-Austrian forces.

Frankincense (Lat. *tus* or *thus*; Gr. *libanotos*), a name employed to designate various fragrant resinous substances which diffuse a strong fragrance in burning, and are on that account used in certain religious services. The frankincense of the Jews, and also of the ancient Greeks and Romans, was chiefly or entirely the substance now known as *Olibanum* (q.v.), the produce of the genus *Boswellia* (q.v.). Several trees, however, of different orders, yield substances used as frankincense instead of olibanum, in different parts of the world, as several species of *Icea* and of *Croton* in America; and the common fir (see FIR) in Europe, the resinous product of which is the Common Frankincense of the pharmacopœias, although in the shops concrete American turpentine is very often sold under this name. It is used in the composition of stimulating plasters, &c. Burgundy pitch is made from it. It is a spontaneous exudation from the tree, hardening by exposure to the air, and generally of a whitish or pinkish colour, with a rather agreeable odour and a balsamic taste. See INCENSE.

Franking Letters. On the introduction of the uniform penny-postage on all inland letters in 1840, the privilege formerly enjoyed by peers and members of the House of Commons, and many official persons, of *franking*—i.e. of sending and receiving letters duty free—was finally abolished. The privilege was claimed by the House of Commons in 1660, but the claim was rejected by the Lords, when it came before them as a clause in the Act 12 Charles II. chap. 35. Nevertheless, the indenture deposited with the letters-patent appointing Henry Bishop postmaster-general in that year expressly allowed the free transport of all letters to or from the king, the great officers of state, and single inland letters of the members of parliament for that session only. The practice of franking letters seems, however, to have been carried on until it was expressly granted, and the beneficiaries of the privilege defined, by the Act 4 George III. chap. 24 (1764). By this statute each member of either House of Parliament was entitled to send free ten letters every day, not exceeding an ounce in weight each, to any place in the United Kingdom, and to receive fifteen. As it was not necessary that the letter should be either written by or to the privileged person, the privilege was greatly abused. All that was requisite was that the member should write his name or title on the corner of the letter. But from 1837 till the abolition of the privilege it was required that the whole address should be written by the member; that he should add not only his name, but the name of the post-town, and the day of the month; and that the letter should be posted on the day on which it was written or the following day, and in a post-town within 20 miles of which the person franking was then actually resident.

Frankland, Sir Edward, D.C.L., LL.D., K.C.B. (1897), chemist, was born near Lancaster in 1825, and was appointed professor of Chemistry in Owens College in 1851, Bartholomew's Hospital in 1857, the Royal Institution in 1863, the Royal College of Chemistry in 1865, and the Normal School of Science, South Kensington, in 1881 (resigned 1885). He propounded the theory of valency. He was made F.R.S. in 1853, a corresponding member of the French Academy in 1866. He collected many of his papers in *Experimental Researches in Pure, Applied, and Physical Chemistry* (1878), and published, in addition to manuals and lectures, works on lighting, sanitation, &c., besides sharing

Lockyer's researches in the atmosphere of the sun. He died in August 1899.

Franklin, the English freeholder of former times, who held his lands of the crown, free from any feudal servitude to a subject-superior. He is one of Chaucer's group, and his description in the prologue to the *Canterbury Tales* will keep his memory from ever being forgotten. It is the finest picture in our literature of the hearty old country gentleman. In later times the franklin seems to have fallen in dignity (cf. *Winter's Tale*, V. ii. 173), his position apparently corresponding to that of the well-to-do yeoman; yet Dr Johnson's remark that franklin is 'not improperly Englished a gentleman servant' was at no time accurate.

Franklin, capital of Venango county, Pennsylvania, on the Alleghany River, 123 miles by rail (65 direct) N. of Pittsburg, with iron and lumber industries, and oil refineries. Its chief trade is in petroleum. Pop. 10,000.—Franklin in Tennessee, 20 miles S. of Nashville, gives name to a great defeat of the Confederates, 30th November 1864.—For Franklin district of Canada, see NORTH-WEST TERRITORIES.

Franklin, BENJAMIN, youngest son and fifteenth child in a family of seventeen, was born in Boston, Massachusetts, 17th Jan. 1706. Equipped with such education as he could pick up in scant two years at a primary school, he was apprenticed at twelve to his brother James to learn the trade of a printer, at which he soon became notably expert. He had been there about three years when his brother established a newspaper called the *New England Courant*, which Benjamin, after assisting in the printing, was required to deliver to the subscribers. He so effectively repaired the deficiencies of his early education during the three or four years of his apprenticeship that he ventured to try his hand as a contributor to the columns of the newspaper, and with such success that, when his brother was arrested and imprisoned for a month by the Speaker of the Assembly for a too liberal exercise of his critical faculties, the management of the paper was confided to Benjamin. The younger brother presumed perhaps too much upon his success; and for this and other reasons, the relations of the two gradually ceased to be harmonious, and despairing of finding satisfactory employment elsewhere in Boston, Franklin sold some of his books for a little money, with the determination to try his fortune elsewhere. He finally drifted to Philadelphia, where he landed on the Market Street wharf one Sunday morning, a friendless lad of seventeen, with one dollar and one shilling only in his pocket. He was fortunate enough to find employment immediately with a printer who had very little knowledge of his business, and to whom therefore Franklin's expertness and ingenuity were not long in proving almost indispensable. Not many months elapsed before an accident secured him the acquaintance of Sir William Keith, the governor of the colony, who persuaded him to go over to England for the requisite material to establish himself in the printing business in Philadelphia, by the promise to advance what money he would need for this purpose, and also to secure to him the printing for the government. Franklin arrived in London on the 12th December 1724. Instead of the letters of credit he was authorised to expect were awaiting him there he discovered to his consternation that no one who knew Keith placed the smallest dependence upon his word, and a gentleman whose acquaintance he had made on the passage laughed at the idea of the governor giving a letter of credit, who, as he said, had no credit to give. Franklin soon sought and found employment in a London printing-house,

where he remained for the next eighteen months. He then returned to Philadelphia, where, in connection with a fellow-printer whose father advanced some capital, he established a printing-house for himself. His skill as a printer, his industry, his good sense and personal popularity ensured him prompt and signal success. In September 1729 he bought for a trifle the *Pennsylvania Gazette*, a newspaper then only three months old, and in its columns proceeded to lay the foundations of a reputation as a journalist to which he owes no inconsiderable portion of his distinction among men.

In the following year Franklin married his old love, Deborah Read, now a widow, a young woman of his own station in life, by whom he had two children, a son who died in his youth, and a daughter, Sally, who afterwards became Mrs Bache, a name since honourably associated with the history of American science. In 1732 he commenced the publication of what is still known to literature as *Poor Richard's Almanac*, which attained a circulation then unprecedented in the colonies. His contributions to it have been republished in many languages. In 1736 Franklin was appointed clerk of the Assembly, in 1737 postmaster of Philadelphia; and shortly after he was elected a member of the Assembly, to which body he was re-elected almost uninterruptedly until his first mission to England, previous to which he was promoted to the office of deputy postmaster-general for the colonies.

In 1746 he commenced those fruitful researches in electricity which gave him a position among the most illustrious natural philosophers. He exhibited in a more distinct form than heretofore the theory of positive and negative electricity; by his famous experiment with a boy's kite he proved that lightning and electricity are identical; and he it was who suggested the protecting of buildings by lightning-conductors. His electrical discoveries secured to him at the comparatively early age of forty-seven an election to the Royal Society of London. Outside of his contributions to electrical science Franklin was the author of many other discoveries of only less importance; among them three are deserving of special mention. They are: (1) The course of storms over the North American continent—a discovery which marked an epoch in the science of meteorology, and which has since been utilised by the aid of land and ocean telegraphy. (2) The course and most important characteristics of the Gulf Stream, its high temperature, and the consequent uses of the thermometer in navigation. (3) The diverse powers of different colours to absorb solar heat.

But the researches upon which Franklin's scientific celebrity mainly depends occupied at the most only seven or eight years, and then gave way to the more immediately pressing calls of his country in other spheres, where only the true proportions of his genius were revealed. His electrical experiments, brilliant as they were, were only the embellishments of his greater career as a statesman and diplomatist. In 1757 he was sent to England to insist upon the right of the province to tax the proprietors of the land still held under the Penn charter for their share of the cost of defending it from hostile Frenchmen and Indians. His mission was crowned with success. He was absent on this work five years, during which he received honorary degrees from Oxford and Edinburgh. In 1764 he was again sent to England to contest the pretensions of parliament to tax the American colonies without representation. The differences, however, between the mother-government and the colonies in regard to the prerogatives of the crown and the powers of parliament at last became too grave to be recon-

ciled by negotiation. The officers sent by the home government to New England were resisted in the discharge of their duty, and in 1775 patriotism as well as regard for his personal safety decided Franklin to return to the United States, where he at once participated actively in the measures and deliberations of the colonists, which resulted in the declaration of their independence on the 4th July 1776, and in constituting what has since been known as the Republic of the United States.

To secure foreign assistance in prosecuting the war in which the colonies were already engaged with Great Britain, Franklin, now in the seventy-first year of his age, was sent to Paris. He reached the French capital in the winter of 1776-77, where his fame as a natural philosopher as well as a statesman had preceded him. His great skill as a negotiator and immense personal popularity, reinforced by the then hereditary antipathy of the French and English people for each other, conspired to favour the purpose of Franklin's mission. A treaty of alliance with the United States was signed by the French king on the 6th of February 1778, while opportune and substantial aids in arms and munitions of war as well as money were supplied from the royal arsenals and treasury. On the 3d of September 1783 his mission was crowned with success through England's recognition of the independence of the United States. Franklin continued to discharge the duties of minister-plenipotentiary in Paris until 1785, when, in consequence of his advanced age and increasing infirmities, he was relieved at his own request. He reached Philadelphia on the 14th of September 1785, when he was elected almost immediately president of the state of Pennsylvania, with but one dissenting vote besides his own. To this office he was twice re-elected unanimously. During the period of his service as president he was also chosen a delegate to the convention which framed the constitution of the United States. With the expiration of his third term as president in 1788 Franklin retired from public life, after an almost continuous service of more than forty years, with a fortune neither too large nor too small for his fame or his comfort. Franklin was the founder and first president of the Philosophical Society of Pennsylvania, and an honorary member of all the leading scientific societies of the Old World.

He died on the 17th April 1790, in the eighty-fourth year of his age, and was buried in the graveyard of Christ Church, Philadelphia. His writings continue to this day to be republished in almost every written tongue, and yet curiously enough he wrote nothing for the press after the termination of his editorial career except a half-dozen or more comparatively brief contributions to the journals of the day, for the rectification of public opinion in Europe on American affairs.

His complete writings, which have been edited by John Bigelow (10 vols. New York, 1886-87) and by Professor A. H. Smyth (with a Life, 10 vols. 1907), consist almost exclusively of letters addressed to private individuals, very few of which were given to the press in his lifetime. Even his scientific discoveries were communicated to the world in letters to personal friends. The very interesting autobiography was specially edited by Bigelow (1868). In the *Life of Franklin* by Bigelow, the author says he had 'tried to condense everything Franklin left behind him that any one not pursuing special investigations now cares to read of the most eminent journalist, philosopher, diplomatist, and statesman of his time.'

Franklin, Sir John, rear-admiral, Arctic explorer, and colonial governor, was born at Spilsby, Lincolnshire, 16th April 1786, the youngest son of a family of twelve children. Franklin acquired the rudiments of learning at St Ives, and attended

Louth grammar-school for two years. His father, in business in Spilsby, had destined John for the church. Such, however, was his enthusiasm for the sea that he determined to be a sailor. A trial voyage to Lisbon only confirming him in this determination, he was in 1800 appointed to the quarter-deck of the *Polyphemus*, and had the following year the honour of serving in the hard-fought battle of Copenhagen. Two months after this engagement Franklin joined the *Investigator*, commanded by his relative Captain Flinders, and under this able scientific officer, who was commissioned to explore and map the coasts of Australia, acquired the skill in surveying so eminently serviceable to him in his future career. Wrecked in the *Porpoise*, August 18, 1803, off the coast of Australia, he made his passage from Canton to England in the *Earl Camden*, commanded by Sir Nathaniel Dance, and acted as signal midshipman in the action, on 15th February 1804, in which Captain Dance repulsed a strong French squadron led by Admiral Linois. A similar post he occupied with equal intrepidity on the *Bellerophon* in the battle of Trafalgar. Lieutenant, and latterly first-lieutenant, in the *Bedford*, Franklin distinguished himself in the attack on New Orleans by capturing one of the enemy's gunboats, receiving a slight wound in the hand-to-hand combat.

The project for the discovery of a north-west passage revived at this period in the nation, and Franklin was appointed to the *Trent*, as second to Captain Buchan of the *Dorothea*, in the expedition of 1818 sent by way of Spitzbergen. Though unsuccessful in its purpose, this voyage yet served to bring conspicuously before the leading scientific men of London Franklin's eminent qualifications for the command of such enterprises, his excellent seamanship, resourcefulness, disinterested love of science, perfect truthfulness and liberal candour in the recognition of the merits of his subordinates, his buoyant cheerfulness of temper, sustained by a deep sense of religion, and calm courage in danger. He was accordingly in 1819 entrusted with the command of an Arctic expedition proceeding from York Factory through Rupert's Land. Wintering the first year on the Saskatchewan, and in the next on the 'barren grounds,' the expedition in the following summer descended the Coppermine River and surveyed a considerable stretch of coast to the eastward, returning in 1822 to York Factory after having traversed 5550 miles by land and water. On his arrival the same year in England, Franklin was raised to the post-rank of captain, and elected a Fellow of the Royal Society. The succeeding year, 1823, he married Eleanor, youngest daughter of Mr Porden, a distinguished architect. In a second expedition, 1825-27, Franklin descended the Mackenzie River, and traced the coast thence through 37° to near the 150th meridian, approaching within 160 miles of the most eastern point attained by Captain Beechey co-operating from Behring Strait. In recognition of his achievements Franklin was knighted in 1829, and awarded the gold medal of the Geographical Society of Paris. His first wife having died in 1825, in 1828 he married his second wife Jane, second daughter of Mr John Griffin.

Appointed to the command of the *Rainbow* in the Mediterranean, Franklin rendered such important service in the 'war of liberation' as to receive from King Otho the Cross of the Redeemer of Greece, and on his return to England was created Knight Commander of the Guelphic order of Hanover. As lieutenant-governor of Van Diemen's Land (now Tasmania), 1834-43, he laboured strenuously to promote the social as well as the political well-being of the colony.

In 1845 Sir John was appointed to the command

of an expedition for the discovery of the North-west Passage. The expedition, consisting of the *Erebus* and *Terror*, with 134 chosen officers and men, sailed from Greenhithe on 19th May 1845, and was last seen on the 26th July following by a whaler in Baffin Bay, in 74° 48' N. lat. and 66° 13' W. long. Franklin's instructions directed him, after approaching the longitude of about 98° W., to make southwards for the coast, along which, basing his conclusions on previous surveys, he felt assured a passage could be navigated from the Fish River to Behring Strait. No tidings of the expedition having reached England, as many as fifteen expeditions were despatched between 1848 and 1854 by England and America, with the object of rescuing or at least finding traces of the missing explorers—a mission in which Lady Franklin bore a noble part. Traces of the missing ships were discovered by Ommanney and Penny in August 1850, and brought home by the *Prince Albert*, which had been fitted out by Lady Franklin. The first winter, as late at least as April 1846, had, it was ascertained, been spent by Franklin and his company behind Beechey Island. In 1854 Dr Rae, conducting an exploring party of the Hudson Bay Company from Repulse Bay, was told by the Eskimos that in 1850 about forty white men had been seen dragging a boat over the ice near the north shore of King William Island, and that later in the same season their bodies were found a little to the north-west of Back's Great Fish River, where they had perished of cold and famine. The latter statement was afterwards disproved, but articles obtained by the Eskimos from Franklin's party and brought home by Dr Rae indisputably proved that the Eskimos had communicated with members of the missing expedition. Following up the direction of Dr Rae's information, the government in 1855 sent two canoes down the Great Fish River. The results of this expedition, added to the examinations which had been made by the many other expeditions of all straits, inlets, and coasts, except the region to the north of the Great Fish River, showed that a party from the *Erebus* and *Terror* endeavouring to reach the Hudson Bay Company settlements had been arrested within the channel into which the Great Fish River discharges. The next exploring party in the yacht *Fox*, purchased and fitted out by Lady Franklin, Captain (afterwards Sir) Leopold M'Clintock, sailed from Aberdeen in July 1857. From the Eskimos in Boothia many relics of Franklin's expedition were gathered by the *Fox*, while articles belonging to Franklin's ships and skeletons found along the west and south coasts told a terrible tale of disaster. Above all, a record found in a cairn at Point Victory told the history of the expedition down to April 25, 1848. This record attested how Franklin on attempting to reach the coast of America was arrested by the obstruction of heavy ice pressing down from Melville Island through M'Clintock Channel (then unknown) upon King William Island.

An addendum in the handwriting of Captain Fitzjames, dated 25th April 1848, briefly narrated that the *Erebus* and *Terror* were deserted 22d April, 5 leagues NNW. of this, having been beset since 12th September 1846; that the officers and crews, 105 souls, under Captain Crozier, landed here in 69° 37' 42" N. lat., 98° 41' W. long.; and that Sir J. Franklin died 11th June 1847. Although many relics of the ships were found in the possession of the Eskimos there is no reason to believe that the retreating crews met with foul play. The American Captain Hall's five years' sojourn among the Eskimos, during which he collected a variety of relics, only confirmed the conclusions reached by M'Clintock. In 1878-80 the expedition of Lieuten-

ant Schwatka of the United States army found the skeletons and other relics of Franklin's men; the bones of one of Franklin's lieutenants (Irving) were brought to Edinburgh and buried. Such is all that is known of the fate of Franklin and his brave men. He is entitled to the honour of being the first discoverer of the North-west Passage. The point reached by his ships brought him to within a few miles of that attained from the westward by previous explorations. A monument erected in 1875 in Westminster Abbey commemorates his heroic exploits and fate. Lady Franklin, whose devotion to her husband and his work has been referred to, died on 18th July 1875 at the age of eighty-three years.

See the article POLAR EXPLORATION and the map there; also the narratives of the expeditions above referred to, especially M'Clintock's *Narrative of the Fate of Sir John Franklin* (1860); the Report of the committee appointed by the Lords Commissioners of the Admiralty (1852), with additional papers (1852), and papers relative to the recent Arctic expeditions in search of Sir John Franklin (1854); Brown, *The North-west Passage* (1858); comparatively brief monographs by Beesly (1880) and Markham (1891); and the Life by H. D. Traill (1896). Sir John's own works were a *Narrative of a Journey to the Shores of the Polar Sea in 1819-22* (1823), and a *Narrative of a Second Expedition in 1825, 1826, and 1827* (1828).

Franklinite, a mineral composed chiefly of peroxide of iron, with oxides of zinc and of manganese, found in considerable quantity in Suffolk county, New Jersey, near the village of Franklin, where it is smelted into iron.

Frankmarriage (*liberum maritagium*) was a species of estate tail, where a man, on the marriage of his daughter or cousin or near blood-relation, gave lands to be held of the donor for four generations by the donees and heirs of their bodies.

Frank-pledge, a custom prevailing in England before the Norman Conquest, whereby the freemen of a neighbourhood were responsible for the good-conduct of each other. Ten men formed an association called a *tithing*, in which the ten were answerable each for the others, so that, if one committed an offence, the other nine were liable for his appearance to make reparation. Should the offender abscond, the tithing, if unable to clear themselves from participation in the crime, were compelled to make good the penalty. The custom seems to have arisen out of the old family obligations, a man's relations being called upon to become securities for payment of the compensation and other fines to which he was liable. A law of Edgar compels every man to find a surety who shall be responsible for his appearance when judicially summoned; and the laws of Canute insist on every one belonging to some hundred and tithing, as well as on his providing sureties.

The *View of Pledge*, or ascertaining to what tithing a man belonged, was an important part of the business of the local courts, and ultimately fell to the *Court leet* or *Court of Frank Pledge*, a court of record held once in the year, and not oftener, within a particular hundred, lordship, or manor, before the steward of the leet: being the king's court granted by charter to the lords of those hundreds or manors. See MANOR.

Franks, the name applied about the middle of the 3d century to a confederation of Germanic tribes dwelling on the Middle and Lower Rhine. The most important of these were the Sigambri, Chamavi, Bructerii, Ampsivarii, Chatti, Attuarii, and Salii. Later they became divided into two principal groups—the Salians, inhabiting the districts on both sides of the Lower Rhine, and the Ripuarians, settled on the Middle Rhine. In the 3d and 4th centuries hordes of them began to move

southwards and westwards into Gaul. In 358 the Emperor Julian, although he defeated the Salian invaders, allowed them to establish themselves permanently in Toxandria, the country between the Meuse and the Scheldt. From this time Frankish chiefs and warriors frequently served in the Roman armies; and during the 5th century they rendered valuable service to the empire in stemming the tide of barbarian invasion, especially at Mainz in 406 and at Châlons in 451. By this time the Salian Franks had made themselves masters of northern Gaul, whilst the Ripuarians were still concentrated around Cologne. Under Hlodowig or Clovis, king (481-511) of the former confederation, the Franks were converted to Christianity, whilst by his conquests in central Gaul, and by his subjugation of the Alemanni and the Ripuarian Franks, he not only extended his dominions as far as the Loire in the one direction and the Main in the other, but he laid the foundations of what subsequently developed into the kingdom of France (q.v.). To the Salian Franks is due the celebrated Salic Law (q.v.), which was probably drawn up before their conversion to Christianity, and to the cognate confederation the *Lex Ripuarianorum*, a code that differed very little from the *Lex Saxonica*. We learn that the Franks were a stalwart race of warriors, distinguished by their free martial bearing, their general aspect of fierceness, their long flowing hair, their blue eyes, and largeness of limb. They constituted a nation of democratic fighting-men, the voice of each individual being of as much weight in the council-hall as his arm was in the thick of battle. In the intervals of peace they tilled the soil, reared cattle, fished, and hunted. They lived together in villages, and had gardens and vineyards. Some amongst them also wrought in gold and iron. The only social grades in their communities were the king, the free Franks, and the slaves taken in war. To the king and his counts belonged the execution of the laws, which were not, however, administered by them, but by specially elected officers in each hundred. The king, although an hereditary ruler, was not an absolute one, his power being controlled in matters of greater moment by the tribal assembly (Marchfeld), when all the men of the tribe met together once a year fully armed. See L. Sergeant, *The Franks* ('Story of the Nations' series, 1898).

Franz, ROBERT, composer, was born at Halle, 28th June 1815, studied under Schneider at Dessau in 1835-37, and in 1843 published his first set of twelve songs, which won the warm praises of Schumann, Mendelssohn, Liszt, and other masters. From then till 1868 he held various appointments at Halle; and when he was compelled to resign them from ill-health, the pecuniary difficulties that ensued were overcome by the exertions of Liszt, Joachim, and others, who in 1872 got up a series of concerts for Franz's benefit, which realised nearly £6000. He published over 250 songs with piano-forte accompaniments, a Kyrie, and several chorales and four-part songs, besides arrangements of the vocal masterpieces of Bach and Handel. Franz's best songs rank with those of Schubert and Schumann. He died 24th October 1892. See *critiques* by Liszt (1872) and Saran (1875).

Franzensbad, or FRANZENBRUNN, a watering-place situated on the north-western frontier of Bohemia, 3 miles NW. of Eger by rail. Lying 1460 feet above sea-level, between spurs of the Erzgebirge and the Fichtelgebirge, Franzensbad has a pure, fresh air and a yearly mean temperature of 45° F. There are a number of mineral springs, besides one which gives off carbonic acid gas and a ferruginous mud spring. The first named, which have a constant temperature of 51° to 54°

F., are of saline and alkaline composition, and are beneficial for diseases of the throat, chest, stomach, liver, for gout and nervous disorders. Pop. 3000, increased by about 5000 visitors during the season. The Czech name is Frantiskovy Lázně.

Franz-Josef. See FRANCIS JOSEPH.

Franz-Josef Land, an archipelago in the Arctic Ocean, north of Nova Zembla, extending, so far as it has yet been explored, between 80° and 83° N. lat. It consists of Graham Bell Land to the north-east, Wilczek Land to the east, Crown Prince Rudolf Land to the north, Alexandria Land to the south-west, and many other islands. Zichy Land, reported by Payer (1874) as separated by Austria Sound from Wilczek Land, turns out to be a group of islands. See map at POLAR EXPLORATION. The southern shores are deeply indented with fjords; and the whole archipelago, which rises into isolated flat-topped or dome-shaped mountains of basalt, is sheeted with ice. Owing to the open water round its shores in summer, and the comparative abundance of its animal life—bears, walrus, foxes, and numerous birds occurring—Franz-Josef Land was long regarded by experienced Arctic explorers as the most favourable base for an attempt to reach the North Pole. The archipelago was discovered and partly explored by Payer and Weyprecht in 1873-74; its southern shores were explored by Leigh Smith in 1880-82, and much of it by Jackson, who met Nansen there (1896), and by later explorers. The Russian flag was hoisted in 1914.

Franzos, KARL EMIL, author, was born in 1848 in Russian Podolia, the son of a Jewish doctor, and passed his earliest years in the Polish-Jewish village of Czortekow in Galicia (the Barrow of his novels). Left an orphan at an early age, he was educated at the German gymnasium at Czernowitz, and studied jurisprudence at Vienna and Glatz, but afterwards settled as a journalist in Vienna. Among his principal works is *Aus Halbusien: Kulturbilder aus Galizien, der Bukowina, Sudrussland und Rumänien* (1876), in which the varied surroundings of his boyhood are gathered into one masterly picture, and which has been translated into most European languages; it is continued in *Vom Don zur Donau* (1878); and *Das Ghetto des Ostens* (1883). His novels include *Junge Liebe*, two tales (1878; 4th ed. 1884); *Die Juden von Barrow* (3d ed. enlarged, 1880; Eng. trans., *The Jews of Barrow*, 1882); *Moschko von Parma* (1880); *Ein Kampf ums Recht* (1881; Eng. trans., *For the Right*, 1887); *Der Präsident* (1884); *Die Reise nach dem Schicksal* (1885); *Tragische Novellen* (1886); *Judith Trachtenberg* (1890; 4th ed. 1893); *Der Gott des alten Doktors* (1892); and *Der Wahrheits-sucher* (1894). Franzos' tales present pictures strong, truthful, and pathetic of life among the Polish and Galician Jews. He died in April 1904.

Frascati, a town of Italy, 15 miles SE. of Rome by rail, stands on the slope of the Alban Hills, near the site of ancient Tusculum. On account of its lovely villas and salubrious air it is a fashionable resort for the people of Rome. The most splendid of these summer residences are the villas Aldobrandini, Rufinella, and Torlonia. Cardinal York was bishop of Frascati, and Prince Charles Edward died here in 1788. Pop. 10,000.

Fraser, ALEXANDER CAMPBELL (1819-1914), born at Ardcath in Argyllshire, studied at the university of Edinburgh, and in 1850-57 was editor of the *North British Review*. At first professor of Logic in the New College, and for a few months a Free Church minister, in 1856-91 he held the chair of Logic and Metaphysics at Edinburgh, and in 1859 became Dean of the Faculty of Arts. His edition of Berkeley's works, with dissertations and

notes, a life of the bishop, and an account of his philosophy, appeared in 1871, *Selections from Berkeley* in 1874, and in 1881 his monograph on *Berkeley* in Blackwood's 'Philosophical Classics,' to which series he also contributed *Locke* (1890). In 1894 he edited Locke's *Essay*, with prolegomena and biography; in 1895-96 delivered the Gifford Lectures on *The Philosophy of Religion*. In 1896 appeared his *Philosophy of Theism* (revised 1899). The article *LOCKE* in the present work is his. See his *Biographia Philosophica* (1904).

Fraser, CLAUD LOVAT (1890-1921), born in London, was educated at the Charterhouse, studied with Mr Walter Sickert and achieved great popularity as a stage and costume designer for the theatre, notably in *The Beggar's Opera*. See a book by Drinkwater and Rutherford (1923).

Fraser, JAMES, D.D., second Bishop of Manchester, was born near Cheltenham in 1818, took a first-class in classics at Oxford in 1839, and in 1840 was elected to a fellowship at Oriel. He was ordained in 1846, and held the livings of Cholderton, Wiltshire, in 1847-60, and Upton Nervet, near Reading, in 1860-70. He was a select preacher before the university of Oxford in 1854-56, and again in 1862-64, and published valuable reports on elementary education in England, on the educational systems of the United States and Canada, and on the employment of children; indeed, it was specifically on the ground of his 'interest in and mastery of the question of public education' that Mr Gladstone in 1870 offered him the bishopric of Manchester. Here his energy, his wide sympathy, and his strong sense secured him a unique position in his vast diocese, and caused his death, on the 22d October 1885, to be deplored as sincerely by dissenters as by churchmen. See *Lives* by Hughes (1887) and Diggle (1889).

Fraser, SIMON. See *LOVAT, LORD*

Fraser, SIR WILLIAM (1816-98), from 1852 an assistant-keeper in the Register House at Edinburgh, was in 1880-92 deputy-keeper of records there. From 1858 he issued a long series of sumptuous Scottish family histories.

Fraserburgh, a fishing town and port in the N.E. of Aberdeenshire, 47 miles N. of Aberdeen by a branch railway (1865). It stands on a bay 2½ miles wide, immediately south of Kinnaid Head (the *Tauacolon Akron* of Ptolemy), on which are the Frasers' old castle, a lighthouse now, and the mysterious 'Wine Tower,' with a cave below. It was founded as Faithlie in 1569 by Alexander Fraser of Philorth, Lord Saltoun's ancestor, and in 1601 was erected into the free port, free burgh of barony, and free regality of Fraserburgh. There are a handsome town-house (1855), a restored market-cross, a public hall, &c.; but hardly a trace remains of an abortive university (1592). The harbour has been much improved and extended since 1855, and the rapid growth of the place is due to the great development of the herring-fishery. Pop. 10,000, doubled during the fishing season.

Fraser Island (also called Great Sandy Island) projects for 50 miles N.E. from the coast of southern Queensland, enclosing Hervey Bay.

Fraser River, the principal stream of British Columbia, is formed by two branches, the chief of which rises in the Rocky Mountains, in 53° 45' N. lat. and 119° W. long., and proceeds in a north-west course to meet its fellow, which flows south-east from Lakes Stuart and Fraser. They unite near Fort George, in 54° N. lat. and 122° 45' W. long.; thence the river flows in a southern direction, and after a total course of 800 miles falls into the Georgian Gulf, just north of the international

boundary of 49° lat. Its chief affluent is the Thompson River. Platinum is got along the Fraser and its tributaries. The rich alluvial deposits of gold along the lower basin of the Fraser first attracted emigration to British Columbia, and the precious metal has since been steadily worked; but the lower valley now enjoys a more secure reputation, as containing some of the best farming land in the province. The salmon canneries are also important. Steamboats can navigate the river for about 100 miles from its mouth to Yale, where the rapids occurring during the passage through the Cascade Range, with its magnificent scenery, begin. See *COLUMBIA (BRITISH)*.

Fraticelli ('little brethren'), a sect of the middle ages which may be regarded as an embodiment, outside of the mediæval church, of the same spirit to which is due, within the church, the Franciscan order with its many offshoots. The Italian word *Fraticelli* originally was the popular name of the Franciscan monks; but, in the progress of the disputes that arose in the order (see *FRANCISCANS*), the name was specially attached to the members of the rigorist party, and eventually to those among them who pertinaciously refused to accept the pontifical explanations of the monastic rule, and in the end threw off all subjection to the authority of the church. Several of the popes, especially Gregory IX. and Nicholas III., attempted to reconcile the disputants. Pope Celestine V. granted permission to the rigorists to form for themselves a separate organisation, in which the rule of St Francis might be observed in all its primitive and literal rigour. The suppression of this order by Boniface VIII. appears to have furnished the direct occasion for the secession of the extreme party from the church. They openly resisted the authority of the pope, whom they proclaimed an apostate from the faith. The party thus formed was increased by adhesions from other sectarian bodies, as the 'Beghards' and the 'Brethren of the Free Spirit.' In vain Clement V., in the Council of Vienna (1311-12), put forward a new declaration regarding the rule of St Francis. They still held their ground, especially in Sicily, central and northern Italy, and Provence. John XXII., against whom they sided actively with Louis of Bavaria, condemned them by a special bull in 1317, and again in a similar document directed against Henry of Ceva, one of their chief leaders in Sicily. From these sources we learn that they regarded the existing church as in a state of apostasy, and claimed for their own community the exclusive title of the Church of God. They forbade oaths, and discountenanced marriage. They professed a divine mission for the restoration of the gospel truth. They held that all spiritual authority was forfeited by sin on the part of the minister. It would even appear that they proceeded so far as to elect for themselves a pope, with a college of cardinals, and a regular hierarchy. Their principles, in a word, seem to have partaken largely of the same fanatical and anti-social tendencies as characterised the Brethren of the Free Spirit; and in common with them the Fraticelli were the object of a rigorous persecution about the middle of the 14th century. The principles of the sect formed the subject of a public discussion at Perugia in 1374 between them and a Franciscan monk named Paolucci, which appears to have ended in their discomfiture. They still maintained themselves, nevertheless, in central Italy, down to the 15th century, when John of Capistrano received a commission to labour for their conversion in the March of Ancona; but before the beginning of the following century they seem to have disappeared altogether. See Mosheim, *De Beghards et Beguinabus* (Leip. 1790); Mil-

man's *Latin Christianity*, vol. v.; Herzog's *Real-encyklopadie*; Lea's *History of the Inquisition* (1888), and the *Catholic Encyclopedia* (1910).

Fratta-Maggiore, a town of Italy, 9 miles by rail N. of Naples, with many villas belonging to Neapolitans. It has extensive rope-works, and cultivates wine and hemp. Silkworms are reared in great quantities. Pop. 13,000.

Fraud, in the legal sense, may be defined as deceit which causes injury to another. Active misrepresentation usually amounts to fraud; but a certain latitude is tacitly permitted to persons puffing their own goods, or exaggerating their own resources and credit. Concealment of the truth amounts to fraud if the party who withholds information is under a legal duty to disclose what he knows. A person purchasing an estate is not bound in law to inform the owner of its advantages; he may have discovered a mine of which the owner knows nothing, but he may conceal his discovery without being guilty of fraud. There are certain cases in which the rules are applied with special rigour. The party deceiving may be in a fiduciary position. A solicitor dealing with his client; a director dealing with a person applying for shares; a man of business dealing with a person who trusts to him and can make no inquiries—all these are plainly under a special duty to state the facts fairly. The party deceived may be incapable of protecting himself;—e.g. transactions with infants or with persons of weak mind must be strictly scrutinised. Again, the transaction itself may be one *uberrimæ fidei*, in which the law requires perfect good faith. A person insuring a ship, for example, is bound to tell whatever he knows of the condition and situation of the ship. It is to be observed that fraudulent intention is not a necessary element in fraud. A prospectus which omits to notice a contract entered into by promoters of a company is none the less fraudulent because the omission is accidental. A gift of property may be set aside as a fraud on creditors, although the donor made it in the full belief that he was perfectly solvent. The general effect of fraud is to render void the contract or disposition of property induced by it, or to give the party injured a right of action for damages or restitution. Even marriage may be treated as a nullity on this ground, if the fraud be such as to exclude the notion of true consent. The principles set forth above are, in substance, common to the laws of all civilised nations.

Fraud is an element in theft, embezzlement, personation, and many other crimes. The offence of obtaining goods or money by false pretences was not indictable by the English common law; it was made punishable by acts passed in 1542 and 1757, the provisions of which were consolidated and amended by the 24 and 25 Vict. chap. 96, which prescribes five years' penal servitude as the maximum punishment. Every person who fraudulently represents as an existing fact that which is not a fact, and so obtains money or money's worth, commits an offence within the act. The false pretence must relate to some present fact, and therefore a promise merely to do some act is not such a false representation as will sustain a conviction. It is not necessary that the deception should be by words or writing, but any act tending to deceive will bring a person within the statute. Thus, a man at Oxford wearing a cap and gown, in order to induce a tradesman of whom he ordered goods to believe that he was a member of the university, was properly convicted. The deception practised, however, must not be simply as to the *quality* of an article, for this is regarded as merely a dishonest trick of trade, and not

criminally punishable. It is also necessary that the owner should be deceived by the pretence; and where a tradesman is induced to part with goods to a regular customer making a false statement, not on account of the statement, but from his belief in the credit of the party, the transaction is not punishable under the act. It is no bar to a conviction that the crime on being proved amounts to larceny, nor is it necessary to prove an intent to defraud any particular person; the obtaining delivery of money, &c. to another person for the benefit of the party using the deception, and also the obtaining signature to, or destruction of, a valuable security, &c. by a false representation subject the offender to punishment. The same statute provides that a person attempting to extort money by threatening to accuse another of certain felonies, or of an infamous crime, is liable to penal servitude for life (see **THREAT**).—*Long Firm* is the name given to a company of swindlers who pretend to be established in business at a particular place, order goods to be sent to them as such, and decamp without payment to resume the system elsewhere. The *Statute of Frauds*, frequently referred to, was passed in 1677.

In Scotland this offence is known as Falsehood, Fraud, and Wilful Imposition. Each species of the offence which in England is punishable under the statute is in Scotland indictable at common law. Thus, false personation, as where a man in the assumed character of an exciseman received money as a composition for smuggled goods, has been held to warrant a conviction of falsehood. So, also, where the deception consists in fictitious appearances; as where a man by fitting his shop with false bales induced another to trust him with goods. Obtaining money by begging-letters and the common practice of ring-dropping fall under this denomination of crime.

In the United States, to constitute the offence known as False Pretences, it is not necessary that the loss occasioned be of a public nature. It consists of a false representation as to some fact existing in the past or present, made with the intent to defraud, by which representation a party is induced to part with something of value to him, generally money, goods, or merchandise. The offence may be committed by a false representation of the nature, quality, or quantity of the goods, or by a false personation, or a false representation of the capacity in which one assumes to transact business; also by the use of false marks or brands, or fictitious or worthless writings, or the false reading of a deed of conveyance to an illiterate person, or by a warranty consisting of a positive false statement of a material latent fact by which a party is induced to purchase. It differs from larceny in that the property is obtained with the consent of the owner, and the false pretence must be the operative cause of the transfer. It is usually a misdemeanour, but the grade of the offence, as also the punishment therefor, is governed by statutes of the several different states. It is recognised as an offence by act of congress, known as the Bankrupt Act (*Rev. Stat. 3732*), but congress has no power to define what shall constitute the offence within a state. The money or goods obtained on false pretence may also be recovered by civil action.

Fraudulent Enlistment. See **DESERTION**.

Fraunhofer, JOSEPH VON, German optician, was born at Straubing, in Bavaria, 6th March 1787. In 1799 he was apprenticed to a glass-cutter and polisher in Munich, and in 1807 he was employed to found an optical institute at Benediktbeuern, of which he became sole manager in 1818, and which a year later was removed to Munich. There he became a member of the Academy of Sciences in 1823, and

was also appointed professor and conservator of the physical cabinet of the same institution. He died 7th June 1826. His more important inventions and improvements in optical instruments include a machine for polishing parabolic surfaces, another for polishing lenses and mirrors without altering their curvature, a spherometer, a heliometer, a micrometer, an achromatic microscope, and the great parallactic telescope at Doipat. But his name has been rendered most celebrated by the improvements he effected in the quality of telescopic prisms and in the mechanism for manipulating telescopes of large size, and above all by his discovery of the dark lines in the sun's spectrum (see SPECTRUM), which bear the name of Fraunhofer's lines.

Fraustadt (Polish *Wozowa*), a town of Prussia, 14 miles NE. of Glogau by rail. It has a tannery, dye-works, a cigar and a sugar factory; here in 1706 the Saxons were routed by Charles XII. of Sweden. Pop. 8000.

Frazer, SIR JAMES GEORGE, folklorist, born in Glasgow in 1854, graduated at Cambridge in 1878 and became a fellow of Trinity. His *Totemism and Exogamy* (1910) developed out of *Totemism* (1887); and *The Golden Bough* (2 vols. 1890; 3d ed. rewritten, 12 vols. 1911-15; abridged 1922) absorbed many of his separately published studies of early superstition, religion, and society. In 1898 he issued a masterly translation of Pausanias; in 1918 *Folklore in the Old Testament*. Professor of Social Anthropology at Liverpool since 1907, he was knighted in 1914. A folklorist of the 'anthropological' school, he amassed a vast body of information relating to the killing of divine kings (see NEMI), vegetation spirits, &c.

Fréchette, LOUIS HONORÉ (1839-1908), 'Canadian poet-laureate,' was born at Lévis, Quebec, called to the bar in 1864, and, after five years' residence in Chicago, elected to the Dominion parliament in 1874. He edited several journals, and published some prose works, plays, and translations into French; but his important productions are his poems, two volumes of which were crowned by the French Academy in 1880. Others are *Mes Loisirs* (1863), *La Voix d'un Enfant* (1869), *Pélemêle* (1877), *Les Oubliés* (1886), and *Voix d'Outremer* (1886), which proved him the most sympathetic of the interpreters of Canadian scenery and of French-Canadian traditions and aspirations.

Freckles (sometimes called *lentigo*) are small yellowish or brownish-yellow irregularly rounded spots, from the size of a pin's head to that of a split pea, frequently seen on the skin, especially of fair or reddish-haired persons. They are not often met with under the age of six or eight. They are most common on the face, but often occur on the hands and sometimes elsewhere. They are always most distinct in summer; but, though the influence of the sun's rays undoubtedly increases their distinctness, it is doubtful whether it can cause them. They are due to increased local deposit of pigment in the skin: and it may be noticed that persons subject to them do not bronze generally under the influence of exposure nearly so deeply as others. Many methods of treatment have been advocated for their removal; but in most cases at least the improvement is not permanent. Among the milder measures which sometimes succeed in improving the condition, is a lotion of hyposulphite of soda (15 to 30 grains) or of chloride of ammonium (15 grains), along with corrosive sublimate ($\frac{1}{2}$ grain to the ounce of water) applied to the part on rag or lint, and they are lessened in intensity by wearing a brown veil in summer.

Fredegon, first mistress, afterwards wife of Chilperic, king of Neustria, a woman of violent and

unscrupulous character, who shunned not to slay all who stood in her way, in order to secure the throne for her own son, Clotaire II. She is, however, chiefly memorable on account of the relentless feud she waged with Brunhilda, wife of Sigbert, king of Austrasia, and sister of Chilperic of Neustria's first wife, Galsvintha; a feud whose bitter enmities were intensified by the rivalry between the two kingdoms. She died in 597 or 598.

Fredericia, a seaport and fortress of Denmark, on the east coast of Jutland, at the northern entrance to the Little Belt. Founded by Frederick III. in 1652, it was five years later stormed and razed by the Swedes, nor was it refortified until 1709. It suffered during the wars of 1848-49 and 1864. Pop. 17,000.

Frederick, a well-built city of Maryland, 61 miles W. by N. of Baltimore by rail, with several foundries, tanneries, flour-mills, and other manufacturing. It contains a college (1797), a Jesuit establishment, and a state institution for the deaf and dumb. Pop. 11,000.

Frederick I., surnamed BARBAROSSA (Red-beard), Holy Roman emperor, of the Swabian family of Hohenstaufen, was born about 1123. He succeeded his father, Duke Frederick II. of Swabia, in 1147, and his uncle, Conrad III., as emperor in 1152. His reign was one long struggle against refractory but powerful vassals at home, and against the turbulent civic republics of Lombardy and the pope (Alexander III.) in Italy. By the capture in 1162 of Milan, the most hostile of the Italian cities, Frederick brought to his feet all the recalcitrant states of Italy; and even the pope, the last of his enemies, he seemed on the point of subduing five years later when he took Rome by storm. But at this juncture his army was suddenly smitten with a terrible plague, and his forces melted away from him. This was the signal for revolt in Lombardy; and when at length in 1174 Frederick was able to leave Germany with the intention of once more reducing his Italian subjects beneath his iron heel, he incurred a severe defeat at Legnano (1176). Nevertheless it was a defeat that proved to be more valuable to him than his previous successes. For it led him to change his policy of stern repression to one of clemency and concession, whereby he converted the Lombard cities from restless, determined enemies into contented subjects. At the same time, in 1177, he acknowledged Alexander III. as pope, and thus paved the way for the final pacification of 1183. In Germany Frederick endeavoured to curb the power of his greatest vassals by a policy of mingled conciliation and counterpoise: the hostility of the strongest he disarmed by investing them with new fiefs, or by raising their titular dignities, whilst the weaker he sought to keep in check by conferring additional rights upon their rivals, the municipal communities. Thus, he elevated the countship of Austria to the rank of a duchy, created Duke Ladislaus of Bohemia king, and granted Westphalia to the Bishop of Cologne, East Saxony to Bernhard of Anhalt, and Brunswick and Lüneburg to the Guelph princes. Besides this, he quelled the rebellious spirit of Henry the Lion of Bavaria, and asserted his feudal superiority over Poland, Hungary, Denmark, and Burgundy. When at the height of his power, however, he took the cross to go and war against Saladin. Marching by way of Hungary, Servia, Byzantium, and Asia Minor, he defeated the Moslems in two battles, at Philomelium and Iconium, but died suddenly, or was drowned crossing the Kalykadnus river (Gök-su) in Cilicia, June 10, 1190. Frederick, who was of great personal beauty and had winning manners, exhibited a resolute will, degenerating at times into gross cruelty, considerable administrative

skill, martial ardour, and a magnanimous ambition. No ruler of Germany ever won a more lasting place in the affections of his subjects than Frederick Barbarossa, about whose memory the patriotic aspirations of the German people have continued to cling in legend and song down to the present day. One persistent tradition makes him still asleep in the Untersberg near Salzburg or the Kyffhauser in Thuringia, whence he will return to succour Germany in her hour of greatest need. His red beard has already grown through the stone table before which he sits, and from time to time he raises his head to see if the ravens are still wheeling round the mountain, or the hour of awakening has come—the dawn of a new golden age for Germany. See works by Prutz (3 vols. Danzig, 1871–73), Ribbeck (Leip. 1881), and Kallsen (Halle, 1882).

Frederick II., OF GERMANY, grandson of Frederick I. (Barbarossa), and son of the Emperor Henry VI., and of Constance, heiress of Sicily, was born at Jesi, in Ancona, 26th December 1194. In the fourth year of his age his father died, leaving him king of Sicily under the guardianship of his mother, who secured the favour of Pope Innocent III. for her son by acknowledging the pope as her feudal superior and conceding to him important privileges. In his eighteenth year Frederick set out, under the auspices of Innocent, to wrest the imperial crown from Otto IV., whom he succeeded in driving out of the empire with little trouble. On his promising to undertake a crusade, the pope sanctioned his coronation at Aix-la-Chapelle in 1215. Like his grandfather, Frederick was actuated by an ardent desire for the consolidation of the imperial power in Italy at the expense of the pontificate, which he wished to reduce to the rank of a mere archiepiscopal dignity. Having secured the nomination of his son Henry to the rank of king of the Romans, and appointed Archbishop Engelbert of Cologne as his vicerent, he left Germany, and, after having been crowned emperor at Rome in 1220, devoted himself to the task of organising his Italian territories. He founded the university of Naples, gave encouragement to the medical school of Salerno, invited to his court and patronised men of learning, poets, and artists, and commissioned his chancellor, Petrus de Vineia, to draw up a code of laws to suit all classes of his German and Italian subjects. Frederick's schemes for the union of his vast and widely scattered dominions were, however, frustrated by the refractory conduct of the Lombard cities, and still more by the antagonism of the popes Honorius III. and Gregory IX. Frederick's departure to the East was originally fixed for the year 1223, but the necessity of subduing the turbulent Italian nobles and cities, and curbing his Saracen subjects in Sicily, caused a delay of two years, and then a further delay of yet two years more. The pope at length grew so impatient that Frederick was constrained to embark from Italy. Nevertheless he returned a few days later, under the plea of personal sickness; this brought down upon him a bull of excommunication from the vehement Gregory IX. In the following year, however, the emperor at length fulfilled his vow, and fulfilled it in brilliant fashion, by securing from the sultan of Egypt, without striking a single blow, the possession of Jerusalem and the holy places, together with a truce for ten years. Then, after crowning himself king of Jerusalem with his own hand, 18th March 1229, he returned to Italy, where the continental half of his kingdom of Sicily had been overrun, at the instigation of the still irreconcilable pope, by a body of mercenary soldiers. During the remainder of his reign Frederick was engaged in a long and harassing contest with the papal power, the hands of his enemy being gradually strengthened

by the accession of the revolted Lombard cities and of several of the princes and towns of Germany, headed by his own son Henry, and by the treachery of his most trusted and intimate friend, the chancellor Vineia. In 1239 he was again excommunicated for having proclaimed his natural son Enzo king of Sardinia, in defiance of the protest of the pope. Nor did the fury of the struggle abate when, in June 1243, Frederick's friend, Sinibaldi Fiesco, succeeded to the pontificate as Innocent IV. And the clouds of disaster, defeat, and misfortune were gathering thicker and more ominously above Frederick's head, when he died somewhat suddenly at Fiorentino, 13th December 1250.

This emperor is one of the most outstanding figures of the middle ages; and, like nearly all such personalities, his character was a blending of contradictory qualities. Intellectually he was perhaps the most enlightened man of his age, in many respects outrunning it by some centuries, as in his tolerance of the Jews and the Mussulmans, in the admiration of the spirit of free trade shown in his commercial legislation and policy, in his recognition of popular representation by annual parliaments, and in his anticipation of the later humanistic movement; but at the same time he was a persecutor of the heretics of the church, a staunch upholder of absolute sovereignty, and a supporter of the power of the princes against the cities. The strength, energy, and elasticity of his character were sadly marred by very conspicuous strains of licentiousness, cruelty, and perfidy. But, though he lacked the moral greatness of his ancestor, Barbarossa, he deserves unstinted admiration for his encouragement of learning and culture, and his fostering care of the arts and sciences. He himself not only spoke the principal languages of his extensive empire—German, French, Italian, Latin, Greek, Arabic, and Hebrew—but he also was one of the first to write Italian poems, took a great interest in the arts, and was himself a diligent student of natural science. It has been brought as a reproach against him that he unduly neglected his territorial possessions in his native country of Germany, and that in religious matters, notwithstanding his crusade, he was far from being a model son of the church, though he was not, in all probability, the 'atheist' his ecclesiastical enemies made him out to be.

See Giesebrecht's history of the emperors; Freeman's essay; books by Schirmacher (1859–65), Huillard-Bréholles (1852–65), Kingston-Oliphant (1862), Winkelmann (1889), Halbe (1888), Felten (1888), Hampe (1899), Blondel (Par. 1892), and Allshorn (*Stupor Mundi*, Lond. 1912).

Frederick III. or IV., German emperor, and the fifth Duke of Austria of that name, was born at Innsbruck, 21st September 1415, being the son of Duke Ernest, of the Styrian branch of the House of Hapsburg. At the age of twenty he assumed the government of Styria, Carniola, and Carinthia. On the death of the Emperor Albert II. in 1440, Frederick was elected king of the Germans; twelve years later he received the imperial crown at the hands of the pope at Rome, and in 1453 he secured the archducal title to his family. Owing to the indolence and indecision of his character his reign was a period of anarchy, wars raging on all the frontiers of the empire, and internal disorders vexing its peace within. During the course of his long and inglorious reign Frederick lost his hold upon Switzerland; purchased peace from his brother Albert, who ruled in Upper Austria, by the payment of a large sum of money; suffered Sforza to possess himself of Milan, George Podiebrad to seat himself on the throne of Bohemia, and Matthias Corvinus on that of Hungary; surrendered the empire to the pope by the Vienna Concordat of 1448; remained apathetic when the

Turks in 1469 penetrated as far as Carniola, and again in 1475, when they almost reached Salzburg; and finally in 1485 provoked Matthias of Hungary to invade his territories. Nevertheless, by the marriage of his son, Maximilian I., to Mary, daughter of Charles the Bold of Burgundy, he laid the foundation of the subsequent greatness of the Hapsburgs. Frederick died on 19th August 1493. Though he neglected the interests and duties of the imperial crown to indulge in his favourite studies, alchemy, astrology, and botany, he never lost an opportunity of promoting the aggrandisement of his own family. He was temperate, devout, parsimonious, scrupulous about trifles, simple in his habits, mild and phlegmatic in his disposition, and naturally averse to exertion or excitement. From his time the imperial dignity continued almost hereditary in the House of Austria, which has perpetuated the use of his favourite device, A.E.I.O.U.—*Austrie Est Imperare Orbi Universo* ('It is Austria's destiny to rule the entire world'). See Chmel's *Friedrich IV.* (2 vols. Hamburg, 1840-43).

Frederick I., king of Prussia, and third elector of Brandenburg of that name, was born at Königsberg, 11th July 1657, and succeeded to the electorate in 1688. Following out the policy of his father, Frederick-William, the Great Elector, he lent valuable support to William of Orange in his attempt on England. He employed the treasure collected by his father largely in the purchase of minor principalities and territories; and further increased his revenue by lending his soldiers to fight the battles of the neighbouring princes, especially against France. But the outstanding event of his reign was his own elevation to the dignity of king, 18th January 1701, the title being taken from Prussia, the only independent portion of his dominions. Good-natured but vain, generous but ungrateful, Frederick left the finances of his country in an embarrassed condition. Nevertheless, his public spirit led him to found the university of Halle, to embellish Berlin, to found there the Academy of Sciences and the Academy of Painting and Sculpture, and also to establish a supreme court of appeal. Frederick died 25th February 1713, and was succeeded by his son, King Frederick-William I. See works by Hahn (3d ed. Berlin, 1876), Ledebur (Berlin, 1878), and Heyck (1901).

Frederick II., OF PRUSSIA, surnamed 'THE GREAT,' born at Berlin, January 24, 1712, was the son of Frederick-William I., and of Sophia-Dorothea, daughter of George I. of Great Britain. His early years were spent under the restraints of an irksome military training and a narrow and unsympathetic system of education, against which not only the natural restiveness of youth but also the more liberal tastes implanted by his mother rebelled fiercely but vainly. At the age of eighteen the prince made an unsuccessful effort to escape to the court of Great Britain. His father saw in this attempt an act both of political rebellion and of military insubordination, and, influenced perhaps by the desire of saving the glory and acquisitions of his house from one whom he considered an unworthy successor, would have punished Frederick with death, had it not been for the intercession of the emperor. As it was, the prince was ordered into close confinement at Küstrin, while his confidant, Lieutenant Katte, was beheaded before his eyes. Frederick recognised that submission was inevitable. He threw himself with nervous alacrity into the military and civil duties with which he was after a time entrusted, while his letters to his father of this period are couched in almost servile terms. He won his final restoration to favour when in 1733 he dutifully accepted the bride

chosen for him by his father (the Princess Elizabeth-Christina of Brunswick-Wolfenbüttel, 1715-97). From 1734 Frederick resided at Rheinsberg, where he held a kind of small literary court, and devoted his leisure to the study of music and French literature, for which he had a keen and lasting admiration. He corresponded with Voltaire (who afterwards, in 1750, visited Berlin), and studied with much sympathy the 'philosophical' doctrines which were to play so important a part in the century. There is no doubt that he now began to nourish schemes of political ambition. Even before he came to the throne he clearly perceived that, if the House of Hohenzollern was to play an adequate part in European politics, its possessions must be consolidated and extended; before he died the area of Prussia was doubled, and, notwithstanding the temporary eclipse under Napoleon, the foundation of Prussia's greatness was laid. Hostile critics assert that Frederick's prevailing motive was mere selfish dynastic ambition; they point to the fact that all his wars were aggressive, and that in every case he struck the first blow; they reproach him with unpatriotically encouraging the interference of France in the affairs of Germany for his private ends, and they taunt him with his contemptuous neglect of German literature and language, which last he could scarcely speak, and certainly could not spell. But there is no doubt that the terrible struggle of the Seven Years' War left him, if it did not find him, with a true appreciation of the solidarity of his own and his people's interest; he assuredly did not spare himself in their service; and his measures and reforms, harsh and autocratic as many of them now appear, were undertaken with a single eye to the national good. The rise of Prussia under Frederick really rendered possible the union of Germany which his critics accuse him of retarding, but which could never have been effectually carried through under a dominant Austria, haughty with centuries of imperial tradition.

On May 31, 1740, Frederick became king; and in the following October the accession of Maria Theresa separated the crown of Austria from the imperial diadem. Frederick, in possession of an admirably drilled army and a well-filled treasury, seized the opportunity. Reviving an antiquated claim to Silesia, he entered that province (December 1740) before his formal declaration of war reached Vienna, defeated the Austrians at Mollwitz (April 1741) and Chotusitz (May 1742), and, having concluded an alliance for fifteen years with France, forced Maria Theresa to yield him Upper and Lower Silesia by the Treaty of Breslau in June 1742, which closed this first Silesian war. The second Silesian war (August 1744 to December 1745) left Frederick with still further augmented territories, and the reputation of being one of the first military commanders of the day. The next eleven years were years of peace; but Austria was not yet reconciled to the loss of Silesia, and Frederick's energetic internal reforms were coloured by the expectation of renewed war. In 1756 the third Silesian war, better known as the Seven Years' War (q.v.), began. Frederick anticipated attack by himself becoming the aggressor, and during all this momentous struggle—one of the most remarkable of modern times—displayed a courage, a military genius, and a power of resource both in victory and defeat which justly entitle him to the name of 'the Great.' At the Peace of Hubertsburg (February 15, 1763), he had not only maintained his territory undiminished, but he had also added a tenfold prestige to Prussia and to Prussian arms. Jealousy of Austrian aggrandisement continued to influence his policy. In 1772 it induced him to share in that dishonest act, the first partition of Poland, which

added Polish Prussia and a portion of Great Poland to the Prussian crown. In 1778 it led him to take arms in a brief campaign, which ended in the acquisition of the Franconian duchies. And one of his latest political actions was the formation of the 'Fürstenbund,' or League of Princes, which was the first definite appearance of Prussia as a rival to Austria for the lead in Germany. Frederick died at Potsdam, August 17, 1786, and was succeeded by his nephew, Frederick-William II.

Frederick, like Richelieu and like Bismarck, when foreign war ceased turned his immediate attention to the internal affairs of his kingdom. He was an able administrator at all periods of his reign, and not the least remarkable of his feats was his carrying on all his wars without incurring a penny of debt. He regarded himself as, in his own words, the first servant of the state; he was his own prime-minister in a very literal sense, for his cynical suspicions of human motives induced him to interfere directly in things great and small. His conviction of the immaturity of his country explains the discrepancy between his theoretical writings on government and the scant amount of liberty he granted to his people. He considered himself responsible for the good of his people, and he justified his arbitrary actions by his good intentions and his keener insight. As already remarked, Frederick's domestic legislation was influenced by what he believed to be the military requirements of the time; Prussia under him was governed as one huge camp. He endeavoured to increase the population—i.e. the supply of soldiers, by a system of 'planting colonies,' by lending his war-horses to plough the peasants' land, by distributing military stores, and by temporary remission of taxes in certain provinces. But he did not carry the enfranchisement of the peasantry to such an extent as to injure or offend the nobility, whom he required for officers. With a view to providing treasure for future wars he fostered woollen and other manufactures by a high protective tariff; but he made himself unpopular by the introduction of the French excise-system, known as the Regie, and the temporary inflation of his revenue was attended with later disastrous commercial results. During Frederick's reign, however, the country rapidly recovered from the ravages of war, while the army was raised to a strength of 200,000 men. Frederick was essentially a just, if somewhat austere man, and the administration of justice under his rule was pure, though he himself had his usual cynical distrust of his judges' integrity; the press enjoyed comparative freedom; and freedom of conscience was promoted. Though Frederick was himself a voluminous writer on political, historical, and military subjects, he had no sympathy with nascent German literature, a fact on which the latter is perhaps to be congratulated. The spirit of the century went faster than Frederick; had he lived he would not have understood the logical outcome of his *philosophie* doctrines in the French Revolution. His works, written wholly in French, have been published in thirty-one volumes under the auspices of the Berlin Academy (Berlin, 1846-57), which in 1878 also undertook an edition of his *Political Correspondence*.

The chief authorities for the life of Frederick are, besides his own *Œuvres* and *Correspondance*, and the official publications of the Prussian Archives, Preuss's *Friedrich der Grosse* (4 vols. Berlin, 1832-34); Carlyle's *History of Frederick II.* (6 vols. Lond. 1858-65); and Droysen's *Friedrich der Grosse* (2 vols. Leip. 1874-86), being part v. of his *Geschichte der Preussischen Politik*. Numerous monographs upon special epochs in his life or special phases of his character have also been published. The leader of the hostile school of criticism is O. Klopp, in his *Friedrich II. von Preussen und die Deutsche*

Nation (Schaffhausen, 1867). Rigolot, in his *Frédéric II. Philosophe* (Paris, 1875), gives us a French view of the king; as does the Duc de Broglie in his *Frédéric II. et Marie Thérèse* (1883). There is an English translation (1877) of Kugler's *History of Frederick the Great*, with 500 famous and characteristic illustrations by Menzel. See also Brackenbury, *Frederick* (1884); Tuttle, *Prussia under Frederick the Great* (N.Y. 1888); Reddaway, *Frederick the Great and the Rise of Prussia* (1904); N. Young, *Life of Frederick the Great* (1919).

Frederick III., second German emperor and eighth king of Prussia, only son of the Emperor William I., was born at Potsdam, 18th October 1831. In 1858 he married Victoria, the British Princess Royal (1840-1901). On becoming Crown-prince of Prussia in 1861, he protested against Bismarck's reactionary policy in relation to constitutional questions and the press. He went through the Danish war (1864), and in the war with Austria (1866) commanded the second Prussian army. In the Franco-German war 'our Fritz' commanded the third army; he had a share in the glory of Wissembourg, Worth, and Sedan, and was made field-marshal (1870). In 1871 he became Crown-prince of the German empire. In 1878, when the Emperor William was wounded by an assassin, the Crown-prince was appointed provisional regent. In 1887 he began to suffer from an affection of the throat, which in a few months assumed a malignant form; on 9th February 1888 the operation of tracheotomy was performed. On 9th March the Emperor William died; and the Crown-prince, returning from San Remo to Prussia, was proclaimed emperor as Frederick III., but he died at Potsdam, 15th June 1888. His son, William II., succeeded him. Frederick had a great horror of war, intensely disliked autocratic ideas, and sought to liberalise German institutions. See his *Tagebuch* (ed. Engel, 1919), *English Life* by Rennell Rodd (1888); and German ones by Müller, Ziemssen, Bohn, Freytag (1889), and Philippson (1900).

Frederick V., ELECTORAL PRINCE PALATINE, son of Frederick IV., was born at Amberg, 26th August 1596, and succeeded to the Palatinate in 1610. He married, in 1613, Elizabeth (q.v.), the daughter of James I. of England, through whose ambitious counsels he was induced to put himself at the head of the Protestant union of Germany, and finally, although against his own inclinations, to accept the crown of Bohemia in 1619. His complete defeat at the battle of the Weisse-Berg, near Prague (1620), terminated his short-lived reign, in allusion to which he became henceforth known as the 'Winter King.' In the meantime the Palatinate was occupied by the Spaniards and Bavarians. Frederick therefore took refuge in Holland. Declared under the ban of the empire in 1621, he lost his electoral principality two years later, when the emperor conferred it upon Maximilian of Bavaria. Frederick died at Mainz, 29th November 1632. His son got back the Palatinate after the Treaty of Westphalia (1648).

Frederick III., of Denmark, was born in 1609, succeeded to the throne in 1648, and died in 1670. His reign was rendered memorable by the change effected in the constitution (see DENMARK).—FREDERICK V. (1723-66) ascended the throne in 1746, and proved one of the best and wisest monarchs of his time. Denmark owed to him the increase of her national wealth, and the establishment of various branches of commerce and manufacture. He established an Asiatic Company, opened the American colonial trade to all his subjects, encouraged painting and sculpture, and sent a learned commission to travel and make explorations in Egypt and the East.—FREDERICK VI. (1768-1839) assumed the regency of the kingdom in

1784, on account of the insanity of his father, on whose death in 1808 he ascended the throne. In his reign feudal serfdom was abolished, the criminal code amended, and the slave-trade prohibited in the Danish colonies. For his luckless participation in the Napoleonic wars, and for the constitution which he granted in 1831, see DENMARK.—**FREDERICK VII.** (1808–63), who succeeded in 1848, was the last of the Oldenburg line (see DENMARK). The principal events of his reign were the wars and diplomatic negotiations arising out of the revolt of the duchies of Holstein and Sleswick (see SLESWICK-HOLSTEIN).

Frederick, PRINCE OF WALES (1707–51), eldest son of George II., quarrelled with his father over his own marriage. In 1737 he joined the parliamentary opposition, was banished from court in consequence of his ill-treatment of his wife and of his disobedience to his father. He died before his father, leaving his son to ascend the throne as George III. on the death of George II.

Frederick-Charles, a Prussian prince, nicknamed the 'Red Prince' from the colour of his favourite hussar uniform, was born in Berlin, 20th March 1828, the eldest son of Prince Charles, who was a brother of the Emperor William I. Frederick-Charles was educated for the army, and served in the first Sleswick-Holstein war, commanded the right wing in the second Danish war, and in 1866, in the campaign against Austria, won the great victory of Königgrätz. In the Franco-Prussian war he commanded the second army, drove Bazaine back to Metz, and on the 27th October received the capitulation of that fortress (see BAZAINE). He was made a field-marshal next day, captured Orleans, broke up the army of the Loire, and scattered Chanzy's portion of it at Le Mans. This was his last action, for Paris capitulated immediately after. One of the ablest of Prussian generals, he added to his active service successful labours to reform the military system and render it more elastic. He died 15th June 1885.—In March 1879 his third daughter, Louise Margaret, born in 1860, was married to the Duke of Connaught. She died in 1917.

Fredericksburg, a city of Spottsylvania county, Virginia, on the Rappahannock, 56 miles N. of Richmond, with flour-mills and other manufactures. Washington's mother is buried close by. On the hills to the south Burnside (q.v.) attacked and was repulsed by the Confederates in December 1862. Pop. 6000.

Frederick-William, ELECTOR OF BRANDENBURG, commonly called 'the Great Elector,' was born 16th February 1620, at Colln on the Spree, succeeded to the electorate in 1640, and died 9th May 1688. On his accession he found an empty exchequer, the towns and cities depopulated, and the whole electorate disorganised, exhausted, and horribly devastated by the Swedish and Imperialist armies during the Thirty Years' War. His first acts were to regulate the finances and to conclude a treaty of neutrality with Sweden, which left him at leisure to devote himself to the organisation of his army and the repopling of the deserted towns and villages with immigrants. By the Treaty of Westphalia (1648), which he zealously promoted, at the sacrifice of a considerable slice of territory in Western Pomerania, he nevertheless recovered the eastern portion of Pomerania, the principalities of Halberstadt, Minden, and Kammin, and the reversion of the archbishopric of Magdeburg. Then in the course of ten years of peace he laboured hard to raise the condition of Brandenburg; but he also created an army of 25,000 men, organised on the Swedish model. Out of a quarrel between Sweden and Poland he contrived to draw

advantage for himself, in that he secured the independence of the duchy of Prussia from Poland (1657). After another fifteen years of peace the elector, alarmed at the aggressions of Louis XIV. on the Rhenish frontier, induced the emperor, the king of Denmark, and the Elector of Hesse-Cassel to enter into a league against France. Thereupon Louis incited the Swedes to invade Brandenburg, and to advance upon Berlin. Frederick-William, however, signally defeated them at Rathenow and at Fehrbellin (1675), and drove them from his dominions. Nevertheless, being forsaken by the emperor and the other German princes, and being left to face France single-handed, he was obliged to agree to the Treaty of St Germain (1679), by which he restored all his conquests to the Swedes, in return for the withdrawal of the French army from Brandenburg and the payment to him of an indemnity of 300,000 crowns. From this time forth Frederick-William devoted himself to the task of consolidating his dominions, and fostering their agricultural, industrial, and commercial development. He extended a hearty welcome to several thousand French Protestants after the revocation of the Edict of Nantes, and encouraged the immigration of Dutchmen and other foreigners, whereby he introduced numerous industrial arts among his subjects. He founded the university at Duisburg, and the royal library at Berlin, and reorganised the universities of Frankfort-on-the-Oder and Königsberg, opened canals, established a system of posts, and greatly enlarged and beautified Berlin. He left a well-filled exchequer and a highly-organised army. A man of imposing personal appearance, he was of bold and energetic temperament, of a quick temper, a resolute will, and an ambitious mind that looked a long way ahead and laid plans accordingly. Brandenburg he converted from a weak constitutional state into what was virtually an absolute monarchy only less powerful than Austria in the German polity of states. He laid the foundations of the bureaucratic and military aristocracies of the subsequent kingdom of Prussia, and formed the nucleus of a small fleet. Besides this, he encouraged education, and made himself the champion of religious toleration. He was succeeded by his son, Frederick III., afterwards King Frederick I. of Prussia.

Frederick-William I., king of Prussia, born 15th August 1688 at Berlin, was in almost every particular the opposite of his father, Frederick I. In the same year (1713) that he ascended the throne he became embroiled in the war waged by Sweden against Russia, Poland, and Denmark, on behalf of the latter. At the Peace of Stockholm in 1720 Frederick-William received Hither Pomerania with Stettin. But the remaining twenty years of his reign were devoted to the amelioration of the internal condition of Prussia. Of a sternly practical turn of mind, despising the arts and sciences, rigidly economical, strict in his ideas of justice, blunt and determined, this king carried into all departments of his administration the habits and principles of the frugal military martinet. The results of his policy were seen at his death (31st May 1740), when he left to his son, Frederick II., a treasure of nine million thalers and an army of more than 80,000 men, the best drilled and disciplined force in Europe, so that Prussia, though ranking only twelfth among the powers of Europe in respect of population and area, came fourth in military power. He also fostered the industries and agriculture of his dominions, introducing the manufacture of woollen cloth, and settling in East Prussia 17,000 to 18,000 Protestant refugees from Salzburg. On the whole, his rule, arbitrary though it was, laid the foundation upon

which Frederick the Great worked for the subsequent greatness of Prussia.

Frederick-William II., king of Prussia, nephew of Frederick II., was born 25th September 1744. As a young man he failed to win the goodwill of his uncle, owing to his excesses and his disinclination to work. Nevertheless, the natural mildness of his disposition, together with the abolition of some of the oppressive measures of Frederick II.'s reign, made him very popular at his accession in 1786. But he soon lost the affectionate regard of his subjects by his predilection for unworthy favourites, and by the abrogation of the freedom of the press and religion (1788). His uncle left him a treasury containing more than fifty million thalers; these he dissipated in a useless war with Holland. In short, his foreign policy was weak and lacking in character, whilst at home he starved the budding sense of patriotism in his subjects, and oppressed them with debt and increased taxation. He added New East Prussia, South Prussia, New Silesia, Danzig, and Thorn to his kingdom by the partitions of Poland in 1793 and 1795, and also acquired the districts of Ansbach and Baireuth. Frederick-William II. died 16th November 1797, and was succeeded by his son, Frederick-William III.

Frederick-William III., king of Prussia, son of Frederick-William II., was born 3d August 1770, and ascended the throne in 1797. His reign may be divided into three periods. During the first of these his lack of energy and purpose led him to take up an attitude of passive neutrality towards Napoleon; but at length the truculent policy of the latter so exasperated the Prussians that, instigated by their queen, they forced the king to declare war against the French (1806)—a most disastrous step, as, after being thoroughly worsted at Jena and Auerstädt, Frederick-William was compelled to flee into East Prussia, leaving his kingdom to be overrun and his capital captured by Napoleon. Nor was that all: by the Treaty of Tilsit (1807) Prussia was diminished by one-half, being deprived of all her territories west of the Elbe, and all that she had acquired by the partition of Poland. The second period (1806-15) is marked by the administrative reforms of Stein (q.v.) and the war of liberation (see GERMANY). By the Treaty of Vienna (1815), which terminated that war, Prussia recovered her possessions west of the Elbe, and acquired the duchies of Berg and Juliers (Jülich), the northern half of Saxony, and other districts in Westphalia, besides securing the remaining (Swedish) portion of Hither Pomerania; but she gave up her Polish acquisitions, with the exception of Posen, to Russia, the province of Friesland to Holland, and Ansbach and Baireuth to Bavaria. The last period of this reign was generally one of reaction. The king and his minister Hardenberg applied the Metternichian principles of government in Prussia, rigorously suppressing the democratic movements of 1819 and 1830, and strictly curtailing the freedom of the press. Nevertheless, the policy of reform inaugurated by Stein did not remain altogether stationary; provincial diets were established (1823), though allowed merely consultative functions; the finances were put on a better footing; the system of taxation was greatly improved; education was encouraged; and the Zollverein or customs union was established. In private life this king exhibited the virtues of justice, a strong sense of duty, purity, and love of truth; but his public conduct was rendered unsatisfactory by his indecision of character, his great diffidence, narrowness of view, and the limited extent of his knowledge. His wife was the beautiful and noble-minded Louisa (q.v.), idolised by the Prussian people for

her patriotism. He died at Berlin, 7th June 1840, and was succeeded by his son, Frederick-William IV.

Frederick-William IV., king of Prussia, son of Frederick-William III., was born October 15, 1795. His reign is characterised by one long struggle of the people of Prussia against their king for a constitutional form of government. Frederick-William IV. exhibited much of his father's vacillation and instability of purpose; and, although he began his reign (June 7, 1840) by granting minor reforms and promising radical changes of a liberal character, he always evaded the fulfilment of these pledges. He was possessed by high but vague ideas of the divine right of kings, and showed a strong tendency to mystic pietism. A determined enemy to the ideas of the French Revolution, he refused to accept the imperial crown offered him by the Liberal Frankfort Diet in 1849; and at first he resolutely opposed the popular movement which followed the French Revolution of 1848; but when the people emphasised their reiterated demand for constitutional government by storming the arsenal and seizing on the palace of the Prince of Prussia, afterwards the Emperor William I., who was at that time especially obnoxious to the Liberals, the king complied with their wishes. At length, on 31st January 1850, the country was granted a representative parliament, summoned in accordance with the terms of a written constitution, based upon democratic principles. In 1857 Frederick-William was seized with remittent attacks of insanity, and resigned the management of public affairs to his brother and heir, who from 1858 acted as regent of the kingdom till his own accession, as William I., on the death of Frederick-William, 2d January 1861. See his Life by Ranke (1878), and by Petersdorff (1900).

Frederick-William (1771-1815), DUKE OF BRUNSWICK. See BRUNSWICK.

Fredericton, capital of the province of New Brunswick, Canada, stands on the St John River, 58 miles NNW. of the port of St John. It is the seat of an Anglican bishop and of a university, and has some handsome government buildings. There are some manufactures, and a considerable trade in lumber is carried on. Pop. 8000.

Frederikshavn, a port in the north of Jutland, on the Cattegat, 52 miles NE. of Aalborg by rail. It is much used as a harbour of refuge, and has a considerable trade, exporting butter, cattle, and pigs (to England), and importing wood, iron, corn, cotton-yarn, &c. Pop. 12,000.

Frederiksted, a town of St Croix in the Virgin Islands of the United States; pop. 3000.

Fredrikshald, a fortified seaport of Norway, on the Idde Fjord, near the Swedish border, 85 miles by rail SSE. of Christiania. Having been burned down in 1826, it was rebuilt in modern style, with broad and regular streets. Its inhabitants trade in timber. To the south-east of the town stands the fortress of Fredriksteen, built in 1661, which, though often assaulted, has never yet been taken. Charles XII. of Sweden was killed in the trenches before this fortress on 11th December 1718. A little farther to the east stands the fort of Gyldenlove, which has played an important part in the wars between Sweden and Norway. It is now, however, of little consequence. Formerly called Halden, Fredrikshald received its present name from King Frederick III. of Denmark. Pop. 11,000.

Fredrikstad, a seaport town of Norway, at the mouth of the Glommen, 58 miles S. of Christiania by rail, exports timber; pop. 16,000.

Free Bench (*Francus Bancus*). By custom of certain manors of England a widow was entitled

to dower, called 'free bench,' out of the lands which were held by her husband, provided she remained unmarried and chaste.

Free Church of England, an Episcopal church founded in 1844, closely agreeing with the evangelical section of the Church of England, arose in opposition to the Tractarian movement. —In 1890–92 there was formed a federation of the evangelical nonconformist churches of England (Congregationalist, Baptist, Methodist, Presbyterian, Free Episcopal, Society of Friends, and others), holding annually a National Council of the Free Churches.

Free Church of Scotland, the name assumed by those who at the 'Disruption' of the Church of Scotland, in 1843, withdrew from connection with the state, and formed themselves into a distinct religious community, claiming to represent the historic church of Scotland, and to maintain the principles for which it had contended since the Reformation. The Free Church (now, as incorporated with the United Presbyterian Church, part of the United Free Church; see below) retained the standards used by the Established Church; but a catechism, approved by the Free Church Assembly after 1843, makes the right to vary the document of creed, or to exchange it for another (without the sanction of the state), one of the tests of the freedom claimed for the church against the decisions of 1843. Speaking generally, it may be said that the laws of the church existing and in force prior to the Disruption are acknowledged as still binding in the Free as in the Established Church, but only in so far as they have had church authority, and with the exception of those which the Free Church has since repealed. The same Presbyterian constitution subsists in both churches, with the same classes of office-bearers and gradations of church-courts. The Free Church, indeed, professes to maintain this constitution and church-government in a perfection impossible in the present circumstances of the Established Church, because of the supremacy of parliament by which the Established Church is trammelled, and interventions of civil authority to which it is liable. And the whole difference between the Free Church and the Established Church relates to the necessary submission of the Established Church to this control of the civil power in things which the Free Church regards as belonging not to the province of civil government, but to the church of Christ, and to its office-bearers and courts as deriving authority from him; so that the controversy was often described as respecting the *Headship of Christ* or the *Kingdom of Christ*. It is to be borne in mind, however, that the doctrine of the headship of Christ over his church, being set forth in the Westminster standards, is fully professed both by the Established Church and by the Free Church of Scotland; the only question between them is whether or not the existing relations of the Established Church of Scotland to the state are consistent with the due maintenance and practical exhibition of this doctrine. And the question does not directly relate to *Voluntarism* (q.v.). Those who constituted the Free Church of Scotland in 1843 firmly believed that the church might be connected with the state, and receive countenance and support from it, to the advantage of both. But they maintained that there must not, for the sake of any apparent benefits flowing from such connection, be any sacrifice of the independence or self-government of the church, as the kingdom of Christ, deriving its existence, organisation, and laws from him. Even then, too, most of the leaders of the Free Church held, with Dr Candlish and Dr Cunningham, that the separation of 1843 was practically final, and that in the improbable event of the state acknow-

ledging the church's independence the church should hesitate before again forming with it so close and perilous a connection. The leaning thus indicated from that time steadily increased. Many of the second generation of Free Churchmen accepted as practically if not theoretically true the inconsistency repeatedly urged upon their fathers by the law-courts, as existing between the claim of church freedom and all establishment whatever. And in coming to the same conclusion of final separation from establishment they increasingly connected it with the equal rights of conscience of all citizens, and not, as their fathers did, with the claims and confession of the church alone.

The Westminster Confession of Faith asserts that 'there is no other head of the church but the Lord Jesus Christ;' and that 'the Lord Jesus, as King and Head of His church, hath therein appointed a government in the hand of church-officers, distinct from the civil magistrate.' The early Presbyterians of Scotland so far prevailed as to obtain at different times important acts of parliament in recognition of their principles, and 'ratification of the liberty of the true kirk;' and finally, after the Revolution of 1688, an act ratified the Westminster Confession of Faith itself, and incorporated with the statute law of the realm all its statements concerning the province of church-judicatories and that of the civil magistrate, and the bounds of their respective powers. The rights and privileges of the Presbyterian Church of Scotland, guaranteed by the Revolution settlement, were expressly secured by the Treaty of Union, and jealously reserved from the power of the British parliament; yet within five years afterwards, when Jacobite counsels prevailed in the court of Queen Anne, an act was passed for the restoration of patronage in Scotland, with the design of advancing the Jacobite interest by rendering ministers more dependent on the aristocracy. This act soon became the cause of strife within the Church of Scotland, and of separations from it during the 18th century. But when the 'Moderate' party, long dominant in the General Assembly of the Church of Scotland, became again the minority in 1834, the accession of the 'Evangelical' party to power was at once signalised by an attempt to restore to the congregation its influence in the election of their pastor. This was done by the *Veto Law*, by which it was declared that 'it is a fundamental law of this church that no pastor shall be intruded on any congregation contrary to the will of the people.' And the same General Assembly by which the Veto Act was passed asserted the constitutional principles and inherent powers of the church in another important particular, the admission of the ministers of 'chapels of ease' to the same ecclesiastical status as the ministers of endowed parishes, in consequence of which they became members of church-courts, and had districts assigned to them *quoad sacra*, with the full parochial organisation.

These acts were soon the subject of litigation in the Court of Session. A conflict arose which in various forms agitated the whole of Scotland, and which, ere long, related as much to the status of chapel ministers (and of ministers whom the church had of its own authority gladly welcomed back from the seceding bodies outside) as to the mere rights of presentees. It involved, indeed, the whole question of the relations of civil and ecclesiastical powers, at least as far as the Established Church was concerned. There was scarcely a spiritual or ecclesiastical act falling within the region thus dealt with by the church which the court did not now 'interdict' and prohibit; while other spiritual acts, such as admission to the ministry, it ordered the church to perform under penalties. But a graver matter still was the principle upon which

these orders were uniformly based. The court not merely disallowed the claim of the church to freedom and legislative self-expansion; it founded its long series of judgments, beginning with the Auchterarder case, on the absolute subjection of the church to parliament, and on the authority of statute even in matters ecclesiastical. The heads of the Court of Session and House of Lords announced the law that 'parliament is the temporal head of the church, from which it derives all its powers;' that 'the law, and that alone, gave the church jurisdiction;' that therefore it is impossible to admit, not only 'that an establishment can ever possess an independent jurisdiction,' but even that there can be such a thing as 'a conflict between the civil and ecclesiastical courts of a country in which a church is established and endowed by the state.' And as to the plea that the rights of congregations were guarded on the religious side by a 'fundamental law' of the church, the House of Lords laid it down that 'whether that is, or ever was, a law of the Church of Scotland, is perfectly immaterial, if the statutes contain enactments and confer rights inconsistent with it.' These principles, common enough in the jurisprudence of some countries, appeared violently hostile to the old doctrine of the Church of Scotland. But the one thing in which that church now agreed with the court was that its carrying out the orders of the latter in the church sphere would involve acquiescence in the principles of establishment authoritatively laid down. Accordingly, the General Assembly formally refused, and in 1842, by a majority of 241 to 110, passed a *Claim of Right*, declaring to parliament and the crown that the church, unless relief were granted, must separate from the state. In November of the same year a *Convocation* was held to arrange for the future. In parliament Mr Fox Maule's motion for inquiry, made on 7th March 1843, was supported by a large majority of the Scottish members, but rejected by Sir Robert Peel and the house. The crisis came on 18th May 1843, when the General Assembly should have constituted itself in Edinburgh. Instead of doing so, the ex-Moderator, Dr Welsh, handed a protest to the Queen's commissioner, and he and the others who had signed it, issuing from St Andrew's Church, moved in a long procession down the northern slope of Edinburgh to Canonmills. There 474 ministers (out of a total of 1203) resigned their churches, incomes, and homes; and amid a scene of great emotion Dr Chalmers was called to the chair of the first Assembly of the Free Church of Scotland.

The event produced an impression throughout Christendom. 'To the moral attitude of the Free Church,' said Mr Gladstone to the House of Commons a quarter of a century later, 'scarcely any word weaker or lower than that of majesty is, according to the spirit of historical criticism, justly applicable.' The sacrifices and sufferings which not only its ministers but its congregations were called on to undergo, especially in districts where land-owners for years refused sites for buildings, were no doubt the first cause of this. But something must be allowed to the extraordinary qualities of the Scotsmen who became the leaders and founders of the new body. Dr Chalmers, the greatest of them all; Dr Candlish, for thirty years his brilliant successor; Dr William Cunningham, the controversialist and theologian of the body; Dr Robert Buchanan, its administrator and (in his *Ten Years' Conflict*) its historian; Dr Guthrie, its orator; Mr Murray Dunlop, its lawyer; Hugh Miller, its *littérateur*; these men and some others, as they are sketched in their own utterances and in books like Lord Cockburn's *Journal*, take no common rank even as individuals. And they formed a group so impressive, intellectually and morally, that even the

Duke of Argyll, who declined as a young man to follow the Free Church, when looking back thirty years later over the Victorian age with its statesmen and thinkers, describes these as 'the best and greatest men whom I have ever known.' But what chiefly attracted the eyes of public men outside Scotland to the Free Church was its success as an experiment in the voluntary support of the church on the great scale—by means of contributions not local or congregational, but with a national altruism and solidarity. The foundation for this success was already laid in its Presbyterian constitution, which, as Lord Selborne observes, always enables a church, so long as it is not impeded from without, to exercise itself 'in the whole art and power of self-government, self-legislation, and self-expansion.' But the crisis called for new efforts and more powerful organisation. The order of deacons was restored or enlarged; an army of local collectors worked under them, and the money locally collected was paid into a central *Sustentation Fund* and equally divided among the ministers throughout Scotland. A hundred thousand pounds was subscribed for building the churches even before the day of the disruption: five hundred of them were built within the first year. Manses were erected; schools built for the schoolmasters, for they also had been obliged to leave the parish schools; colleges instituted for theological students, under professors now excluded by law from the universities; and a home mission or church extension scheme was founded, through whose influence the number of pastoral charges in the Free Church vastly increased. But the church found it impossible, even amid the struggles of its infancy, to confine itself within Scotland. All its missionaries throughout the world had left the state with it, and thrown up their emoluments; and schemes and funds for foreign missions, for colonial missions, for continental missions, for Jewish missions, and a special scheme for the Highlands and Islands were instantly and simultaneously started. That enthusiasm should initiate all this in the moment of suffering was, perhaps, not wonderful: what is more noteworthy is the permanence of the results. In 1900 there were 1070 regular charges in the church.

The history of the Free Church from 1843 reflected increasingly the general course of church life outside it in Scotland. In its earlier years it was much occupied, like every body on a national scale, with questions of centralisation as against local government. Thus, a controversy whether it should have one college or more was terminated by its adherents in Glasgow and Aberdeen liberally endowing, and so securing, the institutions in either city. In 1858 the *Cardross Case* arose, and created much interest, as raising legal questions affecting Free Church principles. But, while the earlier decisions of the Scottish courts in it appeared to threaten interference even with the internal action of churches, their later findings refused to the deposed minister of Cardross the means of prosecuting even that civil action of damages which the church professed their readiness to meet. In 1863 Dr Candlish and Dr Buchanan started the proposal of union with the United Presbyterian Church, which had by this time gathered into itself nearly all the Scottish secessions of the 18th century. Negotiations went on for years, and terminated in 1873 in a postponement of incorporating union, but with an obligation for a working agreement in the meantime, to include 'mutual eligibility of ministers from all the churches that had taken part in the negotiations. In 1874 patronage was abolished by parliament in the church established, without any proposed change upon the general Scottish law of church and state. The Free Church

Assembly at once resolved that disestablishment was the proper remedy for the divisions of Scottish Presbyterianism; and its union in 1876 with the Cameronian body (see CAMERONIANS) seemed to unite these ancient traditions with modern views. Theological questions of course retained their dominant interest; and in 1881 the church refused to retain Mr Robertson Smith as its professor in Aberdeen, while declining at the same time to affirm that his biblical views were heretical. This compromise was unsatisfactory to all sides. In 1889 a large committee was appointed to consider the question of revising the church's confession while maintaining its central doctrines of faith. Although its Highland ministers were well known not to agree with their Lowland brethren about the necessity for creed revision and union with churches that renounce the Establishment principle, on the resumption of negotiations for union with the United Presbyterian Church it became clear that the party insisting on maintaining in full the testimony of the church to the Establishment principle had decreased; from 1896 on increasing majorities voted for the union under the leadership of Principal Rainy. The two churches, each retaining its principles, finally agreed (the Free Church by a majority of 643 to 27, the United Presbyterians unanimously) to incorporation as the United Free Church; and though a small protesting party withdrew and claimed the name and rights of the Free Church, the union was consummated at Edinburgh in a joint assembly on 31st October 1900. In 1904, on appeal, the House of Lords confirmed the claim of the protesting minority, now organised as a separate church, to the property and funds of the Free Church, regarded as a trust for the maintenance of the original testimony of the church, to which the dissentients had (as on the questions of predestination and church establishments) adhered without any modification. After the judgment, government appointed a commission to advise as to the settlement of matters in dispute, as to property and other considerations, between the two churches. The result was an act (1905) appointing an executive commission to allocate between the churches all questions of property defined by the act, having regard to all the circumstances of the case, but subject to the provisions of the act.

See *Subordinate Standards of the Free Church*, with 'Claim of Right' and 'Protest' (1851); Buchanan's *Ten Years' Conflict* (1849); Taylor Innes, *Law of Creeds in Scotland* (1867); *Annals of the Disruption* (1877); Peter Bayne's *Free Church of Scotland* (1893); the reports of the case in the House of Lords and of the Royal Commission; M'Crie, *The Church of Scotland, her Divisions and her Re-unions* (1905); and the articles CHALMERS, CANDLISH, GUTHRIE, &c.

Freedom of a City. See BURGESS.

Freehold. Tenures of land in England are divided into free and base or customary. As free were reckoned the military tenure of knight-service and socage—now the normal lay freehold (see TENURE). Copyhold (q.v.) is now the only form of customary tenure. None but an estate for life or an estate of inheritance ranks as a freehold; a term of years, however long, is less than freehold. Now almost all freeholders hold of the crown. The freeholders of a county were constituent members of the ancient county court; they had formerly the right to vote in the election of county coroners; and freehold property of the value required by modern statutes is a qualification for jurymen and parliamentary electors, and for certain public offices.

Free Imperial Cities, in the German empire, were those cities which owed allegiance to none but the emperor, which exercised suzerain rights within their own territories, and had the right of sitting

and voting in the imperial diet. At first free cities were distinguished from imperial cities, the difference consisting in the fact that the former paid no feudal dues to the emperor, whereas the latter did. But from the 13th century there was practically no distinction, all towns which formed an integral part of the imperial polity of states being called free imperial cities. These cities, which had not a uniform municipal organisation, some being governed on democratic, others on aristocratic principles, were generally ruled by one or two imperial officers, called *Reichsvogt*, *Schultheiss*, or *Burggraf*. The peculiar privileges attaching to these cities were acquired in different ways—by creation of the emperor, by purchasing freedom from the minor prince or lord to whom they owed allegiance, by the dying out of the family of the territorial superior, or by force of arms. And they were lost by the corresponding opposite means: some towns were seized by the neighbouring lords, others passed by conquest out of the empire altogether, others voluntarily sold their privileges of freedom, others again were deprived of their position by the emperor as punishment for contumacy. The creation of free imperial cities was generally encouraged by the emperors, who found in them a useful means of checkmating the ambitions of the petty princes. But between the 13th and 15th centuries the majority of them succeeded in securing the office of *Reichsvogt*, *Schultheiss*, or *Burggraf* for their own citizens. In 1474 the free imperial cities formed two groups in the diet, the Rhenish and the Swabian; and they were formally constituted the third college of the diet after the Peace of Westphalia (1648). In February 1803 all the free imperial towns of Germany, except Hamburg, Lübeck, Bremen, Augsburg, Nürnberg, and Frankfurt-on-Main, lost their privileges; and of these Augsburg, Nürnberg, and Frankfurt ceased to be free imperial cities in 1806. In 1815, however, the three Hanse towns, together with Frankfort, were admitted into the German Confederation as free towns. But by the incorporation of Frankfort with Prussia in 1866 only Lübeck, Bremen, and Hamburg were left. These became states of the German reich, as empire and republic. See Wilson-King, *German Free Cities* (1914).

Free-lances were roving companies of knights and men-at-arms, who, especially after the Crusades had ceased to give them employment, wandered from state to state selling their services to any lord who was willing to purchase their aid in the perpetual feuds of the middle ages. In Italy they were known as Condottieri (q.v.). In Germany the name *Landsknechte* was given to a famous organisation of mercenary foot-soldiers, originally raised by Maximilian I. in 1487 from the inhabitants of his Austrian hereditary dominions. The name is not, as is commonly said, a corruption of *Lanzknechte* ('lancemen'), but was given to distinguish the men of the Austrian lands from the Swiss mercenaries. The Landsknechte played a distinguished part in the wars of the 15th and 16th centuries, but fell into disrepute after the Thirty Years' War.

Free Lovers. See PERFECTIONISTS.

Freeman is one who has inherited the full privileges and immunities of citizenship; *freedman*, one who has been delivered from the restraints of bondage, but who, usually, is not placed in a position of full social or even political equality with him who was born free. In old Rome, indeed, the equivalent for freeman (*liber homo*) comprehended all classes of those who were not slaves; but the distinction here pointed out was preserved by the application of the term *ingenuus* to him who

was born free, and of *libertinus* to him who, being born in servitude, was emancipated. As the organisation of Roman society survived the convulsions of the middle ages to a far greater extent in the towns than in the landward districts, where the institutions of Feudalism (q.v.) almost entirely superseded it, it is in the borough and other municipal corporations that we still find *freemen*, or persons inheriting or acquiring by adoption, purchase, or apprenticeship the rights of citizenship. In Anglo-Saxon England the freemen were divided into *Ceorls* (q.v.) and *Eorls* (see *EARLS*). See *BOROUGH*, *BURGESS*, *CITY*, *SLAVERY*. In the United States the term freedmen was used of the coloured people emancipated by the civil war. The duty of caring for those helpless people, finding them work, organising education, and preparing them for the privileges of freedom was thrown on the war department; and in 1865 an act of congress created in that department the bureau commonly known as the 'Freedmen's Bureau,' whose duties practically ceased in 1870. The founding of several seminaries for coloured persons, such as Howard University and Fisk University, was a permanent result of its work.

FREEMAN'S ROLL.—By the Municipal Corporations Act of 1835 it was provided that every person who, if the act had not passed, would, as a burgess or freeman, have enjoyed, or might have acquired, the right of voting in the election of members of parliament was to be entitled to enjoy or acquire such right as heretofore. And it was further enacted that the town-clerk of each borough should make out a list, to be called the *Freeman's Roll*, of all persons admitted burgesses or freemen, for the purpose of such reserved rights as aforesaid, as distinguished from the burgesses newly created by the act, and entitled to the rights which it newly conferred; these last were to be entered on another roll, to be called the *Burgess Roll*. See *BURGESS*.

Freeman, EDWARD AUGUSTUS, historian, born at Mitchley Abbey, in the parish of Harborne in Staffordshire, 2d August 1823, was elected scholar of Trinity College, Oxford, in 1841, and fellow in 1845. He held the examinership in the School of Law and Modern History in 1857 and 1863, and in the School of Modern History in 1873; and was created D.C.L. of Oxford in 1870, and LL.D. of Cambridge in 1874. In 1884 he became regius professor of Modern History at Oxford. In 1860 he had settled at Somerleaze, where he lived the life of a country gentleman, but travelled frequently (see his *Studies of Travel*, 1894); and he stood unsuccessfully for Mid-Somerset as a Liberal. He had Greek and Serbian decorations, and was a member of various academies. His principal work is his *History of the Norman Conquest* (5 vols. 1867-76), one of the greatest monuments of English historical learning, which shows its author to possess almost every requisite of an historical style save one—that of condensation. His other works include *A History of Architecture* (1849); *History and Conquests of the Saracens* (1856); *History of Federal Government* (vol. i. 1863); *History of the Cathedral Church of Wells* (1870); *Old English History* (1869); *Growth of the English Constitution* (1872); *Historical Essays* (3 series, 1872-79); *Comparative Politics* (1873); *Historical and Architectural Sketches*, chiefly Italian (1876); *The Ottoman Power in Europe* (1877); *Historical Geography of Europe* (2 vols. 1881); *The Reign of William Rufus, and the Accession of Henry I.* (2 vols. 1882); *Some Impressions of the United States* (1883); *English Towns and Districts* (1883); *Chief Periods of European History* (1886); *Methods of Historical Study* (1886); *Ecce!r* (1887); and an unfinished *History of Sicily* (i.-iii. 1891-93). He died of smallpox at Alicante, 17th March 1892.

The leader of 'the Teutonic school,' Freeman, placed too great reliance on the evidence offered by the language and institutions. His leaning is marred by its pedantry: his argument, by its iteration; while his insight and breadth of view are scarce proportional to his knowledge. He maintains a high ideal of the dignity of real history, and made unsparing onslaught on writers who subordinate the true to the picturesque. See his *Life and Letters* by Dean Stephens (2 vols. 1895).

Freeman, JOHN, poet, was born in London in 1880. His works include *Stone Trees* (1916), *Memories of Childhood* (1918-19), *Poems Old and New* (1920), *Music* (1921), *The Moderns* (criticism, 1916), *Portrait of George Moore* (1922), *The Grove* (1925).

Freemasons. The masonic brotherhoods of the middle ages were organised incorporations, not substantially different in their nature from the other guilds, governed by rules of their own, and recruited from a body of apprentices who had undergone a period of probationary servitude. Fable and imagination have traced back the origin of freemasonry to the Knights Templars, the old Roman empire, the Pharaohs, Hiram of Tyre and the Temple of Solomon, or even the times of the Tower of Babel and of the Ark of Noah. The masonic craft in reality sprang into being about the same time and from the same set of causes as other incorporated crafts; but a variety of circumstances combined to give it an importance and influence beyond the rest. Men skilled in the hewing and setting of stones were naturally prized in an eminently church-building age. Their vocation necessarily involved travelling from place to place in search of employment. Wherever a great church or cathedral was built the local masons had to be reinforced by a large accession of craftsmen from other parts; and the masons from neighbouring towns and districts flocked to the spot and took part in the work, living in a camp of huts reared beside the building on which they were engaged. A master presided over the whole, and was assisted by wardens having surveillance of the rest. A mason, therefore, after going through his apprenticeship and probations, could not settle down like other craftsmen among his neighbours and acquaintances, but must travel from place to place to find employment; hence it became desirable or necessary to devise means by which a person once a member of the fraternity might be universally accepted as such, without requiring, wherever he went, to give fresh evidence of his skill, or having to undergo a renewed examination on his qualifications. In order to accomplish this end, and to enable a mason travelling to his work to claim the hospitality of his brother-masons on his way, certain signs and words were conveyed to him, which he was bound to keep secret. This arrangement is the sole shadow of foundation for the popular notion that the masonic brethren were in possession of secrets of vital importance, the knowledge of which had been from generation to generation confined to their own order. It has been supposed that the possession of the masonic secrets enabled the masons to design the great cathedrals of the 13th and 14th centuries; whereas it is now certain that during the purest ages of Gothic architecture, both in France and in England, the architects were not members of the masonic fraternity at all, but either laymen of skill and taste, uninitiated in the mysteries of masoncraft, or oftener bishops and abbots. The masons who worked from the architect's design were, at the same time, not the mere human machines that modern workmen too generally are, but men who, in carrying out an idea

imparted to them, could stamp an individuality of their own on every stone. Architecture was then a progressive art, and the architect of every great church or cathedral had made himself acquainted with the works of his predecessors, and profited by experience, adopting their beauties and shunning their defects. The nature of the advance which architecture was then making has been compared by Fergusson to the advance with which we are familiar in the present day in shipbuilding and other useful arts. 'Neither to the masons nor to their employers, nor to the Abbé Suger, Maurice de Sully, Robert de Susarches, nor Fulbert de Chartres is the whole merit to be ascribed, but to all classes of the French community carrying on steadily a combined movement towards a well-defined end.' In Germany, however, the masons of the 14th century, who had attained a wonderful skill in carving and in constructing arches, overstepping their original functions, took to a great extent the office of architect into their own hands; and it is undeniable that the churches designed by German masons, though rich in the most exquisite workmanship, are not comparable in the higher elements of beauty to the works of non-masonic architects.

The epithet 'Free,' as applied to the craft, was originally used as an abbreviation of the term 'freemen masons'—free of their guild. Scotland possesses the earliest record of the presence of theoretical or speculative masons in mason lodges. This is shown in the minute of a conventicle of the Lodge of Edinburgh, held at Holyrood House in the year 1600.

The history of freemasonry has been overlaid with fiction and absurdity, partly from an exaggerated estimate of its importance in the development of architecture, and partly from a wish to connect medieval masonry with the institution that passes under the same name in the present day. Modern (or so-called 'speculative') freemasonry is an innocent mystification unconnected either with the building craft or with architecture. It is of English origin, and dates from the 18th century. According to its peculiar phraseology, it is founded in the 'practice of moral and social virtue'; its distinguishing characteristic is charity; in its most extended sense; and brotherly love, relief, and truth are inculcated by its precepts. In freemasonry there are three grades—apprentice, fellow-craft, and master-mason; there being peculiar ceremonies at the making of each; and it is only on attaining to the degree of master-mason that a brother enjoys the full benefits and privileges of the craft.

The 'Lodges' of Scotland profess to trace their origin to the foreign masons who came to Scotland in the 12th century to build the Abbeys of Holyrood, Kilwinning, and Melrose. Those of England go still further back, to an assemblage of masons held by King Athelstan, at York, in 926. The mother-lodges of York and Kilwinning were the parents of many lodges erected in different parts of Great Britain; while several of the pre-18th century Scottish lodges were self-constituted. Towards the close of the 18th century it was in some quarters (as by Robison in his *Proof of a Conspiracy*, &c. 1797) made a charge against freemasonry that under its symbolism was concealed a dangerous conspiracy against all government and religion. The accusation was probably groundless enough as regards British freemasonry; and so little effect was produced by it that, in an act passed in 1799 for the suppression of secret societies, an exception was made in favour of freemasons. On the Continent political intriguers may sometimes have availed themselves of the secrecy afforded by freemasonry to further their schemes. In 1717 a Grand

Lodge was formed in London, with power to grant charters to other lodges. Under its sanction the first edition of the constitutions of the fraternity was published. The Grand Lodge was for a length of time on an unfriendly footing with the lodge of York, in consequence of having introduced various innovations not approved of by the older lodge, and of having granted charters within the district which York claimed as its own. In 1782 the then Duke of Cumberland (brother of George III.) was elected Grand Master of the Grand Lodge; and on his death George IV., then Prince of Wales, succeeded to the office, which he continued to hold till he was appointed regent, when, it being considered unsuitable that he should longer exercise any personal superintendence, he took the title of Grand Patron. In 1813 an understanding and a union was brought about between the two rival Grand Lodges by their respective Grand Masters, the Dukes of Kent and Sussex. The fraternity has since been managed by the 'United Grand Lodge of Ancient Free and Accepted Masons of England,' consisting of the Grand Master, with his Deputy, Grand Wardens, and other officers, the provincial Grand Masters, and the Masters and Wardens of all regular lodges, with a certain number of stewards annually elected, who meet four times a year for the despatch of business, besides which there is an annual masonic festival, at which every mason is entitled to attend. The Grand Lodge of England has at present nearly two thousand lodges under its protection; King Edward VII. was its Grand Master from 1874 to his accession.

In Scotland the masons, when they were a real company of artificers, were, like other handicrafts, governed by wardens of districts appointed by the king. In 1593 a reorganisation of the mason lodges was effected under William Schaw, principal warden and chief master of masons, who in the following year confirmed the three 'heid lodges' in their ancient order of priority—Edinburgh first, Kilwinning second, and Stirling third. In 1736, the operative element in mason lodges having become absorbed in speculative masonry, the Grand Lodge of Scotland was instituted by the representatives of thirty-four lodges, by whom also William St Clair of Roslin was elected Grand Master, on account of his ancestors' alleged ancient connection with the mason craft as patrons and protectors. Priority was assigned to the lodges according to the antiquity of their written records. The Lodge of Edinburgh (Mary's Chapel), with its records dating from 1599, was placed first, and Kilwinning, possessing records from 1642, second. The Lodge of Kilwinning did not formally object to this till 1744, when it withdrew from the Grand Lodge and resumed its independence. On relinquishing this position in 1807 it was re-admitted into the Grand Lodge by the title of Mother Kilwinning, with precedence over the other lodges, and the Provincial Grand Mastership of Ayrshire confirmed in perpetuity to its Master.

Besides granting charters of affiliation, the chief use of the Grand Lodge, whether of England or Scotland, consists in its acknowledged authority to enforce uniformity of ceremonial and other observances, and to settle all disputes that may arise within the lodges under its charge. In Scotland the officers and members of the Grand Lodge are delegates from the respective lodges; the delegation being the masters and wardens or their proxies. As a source of revenue, for each member made by a lodge a fee must be remitted to the Grand Lodge, whereupon a diploma of brotherhood will be issued. There are upwards of six hundred lodges under the Grand Lodge of Scotland. The Grand Lodge of Ireland, instituted in 1730, exercises jurisdiction over nine hundred

lodges. There are funds of benevolence connected with each of the British Grand Lodges.

Modern freemasonry spread from Britain to the Continent, to America, and to India. It was introduced into France in 1721, into America in 1730, Russia in 1731, and Germany in 1740; and there are now Grand Lodges all over the world. Roman Catholics treat freemasonry as a pantheistic system, essentially opposed to belief in the personality of God, subversive of all legitimate authority, whether of the church or of the state—the hatching-ground of most of the revolutionary societies of continental Europe. Some French societies are frankly atheistic. It has been expressly condemned by bulls or encyclicals from seven popes, including Leo XIII. and Pius X.

The deep symbolical meaning supposed to be couched under the jargon of the masonic fraternity is as apocryphal as the dangers of masonry to government and order. A set of passwords and a peculiar grip of the hand enable the initiated to recognise each other, and give a zest to their convivial meetings; and, if the institution possesses any practical utility, it is in its enabling a mason, in a place where he is a stranger, to make himself known to his brother-masons and claim their protection and assistance.

Free Port, a port at whose wharves the vessels of all nations can load and unload free of customs duties and commercial charges, with the exception of the usual harbour dues. A free port is thus, from the commercial point of view, an open harbour in contradistinction to one that is closed to all vessels except those of the country in which it is situated, and from the administrative point of view financially a foreign territory within the state to which it politically belongs. In the middle ages free ports were established for the purpose of attracting trade to particular maritime centres, especially by Italy, France, Spain, Austria, and Portugal, at the period when the exploitation of their colonies for the benefit of the mother-country was the ruling principle in the commercial policy of those states. In the end of the 18th and the beginning of the 19th century free ports acquired a position of peculiar importance in consequence of the prohibitive measures which were at that time in force. Since then, however, they have decreased both in importance and in number. At the present time their chief use is that of entrepôts for facilitating the more convenient interchange and distribution of commodities destined for more or less distant markets. To all intents and purposes their utility has been destroyed by the rival system of bonded warehousing, which has always prevailed in England and the United States in preference to the other system (see BONDED WAREHOUSES). In 1899 the only free ports remaining on the continent of Europe were Trieste, Fiume, Hamburg and Bremen—the latter two having since 1888 only a

restricted area within the free port. Trieste and Fiume ceased to be free ports in 1891, while in that year Copenhagen was made one. Outside of Europe, Hong-kong, Menado in Celebes, Singapore, Georgetown (Penang), Amboyna, Banda, Ternate, St Thomas (West Indies), Livingstone in Guatemala, and Zanzibar, are, or were recently, free ports.

Freeport, capital of Stephenson county, Illinois, on the Pecatonica River, 121 miles WNW. of Chicago by rail, with a college and some manufactures; pop. 20,000.

Free-soilers, a political party in the United States, the outcome of the Wilmot (q.v.) proviso, founded in 1848 to oppose the extension of slavery to the territories. At Buffalo in that year they nominated Martin Van Buren for president and Charles Francis Adams for vice-president, who secured a popular vote of 291,000, but no electoral votes. In 1852 their candidates polled only 156,000 votes; but in the period of political agitation that followed the free-soil principles assumed great prominence, and were adopted by the Republicans, in whose party, on its organisation in 1856, the Free-soilers were absorbed.

Free Spirit, BRETHREN OF THE, a fanatical sect diffused (often secretly) over Germany, Italy, and France, between the 13th and 15th centuries. Their doctrine was a species of pantheistic mysticism, which they applied with fearless consistency to all the details of moral obligation. Often condemned as heretics, they suffered severely at the hands of the Inquisition; and were confounded with the Beghards (q.v.). See BROTHERHOODS.

Freethinkers, a term used loosely of all who reject belief in divine revelation, but especially of the Deists. See AGNOSTICISM, ATHEISM, DEISM, POSITIVISM, RATIONALISM, RELATIVITY OF KNOWLEDGE, SECULARISM; and J. M. Robertson, *History of Freethought* (3d ed. 1915).

Free-town, capital of Sierra Leone, is the best harbour in West Africa, a second-class British coaling station, and the headquarters of the British West African forces. The town is enclosed by a range of wooded hills, and, though the temperature is tolerably uniform, the climate is unhealthy, especially for Europeans. Pop. 44,000, mainly descendants of liberated negroes. The town was founded in 1787.

Free Trade. 'Free Trade' is often used in a loose popular sense as practically equivalent to freedom of contract and *laissez-faire*; and thus particular kinds of land laws, bimetalism, factory acts, and various regulations affecting labour and manufactures are spoken of as infringements of free trade. Nothing, however, is gained by giving such an extended meaning to a definite expression, perfectly clear and precise in the historical sense. Historically, free trade refers to a particular policy as regards international or foreign trade only, and its principal features are absence of differential duties, and of artificial encouragements, such as bounties, by which the home producer is favoured as compared with the foreigner in the same department. The essence of free trade is equality and uniformity in the financial treatment of home, colonial, and foreign produce of the same kind. Thus the imposition of taxes upon commodities merely for revenue purposes (e.g. the tax on tea in the United Kingdom) is not held to be an infringement of free trade. Similarly the absolute prohibition of the importation of certain articles, supposing that the production at home is equally prohibited (e.g. immoral books), would not offend against free trade in its historical sense.

The economic system opposed to free trade, and the essence of which lies in the preferential treatment of the products of the home country or of

certain 'favoured' nations, has received different names according to the objects professedly in view. When Adam Smith advocated the principles of free trade, he attacked the elaborate economic policy known as the Commercial or Mercantile System (q.v.). Of this system, protection to home industries was only a part. At least equal stress was laid upon a favourable balance of trade which was supposed to be indicated by a balance of the precious metals being due to a country. By this principle of a favourable balance a government was guided in framing commercial treaties and in the treatment of its colonies. At a later date, however, the use of the term protection was extended to cover practically the same ground as the expression 'Mercantile System,' which fell into disuse. Still more recently the name 'fair trade' has been invented to describe a mild form of the protective system, in which the basis of economic policy is supposed to be reciprocity or free trade only with such nations as grant similar privileges. Sometimes 'fair trade' is also held to include differential treatment of colonies by the mother-country as against foreigners, and is thus associated with schemes for imperial federation. It is worth noting that up to the beginning of the 19th century fair trade was the polite name for smuggling, and that, according to Adam Smith, 'to pretend to have any scruple about buying smuggled goods would, in most countries, be regarded as a pedantic piece of hypocrisy.'

The principal practical difficulty in deciding whether a tax is really opposed to free-trade principles arises in the case of the possible use of substitutes. If, for example, the cheaper kinds of foreign wines are being taxed avowedly for revenue purposes only, an indirect encouragement may at the same time be given to the production and consumption of beer in the home country. Again, it is difficult in many cases to find a fair common measure for home and foreign articles, and thus to make customs and excise duties really equivalent. In wines and spirits the alcoholic test alone is obviously unfair, but it is difficult to decide how much should be fairly allowed for other qualities. Nor will a simple *ad valorem* tax be a sufficient guide, because the effect upon demand of a rise in price is different in different cases. It may even be said that all taxation of those foreign goods which, from the nature of the case, cannot be produced at home (such as tropical products in the temperate zones) furnishes an artificial encouragement to home industries. If, for example, tea and coffee are rendered very dear by taxation, the use of aerated waters and home-made wines may be stimulated. The case of drawbacks, in which an excise duty is drawn back upon the exportation of the article taxed, presents similar difficulties. If the drawback really exceeds the tax already paid, it amounts to a bounty; and in fact most of the bounties given upon exportation are disguised in the form of drawbacks.

Taking free trade in this historical if somewhat narrow meaning, it is convenient to examine the general economic theory on which the policy rests before giving actual examples of free-trade policy and its opposite, protection. The question is, 'Why should a nation give no preference to its own subjects over foreigners in the financial treatment of commodities in general, or at least of some particular kinds?' It will be seen at once that the establishment of a universal negative in any question of practical politics is only possible by making very stringent assumptions as to the object or end of political union. Suppose, for example, that we accept the maxim of Adam Smith, that defence is of far more importance than opulence, we at once make out a *prima facie*

case for the encouragement of those industries—e.g. shipbuilding and navigation—which may be assumed indirectly to contribute to national defence; and we understand why Adam Smith considered the Navigation Acts to be the wisest commercial provisions in the statute-book. Similarly various other social or political objects may be thought so desirable that the state ought to use its influence, by adjusting industrial finance, in order to promote these objects. It may be argued, for instance, that the state should look to the conditions under which labour does its work quite as much as to the mere cheapness of the final product; and that a nation ought to consider much more than individuals can be expected to do the remote consequences of certain lines of industrial development. In this way the arguments for protection founded upon a variety of industries, the possible exhaustion of peculiar natural resources, the encouragement of the growth of towns and manufactures in young countries, must be deemed *prima facie* worthy of consideration; although, of course, it may prove in the sequel that free trade is much more likely than protection to attain these and other important social ends, in addition to cheapness and plenty.

It is necessary, then, in order to understand the purely economic theory of free trade, to omit provisionally, for the sake of simplicity, not only many possible objects of financial policy, but also various considerations of great social and moral importance. We must begin by regarding the primary object aimed at as the present acquisition of the means of satisfying material wants at a minimum real cost—that is to say, the question must first of all be considered from the point of view of the consumer for the time being. With this narrow view of the subject it is easy to establish the case in favour of free trade. For with freedom of competition no foreign commodity would be imported unless it could be sold at least as cheaply as when produced at home, and the natural result of competition would be to lower the price; hence, to discourage importation by differential taxation would be to raise prices by restraining competition. Again, to artificially encourage exportation by means of a bounty may by diminishing the supply in the home-market raise the price; and, if an increased supply can only be obtained at an increasing cost, this must be the result. But although free trade may result, as just shown, in present maximum cheapness, it may be objected that all cheapness is relative to the means of purchase—i.e. to income—and that, if the former is promoted by free trade, the latter is augmented by protection. And at first sight it seems plausible to argue that if a certain policy increases employment it increases earnings, and that employment must be increased by encouraging home industry at the expense of foreign. The refutation of this fallacy in its grossest form is one of the greatest triumphs of the so-called orthodox political economists. Bastiat, for example, in his famous petition of the candle-makers against the sun, in which it is ironically shown how much encouragement would be given to all the industries directly and indirectly concerned in the production of artificial light by shutting up windows, &c., has made clear the error involved in 'making work,' or in increasing obstacles in order to encourage employment. Again, whilst it is allowed by free-traders that protection to any particular industry may turn more labour and capital into that channel, and thus increase the gross earnings of those employed in it, it is maintained that on the whole, from the national point of view, there is a loss. In the first place, the very object of protection is to raise the price above what it would be if foreign imports were admitted freely,

and thus the large body of consumers (including other labourers) are taxed for the benefit of the small class of producers. Secondly, the labour and capital of the country are drawn from the channels into which they would naturally flow, and are thus on the whole less advantageously employed; in other words, the gross annual produce of the land and labour of the society is less than it otherwise would have been. If, for example, by the exclusion of foreign corn the price is raised, not only are consumers taxed by the rise in price, but the labour and capital devoted to the production of corn are drawn from other employments, in which more commodities might have been produced, and on balance exchanged for more corn. We thus arrive at the great maxim of free-traders, that imports are paid for by exports, and 'if you take care of the imports the exports will take care of themselves'—in other words, if foreign labour is encouraged by the free admission of foreign goods, still, *ipso facto*, the home industry must be equally encouraged, because goods, to an equal value must be made to be exported to pay for these imports. In fact, it is maintained that the home industry is more encouraged than otherwise would be the case, because there is less waste of labour, capital, and natural resources. A certain quantity of labour and capital devoted to the more careful cultivation of land would raise more agricultural produce, but if devoted to some kind of export, this export might obtain by exchange far more corn raised at much less expense on virgin soil.

To the statement, however, that a country need regard only its exports, preliminary objection may be raised on the same ground on which the above maxim itself is really founded—viz. that all trade is reciprocal, and that ultimately imports and exports are a form of barter. For it may be said that, unless a country's exports are sent by the best route to the best market, they cannot purchase so great a quantity of imports, and it is quite as reasonable to regard the export trade as active, and the import trade as passive, instead of the converse. Suppose, for example, to take an extreme case, all other nations effectually prevented the importation of English manufactures, England would be unable to pay for its imports, and imports must cease. And, without going so far, it may still be maintained (as by Adam Smith) that distant and roundabout trades are not so advantageous to a country as near and direct trades.

Apart from this objection the position of free-traders appears to be sound under the assumptions usually made. These assumptions, however, require careful statement. In the first place, it is assumed that labour and capital can without loss or difficulty be turned from a decaying into a thriving industry, and that, if any home product is displaced by foreign competition, 'something else' will be made with the same labour and capital. But it may be objected that every industry requires a certain amount of specialised capital and peculiar skill and training which cannot be transferred to other employments; capital and labour, for example, formerly used in agriculture cannot without great loss be turned into the manufacture of cotton goods. There is some force in this objection, and Adam Smith placed it under the possible exceptions to a general free-trade policy which he considered worthy of consideration. At the same time, as he points out, there is a tendency to exaggerate the difficulty of absorbing any surplus labour set free from an old industry, and at any rate the argument is one not for absolute protection, but for partial protection during a limited transition period, whilst labour and capital are being withdrawn. There is, however, a more serious objection to this assumption of the perfect mobility of

labour and capital from one industry to another. A merchant, as Adam Smith said, is a citizen of no particular country, and if capital and labour are supposed to move without any difficulty within the limits of one country, their migration from country to country cannot be considered, especially in modern times, to offer any insuperable difficulty. Thus, it is theoretically possible that under the stress of foreign competition agriculturists might take their labour and capital from the United Kingdom to the United States, instead of to the cotton-mills of Lancashire or the coal-mines of Northumberland. The result would be that a trade formerly conducted between the rural and the manufacturing districts of England would now be conducted between the latter and the western states of America. Nor is this migration of industries a pure theory; we find many examples in history not only of the transference of industries from one part of the same country to another, but also from one country to another. Whether this transference would have been prevented by protection is, of course, a matter for further inquiry; the point at issue at present is simply the possibility of the free-trade assumption, that any displaced capital and labour will find employment within the country, not being realised. The importance of the exception is seen from a popular argument, often used as a rough and ready proof of free trade—viz. that if protection is a good thing for one country against another, it must be good for one district, county, town, &c. against others in the same country. But the answer is obvious, that, although from the national point of view the migration of industries within the country is a matter of indifference, it is a matter of supreme importance to the districts affected; and historically it may be noted that in England, as in other countries during the medieval period, the towns adopted stringent protective measures against one another; and, although this parochial patriotism has disappeared to a great extent, the commercial rivalry of nations is as strong as ever.

It is worth observing that Adam Smith always emphasised the importance to a country of employing its capital, so far as possible, within its own borders, and if it were employed out of the country he ranked the relative advantages according to the nearness of the foreign locality and the frequency of the returns. And, in his view, it was not a question of profit, for he expressly says that greater profits may be earned in distant than in near trades, and in foreign countries than at home. But the point is that if the capital is employed at home the labour of the country finds employment at home, and the home country enjoys the things produced. Suppose, for example, that a large quantity of British capital is exported to make harbours, railways, &c. in a foreign state; greater profits may be earned, but so far there will be less employment for British labourers whilst the works are being made, and when they are finished the benefits of use will be enjoyed by the foreigner. Many of the successors of Adam Smith, in their eagerness to give free trade the simplicity of an axiom, have omitted from their argument the element of nationality, and have forgotten that there is a question of 'somewhere else' as well as of 'something else.' The great merit of Adam Smith is that he fully recognises at every stage of his reasoning the difficulties which spring from territory being of the essence of the modern nation; and instead of arguing simply (but illogically) that, because universal free trade would be good for the world at large, therefore it would be equally good for every part of it, he maintains that, taking everything into account, and giving due weight to the principle of nationality, the interest of a par-

ticular nation would be advanced by free trade and retarded by protection or artificial management on the part of government. At the same time, however, it may be admitted that in some respects Adam Smith's argument needs development, because no economist would now feel justified in laying so much stress as he did upon reasons drawn from a peculiar view of natural theology and an optimistic mode of regarding the operations of nature. No matter how strong may be the belief in the beneficent guidance of an 'invisible hand' which leads the individual, whilst pursuing his own interest, to promote that of the public, it is necessary to give more specific grounds, and of a more purely economic character, in deciding between two methods of taxation and two methods of conducting international trade. Certainly, too much reliance must not be laid on the general argument derived from a survey of life as a whole in an age in which nature has come to be regarded as 'red in tooth and claw,' and as working out its ends by a prodigal waste of suffering and misapplied effect. It will be found, however, that the principal result of Adam Smith's natural theology has been negative omission rather than positive error.

Taking the world as a whole at any particular time, we can easily see that free trade would give the most advantageous employment of labour and capital, because everything would be produced under the most favourable conditions; but the difficulty is to show that free trade is the best policy for a country which adopts Adam Smith's fundamental position as to the relative advantage of keeping capital and labour employed within its own borders. On this view it is not enough to show that under free trade the consumer would obtain maximum cheapness and the capitalist maximum profits, but we must also show that the nation makes the best use of its resources for its own members. The arguments relied upon by Adam Smith are partly positive and partly negative, the former being based on the power of the self-interest of individuals, and the latter on the weakness of governmental control. Every person, he says, naturally prefers to employ his capital in the support of domestic industry, but then this qualifying clause is added, 'provided always that he can thereby obtain the ordinary, or not a great deal less than the ordinary, profits of stock.' This leaves the position open to the attack that, by supporting foreign in place of home industry, the individual may obtain more profits; or more generally that profit, as Adam Smith himself often points out, is not synonymous with national advantage. But the objection is not so serious as at first sight appears. For, in the first place, if capital when employed at home does not obtain ordinary profits, a check will be placed on accumulation, and it is certainly more advantageous for a nation to employ some of its surplus capital abroad, or in encouraging foreign industries, than to have no surplus through forcing it to stay at home; secondly, it must be noted that most of those who support a protectionist policy, on the ground of encouraging home industry, estimate the encouragement given by the profit earned, and would to the last disapprove of any policy which would lead to less than the ordinary rate being obtained.

It may, however, be further objected that by protection to home industries, and by the prevention of the admission of certain kinds of foreign goods, more capital may be employed at home at the ordinary rate of profit. The usual answer is that this capital must be drawn from other more advantageous industries also at home; but in an old country in which profit is at a minimum and capital overflowing its channels this answer does

not hold good. It is true that the consumers of the protected article lose so much by the rise in price, but it may be rejoined that to the nation this loss is more than compensated by the increase in the field for employment. Again, take a simple hypothetical case. Suppose that a new country yields only agricultural produce, and exchanges part of this for manufactures. If it imposes protective duties on manufactures, and if it can provide, through the growth of wealth and population, the necessary labour and capital without diminishing the amount of agricultural produce, the result is that its agricultural labour supports its own instead of foreign cities. Under the supposition made, the agriculturists will obtain less home manufactures than they would have done from abroad, at least for a time, but it is possible that the diversion of labour and capital may ultimately result in more wealth. In the ordinary argument for free trade sufficient allowance is not made for the growth of capital and population, nor for the advantages to be gained from employing them within the country. The question is regarded exclusively from the point of view of the consumer, under the hypothesis of a fixed amount of labour and capital already fully employed in the most advantageous manner.

The theoretical exception to free trade which has just been considered may be strengthened by the argument drawn from the stimulus given to production by a variety of industries, and by promoting trade directly between the towns and the neighbouring country districts, a consideration which was the basis of Wakefield's scheme of colonisation. It is urged, especially in the case of new countries, that, unless towns are encouraged by the protection of manufactures, there will not be a ready market for all the by-products of agriculture.

At this stage it may be well to note the other principal exceptions which have been taken to free trade from the nationalist standpoint. It is said that every nation should retain for the benefit of its own people any peculiar natural resources, and if possible also any inventions and artificial means of production. In the United Kingdom, for example, one of the principal causes of commercial supremacy is always said to be the close proximity of excellent coal and iron fields. But coal and iron are exhaustible, and the more they are exported so much the sooner will the point of exhaustion be reached. It is maintained that in the interests of posterity we should sacrifice the profits of a present trade and restrain the exportation. Carey even argues that the continuous exportation of all raw produce is practically equivalent to the exportation of the soil. In former times the wool of England was supposed (though, as is shown in Smith's *Memoirs of Wool*, probably without good cause) to be much superior to that of other countries, and accordingly, after being for some centuries the great staple of export, the exportation was later on forbidden under most severe penalties, and similar penalties were imposed on the exporters of sheep and lambs. The same policy was carried out in reference to machinery and the instruments of production generally, including 'the living instrument' man. The answer made to this case of protection on the part of free trade is that it is impossible to tell, as regards the remote future, whether the peculiar advantage attaching to natural resources will continue (e.g. coal with the development of electricity from other forms of energy), and that, as regards instruments, they can be copied and imitated although the actual exportation is prevented. It is also argued that restraints upon the production of machinery by limiting the market will tend to check the progress of invention.

Another exception to free trade has been made on the ground of national independence. As already noted, it was on this ground that Adam Smith approved of the Navigation Acts. Recently the increasing dependence of the United Kingdom upon foreign nations for its food-supplies (see FOOD) has attracted much attention, and has led to proposals for differential duties in favour of the colonies. The same argument was the principal one used in the long agitation which resulted in the repeal of the Corn Laws. The answer is that cheap food is of such importance to the masses of the people that nothing which would raise its price would be assented to, and that indirectly through the growth of wealth and population under the stimulus of cheap food the nation has become much stronger than it would have been if it had tried to preserve its independence. Further, it is said that the dependence is really mutual, and that the food-growing countries rely upon selling their food to obtain clothes and other necessities just as much as the importers of food rely upon them.

A favourite exception to free trade is that a nation ought to consider principally, not the cheapness of goods to the consumer, but the effect of the conditions of labour upon the producer. No nation would be content with being the hewer of wood and drawer of water to the rest of the world, and the more a nation is composed of highly-skilled workers engaged in healthy, pleasant, and energising occupations, so much the better. It is assumed that, if by protective or prohibitive duties foreign wares of the higher class be excluded, they will be produced at home by native artists and craftsmen. It is, however, more probable that many of the articles would not be produced at all, and that in any case the absence of the foreign stimulus would eventually check the higher industrial development. If, for example, foreign paintings were excluded from a country to encourage painting, and engravings to encourage engraving, and so on, it is more than probable that the art of the country in question would lose not only in quality but in quantity. It may also be pointed out that the best way to promote the higher forms of industry is not by the simple process of exclusion, but rather by an elaborate system of technical and artistic education. The protectionist is always in danger of forgetting that it is not enough to show that certain ends are worthy of attainment, but that he must also prove that the rough and ready device of excluding foreign competition is the best means to adopt.

At this point it is convenient to complete the positive argument in favour of free trade. Hitherto the question has been regarded on the free-trade side mainly from the point of view of cheapness to the consumer, whilst abundant and varied employment for the producer and other important social aims have only been considered as possible grounds of exception to a free-trade policy. But Adam Smith, especially, and many of his successors have supported free trade with these objects professedly aimed at by protectionists always in view. Freedom of action and freedom of movement free-traders hold to give the greatest encouragement to the development of enterprise, and to the progress of invention, and thus indirectly at least to the employment of labour in a variety of industries. The natural result of free trade is to increase the efficiency of labour and capital through the stimulus of open competition, whilst the natural result of protection is to establish routine methods. Here it is important to observe that the practical abandonment of the wages-fund theory, according to which wages were supposed to be paid simply out of pre-accumulated capital, for the theory that wages are paid out of the price of the produce of labour, renders the usual statement of the theory of free trade, from the standpoint of

capital only, incomplete and one-sided. The new theory of wages adds, however, much force to the position that the efficiency of labour is, on the whole, increased by free trade and diminished by protection. Again, under free trade an industry which ceases to be profitable, and to satisfy consumers, on the opening up of foreign markets is soon abandoned with a loss only to those engaged in it at the time, whilst under protection vested interests are created, and the loss is perpetuated. It must, however, be allowed that this argument from the absence of the stimulus of competition under protection loses force in proportion to the area, wealth, and population of the country to which it is applied. In the United States, for example, there is abundant scope for competition, and the same remark applies to a possible federation of the colonies and dependencies of the British empire.

On the whole, then, so far as the positive arguments are concerned, by which free trade is generally supported, it must be allowed that it is easy from the national standpoint to discover hypothetical exceptions, which might be thought, to adopt Smith's language, 'worthy of deliberation.' And, contrary to the popular opinion in England, most economists of repute have allowed theoretically that under certain circumstances a country might gain by stepping aside from a general policy of free trade. Adam Smith, in addition to the exceptions already noted, approves of retaliation, if by that means a great market might be secured for exports; Ricardo points out a mode by which a country might gain by the monopoly of its colonial trade, and J. S. Mill allows that the Navigation Acts, though economically disadvantageous, were politically expedient, and also supports the argument derived from Adam Smith in favour of temporary protection, with a view to the more speedy development of industries for which a new country seems naturally adapted. One of the most systematic of English writers on the subject, Professor Sidgwick, expressly says that, when the matter is considered from the point of view of abstract theory, it is easy to show that protection, under certain not improbable circumstances, would yield a direct economic gain to the protecting country.

But it must always be remembered that the positive argument in support of a general free-trade policy is only part, and probably the least important part, of the case. It is one thing to allow that, provided a government is perfectly wise and able at once to change its policy according to the variations of industry, it might use its power in such a manner as to direct the capital and labour of the country into more advantageous channels than those of pure free trade; but it is quite another thing to admit that any government would be capable of managing the industries of a great nation in this way. Those who quote Adam Smith for his theoretical exceptions forget that he always laid most stress on the negative side of the argument—that is to say, on the weakness and incapacity of governments. 'The statesman,' he writes, 'who should attempt to direct private people in what manner they ought to employ their capitals, would assume an authority which could safely be trusted not only to no single person, but to no council or senate whatever.' The clearest illustrations in support of this position are found in the commercial history of England. Even in the middle ages, when changes were comparatively slow and competition was fettered in all directions by custom and routine, the government was unable to carry out the objects which it had in view in protecting certain native industries. It is worth noting also that several important manufactures took their rise through imitation of foreign wares, under the guidance of foreign workmen, in direct

opposition to the supposed interests of home producers. It is a curious fact that precisely that part of the old commercial system which was most approved of by Adam Smith—viz. the Navigation Laws—was the first to be seriously attacked on the ground of the practical difficulties involved. These acts naturally induced foreign nations to retaliate, and the attempt to obviate this difficulty by means of reciprocity treaties led to still further complications with other countries. Apart from the peculiar practical difficulties that arise in particular cases, certain general reasons may be given why protection is likely to fail when everything is taken into account. The taxation for protective purposes of any product necessarily involves the taxation of substitutes; and since in general a duty so far as it is protective is not productive of revenue, for the main object of protection is to exclude the foreign product, there is the expense of supervising and guarding against the evasion of a number of unproductive taxes. Apart from these indirect evils, the real incidence of import duties is extremely difficult to determine. Again, in every industry there are always a certain number of producers and traders on the margin of bankruptcy, and they ascribe their failure to the insufficiency of the duties. Thus a duty which at first might have been proposed as a temporary expedient tends not only to become perpetual, but to increase. It is well known, for example, that under the old Corn Laws there was a constant demand for increasing protective duties. Those actually engaged in any industry at the time when protection is given may gain immediately through obtaining a practical monopoly of the market, and exceptional profits and wages may be obtained until they are reduced by competition. But when those employed in other industries see this apparent advantage obtained by the favoured industry, they also naturally clamour for protection, and thus the interference of government once begun spreads with increasing rapidity, a fact which has found illustration in every protectionist country. The insuperable practical difficulty is not only to decide on national grounds what industries should be protected, but afterwards to persuade those engaged in other employments that they do not require protection. Hence it is easy to understand why under the old system England and other countries were practically compelled to impose a general duty upon all foreign manufactures not specially taxed. Thus the general result of protection is to stifle foreign trade, and indirectly, by curtailing the market for exports, to fetter home industries. To render the negative argument in support of free trade complete, it would be necessary to take into account also the more general arguments advanced in support of natural liberty as against governmental interference—e.g. the increasing burdens of the necessary functions of government with the progress of civilisation, the dangers of the increase of power by increasing the functions of officials, the evils of restraints upon individual liberty, &c., which obviously have an important bearing upon the particular case of protection, but which are too general to be more than indicated in a special article. When on the one side the simplicity of free trade is considered, and on the other a complete survey is made of the practical difficulties involved in protection, compared with the doubtful advantages to be gained in the exceptional theoretical cases noted, and when it is borne in mind that the objects avowedly aimed at by protectionists—e.g. variety, skill, national independence, &c.—are much more likely to be obtained by other social methods under the system of natural liberty than by the simple device of imposing heavy taxes on foreign goods, a strong case is made out on balance for adopting

free trade as the general rule of industrial policy; and in all probability free trade would have been more generally adopted, if the economical arguments had not been overshadowed by political prejudices, resting on very different foundations.

The question of Free Trade and Protection is discussed at length in all the text-books on political economy; and to PROTECTION we ourselves devote a special article. The introductory essay in Macculloch's edition of the *Wealth of Nations* (1828; new ed. 1857), still the great storehouse of facts and theories, gives a good account of the literature of the subject previous to Adam Smith. The principal subsequent addition to the arguments for free trade is the theory of foreign trade in Ricardo's *Principles* (1817), developed by J. S. Mill, Cairnes, and more recently by Professor Bastable, and criticised somewhat adversely by the French mathematician and economist Cournot, and by H. Sidgwick. Popular expositions of free-trade principles are well represented by Chevalier's *Examination of the Commercial System known as Protective*, Bastiat's *Sophismes économiques* (Eng. trans., *Popular Fallacies regarding General Interests*, 1846), Sir Thomas H. Farrer's *Free Trade versus Fair Trade* (1885), Fawcett's *Free Trade and Protection* (1878; 6th ed. 1885). The history of the free-trade movement in England is given in Lord Morley's *Life of Cobden* (1881). For the fiscal controversy 1903–10 see *A Project of Empire*, by J. S. Nicholson (1909); *Free Trade in Being*, by Russell Rea (1908); *The Case against Tariff Reform*, by E. E. Todd (1911). For the question in the light of the war—*Report of the Paris Economic Conference* (1916); *Final Report of Committee on Commercial and Industrial Policy after the War* (1918); *The New Tariffism*, J. M. Robertson (1919).

Free-will. See WILL.

Freezing Mixtures. When matter passes from the solid to the liquid, or from the liquid to the gaseous (or vaporous) state, a considerable quantity of heat in general disappears or is rendered 'latent,' owing to the fact that, energy being required to effect these changes of molecular state, it is taken from the energy in the form of heat already existing in the substance; and this abstraction of heat causes a fall of temperature (see HEAT; MATTER; GAS AND GASES). This property is taken advantage of for the production of low temperatures. The solution of a salt in a liquid, and the liquefaction of two or more solid substances when mixed, are both examples of the change from the solid to the liquid state, accompanied by a lowering of temperature, unless this be neutralised by heat developed by some purely chemical action. The following table gives the composition of freezing mixtures commonly in use. The solid materials should be finely powdered and intimately mixed together in a vessel of low thermal conductivity. The first column of the table gives the components in each mixture; the second their relative proportions by weight; in the third the resulting temperature (Centigrade) of the mixture, assuming that, with the exception of snow or ice, the temperature of the materials previous to mixture is 10° C. The fourth column gives the diminution of temperature in degrees Centigrade:

Components.	Relative proportion by weight.	Temperature of mixture	Diminution of temperature.
Water	1	16°	26°
Ammonium nitrate..	1		
Snow or powdered ice.....	5	..	20°
Common salt.....	2		
Snow or powdered ice.....	1		
Calcium chloride, crystals.....	2		45°
Ammonium nitrate.....	1		
Sodium carbonate.....	1	14°	29°
Water.....	1		
Sodium phosphate.....	27		
Ammonium nitrate.....	18	20°	39°
Fuming nitrous acid.....	8		
Water.....	4		
Sodium sulphate.....	8	18°	28°
Hydrochloric acid.....	5		
Snow.....	5	32°	42°
Hydrochloric acid (at 0° C.).....	5		

Such mixtures are only applicable where a low temperature is required for a short space of time, and are of no use where a continuous process of refrigeration is necessary. For this latter purpose the low temperature produced by the expansion of gases and vapours is chiefly used, the principal substances employed being water, ether, ammonia, and carbon bisulphide. An account of these processes, and of the apparatus connected with them, will be found under REFRIGERATION. Low temperatures are also obtained by the evaporation of a liquid, either under artificially diminished pressure, or where its vapour pressure is constantly small, the energy necessary to effect the change of state being taken from the heat in the substance itself. The evaporation (and consequent cooling) of water from the surface of porous earthenware vessels, called water-coolers, is due to this principle. The same is true of the formation of ice in shallow lakes at night in tropical climates.

Low temperatures reached by Natterer and others, in their experiments on the liquefaction of gas, were obtained by a mixture of solid carbonic anhydride and ether; or of solid nitrous oxide and carbon bisulphide. By such means the temperature of -140°C . was reached. Lower temperatures can be obtained by other methods. See GAS; also COLD, FROST, ICE, MELTING-POINT, TEMPERATURE, THERMOMETER, WATER.

Freiberg, an old German mining centre, is situated on the northern slope of the Erzgebirge Mountains, at a railway junction, 20 miles SW. of Dresden. The existing cathedral, built in the late Gothic style, on the site of an earlier one (burned in 1484), contains tombs of the Saxon electors of the Albertine line, and has a Romanesque portal called the Golden Gate. The town owes its origin to its silver-mines, discovered about the year 1163. Parts of the ancient walls and flanking towers still remain. At the school of mines, founded in 1765, the most famous institution of the kind in Europe, instruction is given in surveying, mining, the preparation of ores, geology, mineralogy &c. It possesses a laboratory, a library, a collection of mining models, and mineralogical and geological collections. The mineral ores extracted near Freiberg are silver, bismuth, nickel, cobalt, zinc, arsenic, &c. The manufactures consist principally of gold and silver ware, wire, chemicals, machines, leather, and cigars. Founded in 1175, Freiberg suffered more than once in the Thirty Years' War and the Seven Years' War. Pop. (1875) 23,559; (1890) 28,995; (1900) 30,175; (1910) 36,237; (1919) 32,981.

Freiburg, or FRIBOURG, a canton of Switzerland, bounded on the N. and E. by Bern, and on the S. and W. by Vaud and the Lake of Neuchâtel, with three enclaves in Vaud. Area, 644 sq. m.; population, 143,000, principally of French descent and Roman Catholics in religion. The official language is French, but all the laws and decrees binding on the whole canton are published in both French and German. The surface is hilly, the canton being invaded by offshoots of the Bernese Alps, which rise to upwards of 7000 feet in height. The river Saane or Sarine, a tributary of the Rhine, traverses almost the whole extent of the canton from its southern to its northern extremity. The country abounds in excellent meadows and pastures, upon which are reared fine breeds of horses and cattle. Dairy-farming, especially cheese-making (Gruyère), is pursued with great success. The other chief pursuits are agriculture, watch-making, and straw-plaiting. Timber, cheese, and cherry brandy are exported. Freiburg was received as a member of the Swiss confederation in 1481, and in 1848 a liberal constitution was established,

but revised in a reactionary direction in 1857. It sends six members to the national council.—The capital is Freiburg, or Fribourg, on the Saane, 19 miles by rail SW. of Bern. The town is built in the valley and up the slopes of the hill to the edge of the precipice overhanging the river. The banks of the Saane (Sarine) are united by a stone and concrete bridge. The church of St Nicholas, a fine Gothic structure, begun in 1283, has one of the finest-toned organs in Europe, and a lofty belfry. There is a university. Pop. 20,000.

Freiburg IM BREISGAU, a town of Germany, in the land of Baden, is situated on the western edge of the Black Forest, 32 miles NNE. of Basel. It is an open, well-built town; the walls and ditches with which it was formerly surrounded have been converted into promenades and vineyards. The cathedral, one of the most beautiful and perfect specimens of Gothic architecture in Germany, cruciform in shape, and built of red sandstone, was begun in 1122, but not completed till 1513. Its western steeple, 381 feet high, is remarkable for its elegance and lightness. The university, which was founded in 1455, has about 150 professors and teachers and 3000 students. The chief manufactures are sewing silk, cotton and thread, buttons, beads, chicory, paper, parquetry, &c. Wine and timber are the chief articles of trade. Pop. (1865) 19,085; (1919) 87,946, of whom more than one-half are Protestants. Freiburg is the seat of a Catholic archbishop. Founded in 1091 by the Duke of Zähringen, and created a town in 1115, Freiburg has repeatedly changed masters; twice it was given over to France (1679–97 and 1744–48). It also played an eventful part in the Thirty Years' War. In 1806 it fell to Baden; and in 1848 the Baden revolutionists were defeated here by the troops of the German confederation.

Freight is the reward paid to the owner of a ship for the carriage and safe delivery of goods. A person chartering a ship pays freight for the goods sent by it, and dead freight in respect of any deficiency of cargo; the terms of the agreement are fixed by the Charter-party (q.v.). A person sending goods by a general ship pays freight for them; and the contract takes the form of a bill of lading. So far as the rights of parties are not made the subjects of positive stipulation in the contract of affreightment, they are ascertained with reference to the usage of trade. The carrier's duty is to have the ship ready to start at the time appointed (wind and weather permitting), and to receive the goods and carry them to their destination; having performed these duties, he has a lien on the goods and a right of action in case of non-payment of freight. The shipper's duty is to have his goods forward in time. Freight is not usually payable unless the voyage is completed; but it is sometimes prepaid, in whole or in part, at the risk of the shipper. It was formerly held that the wages of the crew depended on the earning of freight by the ship; as Lord Stowell expressed it, 'freight was the mother of wages.' This rule has been finally set aside by the Merchant Shipping Act, 1854. Even in case of shipwreck a seaman may recover his wages; but his claim will be barred if evidence can be given to show that he failed to exert himself to the utmost to save the ship and cargo. The old rule is adhered to in America; but it does not apply to the master, nor does it apply to seamen if freight has been lost by the fault of the master or owners. Freight may be made the subject of insurance. See CARRIER, INSURANCE.

Freiligrath, FERDINAND, a poet of Germany, was born at Detmold, in the principality of Lippe, 17th June 1810. The favourable reception accorded

to his first collection of *Poems* in 1838 induced him to abandon commercial pursuits and devote himself to literature. From this time onwards he led a very unsettled life. In the poetry of this his earlier period it is the originality both of subject and of treatment, the oriental glow of the diction, the energy of the descriptions, and the finish of form that have secured the poet fame. But about the year 1844 a great change came over the spirit of his writing. Freiligrath was drawn into the political contest of the period as a bold champion and singer of democratic opinions. The publication of his radical *Glaubensbekenntniss* ('Confession of Faith'), in the same year, compelled him to take refuge in Belgium. In 1846 he repaired to London, and, although two years later he celebrated the revolutionary movement in the poems *Die Revolution* and *Februarklänge*, he was nevertheless included in the amnesty of March 19, and returned to Germany, settling at Düsseldorf, where he became the leader of the democratic party. Shortly after, he was impeached on account of his poem, *Die Todten an die Lebenden* ('The Dead to the Living'), but after a celebrated trial acquitted, 3d October 1848. Nevertheless, a second prosecution in 1851 compelled him to flee once more, and he again took refuge in London. Nor did he return to Germany until 1868. His last years were spent at Stuttgart and Cannstatt, where he died 18th March 1876. In his later years Freiligrath returned in some respects to the style of his first work, a decided contrast to the somewhat strained and artificial poems of his political period, chief amongst which are *Ga Ira!* (1846) and *Neuere politische und sociale Gedichte* (1851). The latest poems were published as *Neue Gedichte* (1876). Freiligrath is also memorable as a translator from the English, particularly by his renderings of Longfellow, Shakespeare, &c. The popularity of his earliest book, *Gedichte*, is attested by its fifty editions before the end of the century. A complete edition of his works appeared at Stuttgart

(6 vols. 1870; 5th ed. 1886). See his *Life* by Schmidt-Weissenfels (1876), and Buchner (1881).

Freischütz ('free-shot'), the name given to a legendary hunter and marksman who gets a number of bullets (*Freikugeln*) from the devil, six of which always hit the mark, while the seventh is at the absolute disposal of the devil himself, who directs it at his pleasure. A northern variant makes the man a fowler who sells his soul to the devil for an unerring aim for seven years. Fortunately there is one condition—that the enemy should always be able to name the game being shot, and the fowler's wife, seeing in this a way of escape for her unhappy husband, strips, tans, and feathers herself, and so outwits the devil to her husband's salvation. The story was first treated by Apel in the first part of his *Gespenssterbuch* (1810), and was adapted by F. Kind for the opera, *Der Freischütz* (*Fr. Roland des Bois*), which the genius of Weber has given to the world. See Grasse, *Die Quelle des Freischütz* (Dresden, 1875).

Freising, a town of Bavaria, on the Isar, 22 miles NNE. of Munich by rail, with 16,000 inhabitants, and manufactures of threshing-machines and hand-mills, turf-cutting, and book-printing (since 1495). The chief buildings are the beautiful cathedral (1160) and the former episcopal palace (now a theological seminary). Close by is an old Benedictine abbey (725–1803), now a model farm, with schools of brewing and horticulture. The bishopric of Freising dated as far back as 724 A.D., and its bishops were made princes of the empire in the 17th century, their authority embracing an area of 320 sq. m.; the see was secularised in 1802.

Freistadt (Hung. *Galgóc*), a market-town of Czechoslovakia (till 1920 Hungary), 35 miles NE. of Pressburg, on the left bank of the Waag, opposite the fortress and prison of Leopoldstadt. Pop. 9000.
